JOURNAL OF HORTICULTURE,

COTTAGE GARDENER,

AND

HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING BEE-KEEPING.

EDITED BY JOHN WRIGHT, F.R.H.S.

Established in 1848

VOLUME XXXV. THIRD SERIES.

JULY — DECEMBER, 1897.

LONDON:

PUBLISHED FOR THE PROPRIETOR, 171, FLEET STREET.

LONDON :

PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,

171, FLEET STREET.

TO OUR READERS.

"Time travels quickly" was the motto inscribed by a celebrated man on his last Christmas card—the late and widely-mourned Sir Frank Lockwood. Under his gay wisdom was a vein of seriousness, and he lived long enough to discover the great truth above recorded.

Quickly, indeed, do the days and months pass; and especially, perhaps, to those who enjoy them the most, and who are also advanced on their life's journey; nor does time hang heavily even to the young when it is occupied pleasantly, for then it seems to glide away all too soon.

In what pursuit can more pleasure be found of the most wholesome and satisfying nature than in that of gardening—satisfying, yet its votaries never satisfied; those who love the delightful and beneficent art, and pursue it successfully in some of its aspects and according to their means, rejoice in what they are able to accomplish; but their present pleasure is scarcely greater than that which they have in prospect.

The results of many efforts are seen and afford satisfaction, but those of other plans and methods in procedure are not yet developed; the future then is full of interest and hope, quickened day by day as the period of realisation approaches. Should this exceed anticipations, is the ardent amateur or gardener satisfied? No; he is gratified, and resolves to strive for greater achievements.

When the hopes are not fulfilled in the first endeavour, the intellect is stimulated to find the cause of a partial failure, and also to seek a safer course to follow in the future. The student and worker may have made a mistake, but gathers courage and perseveres, as he well may, because, has it not been said that "a man who never made a mistake never made a discovery?"

Another aspect remains to be noticed, namely, it is the rule, which the few exceptions only make the clearer, that those who derive real pleasure in gardening, and are made happier by indulgence in it, desire that others should be made as happy as they; and thus we find various methods resorted to for obtaining new recruits to strengthen the ranks, and endeavours made to guide them along safely by the light of experience.

This is done by personal intercourse, by mutual associations, by exhibitions, and through the agency of the press For nearly fifty years the *Journal of Horticulture*, though not always under the same title, has enjoyed a large share in the distribution of knowledge and information of interest, and also, we would fain hope, of benefit to the gardening community.

We honour the veterans who happily are still with us; we recognise with admiration the ability and zeal of earnest workers in the prime of manhood; we congratulate the probationers on their commendable efforts; and we thank all most cordially, amateurs and professionals, regulars and volunteers, of whatever age or station, at home or abroad, for their valued co-operation in widening the interest in, and sustaining the usefulness of, the medium that has long been, and still remains, a welcome guest in the homes of the wealthy and the workers who derive pleasure or profit from the grand old art of gardening.

Journal of Horticulture.
THURSDAY, JULY 1, 1897.

JUBILEE REFLECTIONS.

Founders of our Faith.

FOR a brief space, ere the ringing notes of Jubilee cease to vibrate—those notes which have made no uncertain sound in our own domain, as evidenced by the right royal number of the *Journal of Horticulture* of last week, June 24th—it seems a fit and proper thing to turn up the pages of the long past, and give a passing recognition to those who have "allured to brighter worlds and led the way." In doing so, if it does not inspire, it may at least impress our young men with the extent of those herculean tasks which were grappled with in the dark, compared with the light of literature illumining these latter days. That there were giants in those days most will admit, but it is less easy to recognise the extent and the number of the difficulties those pioneers overcame, for we have no present parallel to judge them by.

Three hundred years ago, in 1597, John Gerarde published his "Herbal," thus marking an era in horticultural history, and which appears to be, so far as our own country is concerned, the first record of its kind of any importance which is preserved to us. Truly Gerarde's "Herbal" is apt to be regarded by us as little more than a literary curiosity, but upon reflection due justice may be afforded to the memory of this grand old gardener in weighing his production against contemporaneous works and inventions.

Gerarde was undoubtedly a gardener in every sense of the word, and like various men who have trod the same path through the intervening centuries, and left more brilliant tracks behind them, also studied the art of healing, for his somewhat scant biography tells us that he was a surgeon, as well as, for many years, chief gardener to My Lord of Burghley, who had the best collection of plants in the kingdom, including a great number of exotics, introduced by him—Gerarde. History also tells us that the "Herbal" was brought out at the expense of one J. Norton, who procured from Frankfort the blocks in wood, which were used in the "Herbal" of Tabernæmontanus.

Quaint as these may now appear to us, they must for that time have been highly skilled

productions, it being easy to identify many of his curious descriptions by them. In this, the tricentenary of Gerarde's "Herbal," and whilst this unique Victorian reign is being honoured to the confines of the Empire, though shorn of much of the pomp and pageantry surrounding the Virgin Queen, it is easy to link this humble ray of the long ago with the brilliant scintillations of literary light surrounding the sceptre of our own illustrious Sovereign. All honour then to Gerarde, the pioneer penman of the subject we love.

Stretching far, far back to the fourth century B.C., we may note the earliest known attempt to bring the objects of the vegetable kingdom within the pale of science by that eminent pagan philosopher Aristotle, but no definite results appear to have obtained until comparatively recent times, and these it is not difficult to trace to the study of medicine. Those who studied medicine were led to study plants, which latter, in the most remarkable instances, became the all-absorbing passion of the student's life. But a few of the honoured names associated with our subject can be included here, and those few are chosen more with the object of pointing a moral to young labourers in the great garden of Nature than to adorn a tale whose chapters, as far as we can see, will never be finished.

In 1656 was born Joseph Pitton de Tourneforte, of a noble French family, who at the early age of twenty-one obtained his heart's desire and pursued the study of botany amid many dangers and privations among the Alps and Pyrenees, forming a large collection of plants, and making many important observations. Due recognition awaited him by being appointed assistant professor to M. Fagon, then curator of the Jardin de Roi. In 1688 he made further explorations in Southern and Western Europe, to the further enrichment of the royal gardens, and finally his ripened experience and leisure were devoted to composing several comprehensive works, which marked a distinct advance in the methods of classification employed by his predecessors. De Tourneforte, who died in 1708, furnishes us with a striking example of that love of Nature which led him to early abandon a luxurious life and become her ardent and accomplished pupil. In 1682 Ray proposed the classifying of plants according to the natural system; laying, in fact, the foundations upon which Jussieu, De Candolle, Brown, Lindley, and others, have brought the system to its present perfection.

It is with reverential feelings one now approaches a name holding a unique position in the annals of our subject—if not in the history of the world; this is Linnæus, the Latinised name of Sir Charles Linné, or Von Linné, the son of a Swedish clergyman, born in 1707. To attempt the analysis of a character so diversified, so distinguished in the varied phases of botanist, natural historian, mineralogist, and doctor of medicine, would be impossible; sufficient for our purpose to briefly outline the career of this remarkable man, whose great mental attainments were second only to his untiring application to work, and work carried out in the most methodical manner. The circumstances of his birth may account for that innate love of nature so early developed, the simple charms of the Swedish pastor's garden and the necessitous seclusion in which they lived accounting for that, but the manner in which he went onward and upward to the highest pinnacle of fame a young student could possibly aspire to, marks him as a man of phenomenal mental endowments.

At the age of twenty young Linné left home to enter the university of Lund, and reaped the advantage of being kindly received by Dr. Stolæus, a physician and naturalist. A year after found our hero anxious to pursue his studies in the wider field afforded at Upsala, and here the first pinch of poverty was felt, his father with difficulty being only able to allow him £8 sterling towards this course of his education. Early struggles were to him but the incentive to self-advancement, and he quickly rose to the occasion by gaining a Royal scholarship, and further enhanced his means by private tuition. Recognition could not be denied a man who so early asserted his right to it, and under more favourable circumstances he now commenced the writing and arrangement of those exhaustive works, which, so far as botany is concerned, may, to some extent, have been displaced by simpler methods, but will never fail to excite and command the admiration of all scholars.

One visit only was paid by the learned Swede to England, where some little jealousy seems to have detracted from its pleasure; but by this time his botanical fame had spread through the whole of Europe, although it was not confined to that science alone, for every branch of natural history engaged the attention of this wonderful man.

His early excursions, chiefly on foot, extending over 10 degrees of latitude, and reaching within the arctic circle, are speaking witnesses of that indomitable energy which even privation and hardship were powerless to abate, and the mind of the man is still further shown in that indefatigable zeal which led him into a practical study and examination of the mines of his country, the results of which were no sooner acquired than to be again disseminated in his teachings. We also find him at this time taking out his degree as a doctor of physic (he eventually obtained the post of physician to the Fleet). As well as from his own Sovereign the reputation of Linnæus procured for him honours from all the chief centres of learning in Europe, and at his death in 1778 a general mourning took place at Upsala, whilst the same generous monarch, in his speech from the throne at the State's Assembly, lamented the loss Sweden had sustained in the death of her gifted son.

In the endeavour now to form a just estimate of the character of Linnæus, the impression obtains that his nationality is veiled under his vast labours and manifold accomplishments; that his gifts were for all people, as the results of them will probably endure for all time. His library and herbarium are now in possession of the Linnæan Society of London. To do justice to the memory of a great countryman of our own, whose labours were, perhaps, more in accord with our own work of gardening, and also to include a brief sketch of those eminent French and German scholars who have done a lion's share in scientific horticulture, we may well occupy another short paper.—INVICTA.

(To be concluded.)

FIBROUS ROOTED BEGONIAS.

AT one time these useful Begonias were largely grown for winter flowering. Fashion then changed the order of things, and for several years they almost dropped out of cultivation, only, however, to reappear again in another form of gardening. Some of the varieties were found to be well suited for summer bedding. For this purpose their good qualities were quickly recognised by many, and they now rank among the most popular of summer bedding plants. In this way a great impetus has been given to their culture, with the result that hybridists again turned their attention to them, and have now given us a race of very dwarf varieties extremely useful for planting as edgings to flower beds or borders.

In January last I sowed seeds of Sutton's Miniature, Fairy Queen, Duchess of York, and Reading Snowflake. The plants resulting from these sowings I found of great service in pots throughout the month of May, as they supplied just the kind of material required for use in conjunction with Fern in forming edgings to jardinières, vases, or bowls in carrying out house decorations. I have also several beds of them in the flower garden which are already beginning to make a good display. I have, however, reserved some for growing in pots for autumn flowering. These will be shifted at once into 5-inch pots, have the flowers removed, and be grown in pits throughout the summer, and I look forward to securing a fine batch of dwarf flowering plants of a type none too plentiful during the autumn and early winter months. Now that fibrous Begonias are generally recognised as being good summer bedding plants many cultivators are again growing some of the varieties largely for winter flowering, as they see clearly that on account of their wonderful floriferousness they are well able to hold their own against many modern plants much grown for the same purpose.

Those on the look out for a new feature in winter flowering

plants would do well to make a start at the present time with some of the best varieties of these Begonias. Young plants ready for potting may be obtained very cheaply, and frames or pits recently cleared of bedding plants are just the places to grow them in during the summer months.

I find a simple yet fairly rich compost suits them well. The one I use consists of three parts loam, one leaf soil, and one of well decayed manure, with a little sand and artificial manure added. Although it is a good plan to keep the plants close for a time after being repotted, it is not wise to coddle them afterwards. They ought to be given abundance of air—in fact, such treatment as tuberous Begonias enjoy during the summer; but during autumn and winter their flowering capabilities are not fully demonstrated if kept in a lower temperature than one ranging between 50° and 60°.

The following varieties are some of the very best:—

Argyrostigma gigantea is a strong grower, with large foliage beautifully marked with silver spots. Ascotensis is a grand bloomer, which bears large clusters of pink flowers. Carrieri is fine for winter flowering, flowers white. Fuchsioides is well adapted for covering walls and pillars, and in a suitable temperature flowers freely throughout the year. Attractive pot plants, suitable for decorative purposes, may be had in flower in the depth of winter.

Hybrida floribunda is a grand free-flowering hybrid, bearing coral-coloured flowers. It is one of the few plants which possess the distinction of blooming profusely throughout the year without becoming exhausted; this, too, when grown in comparatively small pots. Hydrocotylifolia is good for winter flowering; the foliage is bronzy. Insignis is free and vigorous; the flowers are of a lilac-pink colour. Knowsleyana is one of the very best for winter flowering; colour light blush.

Nitida is a very strong grower, which produces large clusters of silvery blush flowers in both winter and spring. Nitida alba odorata is similar to the preceding, except in the colour of the flowers, which, as the name implies, are white.

Ricinifolia is a useful variety, having large bronzy green leaves and bold flower stems. Semperflorens gigantea rosea and semperflorens Dr. Chassagny are a pair that should be grown by all for winter flowering, as they are very free and showy. Gloire de Sceaux, a recent introduction, is certainly one of the most beautiful winter-flowering Begonias we have. It is upright in habit of growth, and the soft pink flowers stand well above the bronzy foliage. Those who only require one variety should grow this, which concludes my list.—H. D.

PRECEPT AND PRACTICE.

(*Continued from page* 500, *last vol.*)

THE SCIENCES GENERALLY CONSIDERED.

A GENERAL knowledge of those sciences which are in intimate relationship to gardening must be regarded as essential—indispensable; although such knowledge from its complexity and vast extent will not, probably cannot, in the aggregate extend beyond sound elementary principles except in that direction towards which the individual bias inclines it.

One matter previously touched may now be concluded—viz., natural propagation other than by seeds, for this in a measure enters into our daily practice in some shape or form. What Nature pure and simple does, and can do in this direction, will only briefly detain, although her methods are both interesting and ingenious to supply auxiliary means of perpetuation. The branch depending to the ground—a natural method of layering; root buds; suckers; bulbs, corms, and tuberous roots of all kinds, with their plenary powers of reproduction and multiplication independent of seeds. Such methods, of course, being practically excluded from annuals or biennials, which we find generally endowed with marvellous fecundity of seed-bearing powers. There is here a fine field for observation and experimenting.

Respecting our own work of propagation and the practices of budding, grafting, and inarching, whereby the sturdy wildling or vigorous variety supports and nourishes the finer bred relation, such work must ever present an attractive interest to the young horticulturist, and it is a matter for regret that many are debarred from practising the theories they may be well versed in. Here we find a nursery training conferring privileges which may be excluded from the general routine of a private garden. Some of the most delightful of early days are recalled by memories of budding—Rose budding and fruit tree budding. Two of us, boys, carried the worsted and tied in after the budders, who were, of course, experts, and kept us rigorously to our own share of the business, but the dinner hour was our opportunity, when we inserted buds to our heart's content into every available branch or plant, from a Thorn to a Thistle, and took many surreptitious peeps afterwards at our (un)handiwork.

Since, as a head gardener, I have (and doubtless many of the same status have too) observed a good deal of this boyish practice carried out much on the same lines and in the same stealthy manner—buds and grafts where no buds and grafts should be. But early recollections are accompanied by a good deal of sympathy for those who, having the will, will find the way to amalgamate precept with practice. Our lads of the bothy, whose work does not include anything in the way of budding or grafting, can, if they will, bring these matters into the category of their pleasures, and if the "head" should be startled at finding a Victoria Plum or a Général Jacqueminot Rose springing from the hedgerow it may be overlooked in the knowledge that "boys will be boys," and that the culprit in particular will be a gardener. With many matters, as with these, we may now and again hear the lament that an opportunity has been wanting, with the poor attempt at self-satisfying consolation that it may never be needed. There is no balm in the whole kingdom of gardening for this sore, and if our young readers can conscientiously say that they have no opportunity, and granted that such is a fact, and granted, too, that they want it, then would I say, Create your opportunity, and you will have it.—AN OLD BOY.

(To be continued.)

NON-PRODUCTIVE STRAWBERRIES.

THE remarks that are now being made about Strawberry plants are extremely interesting, and I will relate my experience with them. When Royal Sovereign first came out I sent for six plants. Four of these bore some splendid berries the first season after planting; while two of them, the finest of all, did not even blossom. I propagated a large bed from all the runners I could get, and, being a novice, used all the six plants for that purpose. That accounted, I suppose, for the large number of barren plants in the bed and in another I have made since. Laxton's Noble, under exactly similar circumstances, gave the same result.

In order to settle the matter once for all—to my own satisfaction, at least—I am this season making more accurate experiments. The plants, both fertile and barren, are isolated, so that there will be no danger of taking a wrong runner, as there always is in a large bed. I have noticed, too, that in old plants there are several crowns, of which some are barren and some fertile, and it is difficult to avoid making a mistake with the runners. It is a good plan to pull out in May all the plants and parts of plants that do not blossom.

I am working with Royal Sovereign, Laxton's Latest of All, and Sir J. Paxton; but on a bed of Auguste Nicaise I cannot find a barren plant for experiment. If others will undertake the same interesting work we shall be able to say by this time next year, without the present uncertainty, what percentage of Strawberry plants comes right and wrong from fertile crowns, and what percentage comes wrong and right from barren crowns. Also, if the plants are allowed to stay in their places for a second year, we shall know whether the barren ones become fertile by age.—T. W. B.

THE ROSE ACACIA.

ROBINIA HISPIDA, or, as it is often called, "The Rose Acacia," is a native of the South United States, and makes a valuable addition to any collection of hardy shrubs. Possibly on account of its not being really well known it is rarely met with, except in those places where shrubs are made a speciality of. At Kew several masses are to be found.

The plants grow to a height of 6 or 8 feet, and all the young wood is thickly clothed with reddish brown hairs, which vary in length up to one-third of an inch. As the wood becomes older many of the hairs turn woody and sharp. The pinnate leaves are made up of from eleven to seventeen leaflets, which are ovate in shape, and terminated with a long stiff hair. The flowers vary in colour on different plants from almost white to deep rose. They are produced on slightly drooping racemes four or five together. On the typical plant the flowers are about the size of an ordinary garden Pea, rose coloured, with the side petals of a lighter shade, the calyx, like the young wood, being thickly covered with soft brown hairs.

Of the several varieties that known as Robinia hispida var. inermis is the best. The wood of this is glabrous, the flowers larger, and produced in larger racemes. The growth is not so free as in the type, but it makes much the better plant of the two for a single specimen. When grafted on a short stem small round-headed trees are formed.

To propagate the typical plant the long roots should be cut up into pieces 3 inches in length, the pieces being put singly in thumb pots in sandy loamy soil, and kept in a close case until growth and root action has commenced. In case of the variety mentioned it may be grafted on stocks of R. pseud-acacia, or the young growths may be layered. Between propagating and planting permanently not more than one or two years should pass, as very long roots with little fibre are made, consequently large plants do not move well. Sandy loam with yearly dressings of farmyard manure suits it well.—D. K.

ROSE SHOW FIXTURES FOR 1897.

July 2nd (Friday).—Crystal Palace (N.R.S.).
,, 6th (Tuesday).—Diss.
,, 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, Leeds,† and Tunbridge Wells.
,, 8th (Thursday).—Bath, Bedford, Farningham, Gloucester, Harrow, Newcastle-on-Tyne,† and Woodbridge.
,, 10th (Saturday).—Manchester, New Brighton.
,, 13th (Tuesday).—Wolverhampton.†
,, 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
,, 22nd (Thursday).—Halifax and Trentham, Bedale.
,, 23rd (Friday).—Ulverstone.
,, 27th (Tuesday).—Tibshelf.
,, 28th (Wednesday).—Chester.*
,, 31st (Saturday).—Liverpool.*

* Shows lasting two days. † Shows lasting three days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list any further fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

ROSE JUDGING—"THE NATURE OF THE BEAST."

IT must be now several years since I put this question in Rose judging before the readers of the *Journal*—Are we to make any allowance for "the nature of the beast" or not? It originally came up at the Crystal Palace. A triplet of Jules Finger (T.) was before the judicial eyes of my fellow judge and myself; the blooms were *passée* in colour and not a pleasing sight. When I expressed my condemnation my coadjutor excused them with the words, "Oh! that is the nature of the beast." That was true enough, but the point was that I did not see there was any reason why the beast should not be condemned for his evil nature.

On Thursday last, when I was judging with a very well-known amateur, whose knowledge of the manners and customs of H.P.'s is second to none, the same point came up again. He would judge each Rose by its *own* standard, instead of by one chosen or ideal one. Thus, perhaps, for instance, while we were pointing the blooms:—"Oh!" said he, "that is Ulrich Brunner; it is not big enough for Ulrich." "But," said I, "we have nothing to do with that; so long as it is in size up to our chosen standard it may be worthy of our highest points, whatever variety it is." "Still," said he, "as Ulrich Brunner it is undersized, and therefore loses points." I did not agree with him, but considered our chosen three-point Rose to be the ideal standard for three points, in size as well as other matters.

It seems to me that a *reductio ad absurdum* may easily be made of my friend's arguments. By his contention Wm. Allen Richardson, or Perle d'Or for the matter of that, may be big enough, if not undersized for the variety. We cannot give them this credit; nor, I imagine, can we detract from the value of a naturally large Rose, if it is large enough for the standard. I shall be glad if rosarians, especially if members of the N R S Committee, will talk this matter over together.—W. R. RAILLEM.

CARNATION SUPPORTS.

"I HAVE a 'patent' method of supporting the flowers of Carnations, and am wishful to make the readers of the Journal a handsome present of it. It is not a 'Jubilee patent,' but merely a device of the very simplest kind which I have adopted for a long time, and which saves endless trouble, for it does away with the old-fashioned and very tedious process of tying. It is simply to take a Willow rod and cut it into the lengths required, sharpen the bottom of each stick by a single cut of the knife, then take the other end and split it open; into this split the flower stem is placed, and is held firm and safe, the other end of the support being, of course, forced into the ground. Nothing could be simpler."

[Thus writes an esteemed correspondent; but in view of what we have to say his name is not published, or his friends might perhaps, in humourous mood, add another. The simple method described so clearly is not a "Jubilee patent," and though it has been in use to our knowledge for thirty years, it may not be the less an invention of our correspondent; and while we have seen hundreds of the home-made supports used, we do not know in how many gardens, they may not be known to numbers of Carnation growers, to whom the hint may be useful. The neatest method of securing Carnations is by the sticks and wire clips used by Mr. R. Sydenham and other growers, and though cheap enough and extensively employed a supply cannot be had by all who might like them for supporting their flowers, and to them the "handsome present" of our correspondent may be useful as a Jubilee gift at Carnation time.]

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL, JUNE 29TH.

THE Drill Hall on the above date presented a very bright and beautiful appearance. Almost the whole of the available space was fully occupied with exhibits appertaining to the Floral Committee. Fruits and vegetables were less numerous. The most conspicuous Orchid exhibit was the silver Flora medal one of Messrs. J. Veitch & Sons, Ltd., which contained many superb flowers. The Rose show held in conjunction will be found reported on another page.

FRUIT COMMITTEE.—Present: J. Cheal, Esq. (in the chair); with Messrs. A. F. Barron, J. H. Veitch, A. Dean, J. A. Laing, G. H. Sage, G. Wythes, H. Balderson, J. Smith, W. H. Divers, G. Norman, and R. Fife.

Mr. G. Kelf, gardener to Mrs. Abbott, South Villa, Regent's Park, sent three boxes of Peaches, including Royal George, Dymond, and Dr. Hogg. The fruits were well coloured, and a credit to the grower. Strawberries from Messrs. Laxton Bros., Bedford, were splendid. The varieties comprised Monarch, Leader, Commodore, Profit, Alma, and Mentmore. The same firm sent a new early Pea named Thomas Laxton.

Mr. J. Hudson, gardener to Leopold de Rothschild, Esq., staged Plums Jefferson, Kirke's, Transparent Gage, and Reine Claude de Comte Attherns, together with Cherries Black Circassian and Bigarreau Napoleon, all the fruits being in first-rate condition. Mr. E. Beckett, gardener to Lord Aldenham, Aldenham House, Elstree, sent Pea Carter's Early Morn, a handsome podded early variety. Messrs. Kelway and Son, Langport, sent an unnamed Longpod Bean and a dish of Peas.

Melons were sent by Mr. A. Bishop, gardener to Dr. L. Burrell, Bury St. Edmunds; Mr. W. Davies, gardener to the Hon. H. E. Butler, Nidd Hall, Yorks; and Mr. C. Martin, Clarence House Gardens, East Cowes, but no award was made.

Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, sent Melon Thames Bank and fruiting branches of the Loquat.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, H. B. May, R. Dean, G. Stevens, J. Hudson, J. F. McLeod, C. J. Salter, R. M. Hogg, J. Fraser, W. Bain, J. W. Barr, C. E. Pearson, C. E. Shea, H. J. Jones, H. J. Cutbush, E. Beckett, C. Blick, and H. Turner.

On each side of the entrance to the Hall Messrs. J. Veitch & Sons, Ltd., Chelsea, arranged a semicircular group of Conifers. None of the specimens was of course large, but the quality was splendid. There were well known as well as rare species and varieties, attracting a considerable amount of attention. The same firm also staged a collection of Sweet Peas, comprising all the leading varieties (gold medal). Messrs. W. Cutbush & Son, Highgate, staged a large group of Malmaison and border Carnations in fine condition (silver Flora medal). Hardy flowers in extensive variety came from Messrs. J. Cheal & Sons, Crawley. There were Violas, Poppies, Potentillas, and many others (silver Banksian medal).

Messrs. Barr & Son, King Street, Covent Garden, sent a large collection of hardy flowers, amongst which the most noticeable were Delphiniums, Potentillas, Calliopsis, Iris Kæmpferi, Campanulas, Hemerocallis, and Phloxes (silver Banksian medal). The hardy flowers from Mr. M. Pritchard's, Christchurch, Hants, were in considerable variety, and of high quality (silver Banksian medal). The small group of Roses staged by Mr. G. Baskett, gardener to Lord Penzance, Eashing Park, Godalming, comprised both single and double forms. Four boxes of Roses came from Mr. W. Rumsey, Waltham Cross. The most conspicuous variety was the new Mrs. Rumsey, with its lovely soft pink flowers (silver Banksian medal).

Very bright was the exhibit from Messrs. Kelway & Son, Langport. It contained Delphiniums, Cannas, Gaillardias, Iris Kæmpferi, and others (silver Banksian medal). Mr. H. B. May, Upper Edmonton, arranged a handsome collection of Adiantums in extensive variety (silver-gilt Banksian medal). Begonias, both single and double, from Messrs. H. Cannell & Sons, Swanley, were of good quality, and contained several varieties of more than average merit (silver Banksian medal). Pansies, Violas, and Sweet Peas comprised the exhibit of Messrs. Dobbie & Co., Rothesay. The sprays of Violas made a very effective display alone, the Sweet Peas losing in effectiveness through being rather packed in the receptacles (silver Flora medal).

The plants of Malmaison Carnations from Mr. J. F. McLeod, gardener to J. P Morgan, Esq., Dover House, Roehampton, were superb. The foliage was stout and perfectly free from disease, while the flowers were large, richly coloured, and delightfully fragrant (silver-gilt Flora medal). Messrs. W. Paul & Son, Waltham Cross, sent an interesting collection of Roses both in pots and cut. There were several varieties that have been introduced by this firm during the Victorian era, besides others that are very rarely seen (silver Banksian medal).

Messrs. R. Wallace & Co., Colchester, sent hardy flowers of splendid quality. Liliums, Irises, and Calochorti, with Hemerocallis aurantiaca major, were very conspicuous (silver Flora medal). Mr. Foster, Brockhampton Nurseries, Havant, staged a collection of Sweet Peas in variety (silver Banksian medal). P. Purnell, Esq., Woodlands, Streatham, sent a small group of Carnations; and Mr. W. Wells, Earlswood, a few Chrysanthemums.

One of the handsomest exhibits in the Hall was that of Messrs. F. Sander & Co., St. Albans. The group comprised splendidly grown plants of Anthuriums, Watsonia Ardernei, Nephrolepis bostoniensis, Caladium albanense, Streptocarpuses, Encephalartos gracilis, together

with a few Orchids of great merit (silver-gilt Banksian medal). Messrs. J. Veitch & Sons sent baskets of Indigofera decora alba, Escallonia Phillipiana, Cytisus nigricans, Robinia hispida, Diervilla sessilifolia, and Calycanthus lævigatus, together with a box of Rhododendron javanico-jasminiflorum hybrids.

CERTIFICATES AND AWARDS OF MERIT.

Adiantum fasciculatum (H. B. May).—A graceful form, with rather thin, tall-growing fronds (first-class certificate).

Begonia Lady Pearson (J. Laing & Sons).—A beautiful double variety, with pure scarlet flowers (award of merit).

Calochortus clavatus (R. Wallace & Co. and C. J. Van Tubergen, jun.).—A very beautiful flower, the colour is rich yellow (award of merit).

Carnation Haidee (C. Blick). — A fine deep heliotrope coloured variety, of splendid substance (award of merit).

Carnation Hampden (C. Blick.)—A lovely rosy buff variety, with medium sized flowers (award of merit).

Cypripedium Mrs. E. V. Lowe (H. Low & Co.).—A chastely coloured form with white petals spotted with crimson. The dorsal sepal is green at the base, spotted brown, and with a broad white margin. The pouch is pale greenish white (award of merit).

Lælio-Cattleya Eudora superba (J. Veitch & Sons).—This is a form that is in all respects an improvement on the type. The colour is superb (first-class certificate).

Pink Albino (J. Lamb).—A fragrant white variety, with smooth petals (an award of merit).

Rose Kaiserin Augusta Victoria (Paul & Son).—This Rose is now too well known to need any description (award of merit).

Rose Madame A. Chatenay (Paul & Son).—A lovely Hybrid Tea. The colour is pale salmon rose flushed with very pale buff (award of merit).

Rose Marquise Litta (W. Paul & Son).—A fine rich rose coloured Hybrid Tea (award of merit).

Rose Souvenir de President Carnot (Paul & Son).—A superb Hybrid Tea, with blooms of beautiful shape. The colour is very delicate rosy white (award of merit).

Strawberry Mentmore (Laxton Bros.).—A handsome Strawberry, resulting from a cross between Noble and British Queen. The colour is very deep and the flavour fair (award of merit).

Thuia gigantea aurea (J. Veitch & Sons).—A superb golden formed variety of the well-known type (first-class certificate).

FRUIT CROPS IN IRELAND.

THE very sharp weather we had during the months of April and May left the prospect of a good fruit crop in this part of Ireland far from good. Apricots except where protected are a failure ; Pears, Cherries and Plums a light crop, Morello Cherries especially. Apples on walls have set well, Ribston Pippins carrying a heavy crop. In the open Pear and Plum trees have very few fruits on them, some having none, although all flowered abundantly. Damsons are a complete failure, Apples are irregular, some trees being heavily laden, and others having very few fruits on them. Outside Figs are a heavy crop, and very early.

Small fruits, with the exception of Gooseberries, are a very heavy crop. I never saw Strawberries and Raspberries so promising, the rain for the past three weeks having done them much good ; the berries of the Strawberry are very large on account of it. Royal Sovereign, Noble, and John Ruskin were ripe the same time (June 16th) on a south border, Leader a few days later. Others which do well and will ripen in the order named are Sensation, Lord Suffield, Empress of India, Auguste Nicaise, Monarch, President, Bothwell Bank, Sir J. Paxton, Dr. Hogg, Scarlet Queen, and Latest of All. The last named is only in flower (June 20th) in the open border. It grows strongly and produces runners freely, though several complaints have been heard about it in those respects.

Currants are a heavy crop, the bunches being extra long. Gooseberries are a light crop in most gardens. Under glass all fruits look promising. —W. T., *Tullamore*.

A VISIT TO SUTTON'S.

ARRIVING at Reading on the eve of the Royal Counties Agricultural Show, and being too late to secure a comfortable bed, I naturally did not feel inclined to linger on the couch in the smoking room any longer than necessary, so having performed my toilette set out to visit Messrs. Sutton's nurseries by way of a constitutional previous to visiting the show.

One of the first things that attracted my attention was the magnificent show of Gloxinias, which were grandly flowered, and which do the firm so much credit. A very beautiful variety is the pure white Her Majesty. Duke and Duchess of York and Sutton's Purple are grand varieties, and stand out very distinctly in a collection. The "French" strain of spotted varieties has been much improved by this firm, and many novelties of sterling merit are to be seen.

But I must also say a few words about the Begonias, Streptocarpus, and Calceolarias. Begonias are very largely grown, long ranges of houses and frames are filled by thousands of plants looking in the best possible condition. The flowering houses contained many charming varieties of doubles and singles, of erect dwarf habit, and sturdy growth. The double named varieties were certainly amongst the finest I have seen. The single varieties were scarcely so forward, but those commencing to flower clearly prove that they were first rate. Streptocarpus were grandly flowered and in good variety ; the blues, lilacs and reds prove that it is a strain of excellence, the curious Streptocarpus Wendlandi being quite at home, and I think will prove wonderfully useful for grouping purposes.

Calceolarias are very largely grown for seed. The strain contains many beautiful colours, and is very dwarf, compact, and of strong constitution. Cloth of Gold interspersed amongst them had a telling effect. I did not see one poor variety. Time fails me to enlarge upon what I saw at Messrs. Sutton's, but I will warrant anyone who contemplates a visit that he will be quite satisfied that he has used the time to good account.—H. PBOSSER, *The Knoll Gardens, Wimborne*.

HOYA BELLA.

ONE of the most charming little plants for the stove is Hoya bella. It is a diminutive and delicate counterpart of the well-known Hoya

FIG. 1.—HOYA BELLA.

carnosa, and like its equally pretty relative, H. Paxtoni, is much better suited than the old species for a shelf near the glass in the stove, as they are both dwarf and compact in habit, with small umbels of flowers. These two species have long been great favourites with me, as they produce a charming display of flowers, and I find they are, when well grown, invariably admired. Similar treatment suits them both—namely, a compost of peat, sand, and finely broken charcoal, the pots being thoroughly drained. A warm position is required where the plants can be fully exposed to the light, otherwise they are liable to become sickly and unsatisfactory.

H. bella (fig. 1) has been in cultivation many years, and might be expected to be in almost every collection of plants ; but such is by no means the case, for I know many gardens of more than ordinary pretensions where it is not grown, and why this should be I entirely fail to understand. This neglect of a beautiful plant is strange, for when its delicate wax-like white flowers with their rich purple central rays are fully expanded the plant is unrivalled except by its near relative, H. Paxtoni. The neat trusses of flowers are invaluable for cutting when something particularly choice is required.—R. THOMSON.

Notes & Gleanings

EVENTS OF THE WEEK.—The shows that are to be held during the coming week are very numerous, and Roses will be in evidence in all parts of the country. Rosarians will be most interested in the N.R.S. Metropolitan Show at the Crystal Palace on Friday, which promises to be of much excellence. Other fixtures will be found in the list on page 4.

—— WEATHER IN LONDON.—The Diamond Jubilee celebrations were, as all the world now knows, carried out in what is recognised as Queen's weather. On Thursday evening a thunderstorm passed over London, being much heavier in some parts than in others. Friday and Saturday were fine again, while on Sunday morning rain fell heavily for about two hours, the afternoon and evening being fine. Small rain was in the wind on Monday morning, but the afternoon was clear. Slight showers fell in the evening, and again on Tuesday morning. Wednesday was fine.

—— GARDENING APPOINTMENT.—Mr. John Ricketts, late foreman to Miss Gretton, Bladon House Gardens, Burton-on-Trent, has been appointed head gardener to J. P. Jackson, Esq., Stubben Edge Gardens, Ashover, near Chesterfield.

—— NEWCASTLE SUMMER FLOWER SHOW.—This Show will be held in the Recreation Ground on Thursday, Friday, and Saturday, 8th, 9th, and 10th July. Very valuable prizes are offered for Roses, including a special Victorian prize, and for table decorations and bouquets. To nurserymen who put up stands not for competition the Society offer their gold, silver, and bronze medals. Besides bands the Society have been fortunate in obtaining the Army Gymnastic Staff to give displays each afternon and evening.

—— EMPLOYÉS' ANNUAL EXCURSION.—The weather was all that could be desired on Monday last, when the employés of Messrs. John Sharpe & Son, of the Royal Seed Establishment, Bardney, took their departure by the nine o'clock train en route for Sutton-on-Sea, where they had been kindly invited by Mr. W. H. Sharpe to spend the day, accompanied by the "Bardney Brass Band," which is upheld by the firm, who added greatly to the day's pleasure by playing lively airs in grand style at interva's. On arrival at Sutton the party had a splendid dinner, after which the Vicar, who accompanied the party, in a short speech proposed the health of the firm, which was drunk with great enthusiasm. A march was then made to the beach, where cricket, donkey riding, and other seaside pastimes were indulged in freely, enjoyment being the order of the day, no expense being spared by the firm to add to the enjoyment. Tea was provided at four o'clock, after which the party returned to Bardney, after having spent the happiest day that anyone could wish for.

—— TO REGULATE THE SALE OF FRUIT.—Reform is in sight in the marketing of fresh fruits in Chicago so far as size of package and quality are concerned. A new city ordinance is now in force which covers the situation quite fully. It is substantially as follows: It is against the new law to offer for sale any basket, box, barrel, or other package of fruit or vegetables which is not of uniform quality and size throughout. Packages of Peaches, Apples, Quinces, Potatoes, Pears, Berries, Plums, Beans, Onions, Peas and all other kinds of fruit, except Grapes and Bananas, shall contain quarts, pecks or bushels and multiples of same, and the entire contents in each package must be distinctly marked on the outside. Section 2 of the ordinance says: All Grapes which shall be sold in any basket, box, or other package or parcel containing a definite quantity shall be sold in one pound or multiples thereof, and the quantity in each and every package shall be distinctly marked on each package so that the same can be easily read by the purchaser. It remains to be seen whether this means in actual practice that the Grape shippers of New York, Ohio and Michigan must put exactly 9 lbs. in a 9 lb. basket, and so mark the outside. The penalty section of the law provides that whoever sells any package which does not run uniform in quality throughout or is short in weight or measure shall upon conviction be fined from 10 dols. to 25 dols. for each offence. Coloured netting cannot be used over baskets of Peaches and Grapes.—("American Agriculturist.")

—— PROPOSED NEW PUBLIC GARDENS.—Prizes have been offered for the best designs for laying out public pleasure grounds at Yeovil (Somerset) and at Crediton (Devon). At Yeovil there were nine competitors. In both cases the first prize has been awarded to Messrs. R. Veitch & Son, Exeter, for designs prepared by their landscape gardener, Mr. F. W. Meyer.

—— CHRYSANTHEMUMS MRS. AIRDRIE AND DUCHESS OF FIFE.—Will anyone who has grown these two varieties give their opinion as to their similarity? I believe they are the same, although no one seems to have made any remark upon them. Have any of the special classification committee grown the two varieties? If so, they must have noticed they were the same in habit, foliage, size of flower, and colour. Intending exhibitors must be careful about staging the two varieties as distinct.—W. WELLS.

—— ROBERT HOGG MEMORIAL MEDAL.—At a meeting of some leading horticulturists held at the Horticultural Club on Tuesday, the 15th ult., it was determined that a die for a medal in memory of the late Dr. Robert Hogg should be cast and presented to the Royal Horticultural Society, who will from time to time issue a medal for fruit to be called the "Robert Hogg Memorial Medal." A committee was formed, of which Mr. Harry J. Veitch consented to be the Chairman, and Mr. Harrison Weir kindly undertook to make a design for the obverse of the medal. Subscriptions will be solicited to defray the expense, not to exceed 1 guinea, while smaller subscriptions will be asked for. A circular will shortly be issued, and in the meantime any person wishing to join may send their subscriptions either to Mr. Veitch or to the Rev. H. H. Dombrain.

—— OUR HOLIDAY NUMBER.—Just as everything had to stand aside last week in London for the great Royal procession and not soon-to-be-forgotten Diamond Jubilee celebration, so had what may be termed the usual work-a-day contributions to this Journal, and even the reports of some shows, for matter of a different kind. We took care that no inconvenience was caused to inquirers on subjects of urgency, as they were answered by post. We are glad to know that the change of literary fare for the week proved so universally acceptable, and though we cannot publish several commendatory letters we have received on the subject, we thank the writers of them all the same. Mr. Arnott desires to say that he is "unfortunately" not (as some readers seem to have assumed he was) the author of the matter preceding "Balmoral," intimating at the same time that he would like to know the writers, and to see Mr. D'Ombrain.

—— JUBILEE POETRY.—We have had numbers of verses sent to us of one kind or another relative to the above event, the best being the following from "Sixty Years a Queen," by Mr. W. Baylor Hartland, Cork:—

"All London put by toil to-day—
Old Sol came forth with pride;
The rich, the poor, 'neath buntings gay,
Were marshalled side by side.
Refrains of music filled the air,
Caught up by hosts unseen—
The same old song—the same old prayer—
That prayer!—God save the Queen!!!"

The lines have the merit of conveying truth. It is a bold thing to prophesy as to what "Old Sol will do" (for the lines were written some time before June 22nd); but it is a fact that the sun "came forth" exactly at 11.15, the time of departure of the Queen at Buckingham Palace.

—— NOTES FROM THE ISLE OF WIGHT.—The thirteenth annual Rose Show and Exhibition of cut blooms was held in connection with the Ryde Horticultural and Exhibitions Association on Tuesday, June 15th. The Exhibition was opened by the Mayor of Ryde, who stated that the entries were not so numerous as in previous years, which was accounted for by the lateness of the season. The day was beautifully fine and the attendance very large, over £40 being taken at the gates. The principal prizewinners were Messrs. F. Cant, J. O. Brook, T. L. Winthrop, B. Ladhams, Mrs. E. C. Murray, Mrs. Morritt, Miss G. Carter, and the Rev. J. Shearme. Splendid collections of wild flowers were staged by Mrs. C. Kent, Miss L. Kent, and Mr. V. Kent, over 150 varieties being in the first prize stand. Mr. B. Ladhams of Shirley staged a magnificent collection of hardy perennials, which were greatly admired. The Isle of Wight Rose Society held its exhibition on Friday, June 18th, in conjunction with the National Rose Show at Portsmouth. Many of the usual exhibitors in the Island were conspicuous by their absence.—S. H.

CORNUS KOUSIA.

It cannot be said ("M. G. R.") that this shrub is very frequently seen, notwithstanding its great beauty. The leaves, which are oval in shape and rich green in colour, are luxuriant and attractive, while the pure white Trillium-like flowers are certain to elicit admiration. C. Kousia is figured and described by Siebold in his "Flora Japonica," I., page 30, t. 16, under the name of Benthamia japonica. The genus Benthamia has long since been very properly merged into Cornus, and the present name may have in some measure obscured its origin. According to Siebold it is a dense bushy shrub about the height of a man, growing wild on the mountains of Kinsin and Nippon in Japan, from 2000 to 4000 feet elevation, flowering in May and June. Its affinity with the Himalayan Cornus (Benthamia) fragifera is very manifest. Bushes such as those described above as growing in Japan could not have otherwise than a picturesque effect when clothed with the pearly white flowers as shown in our illustration (fig. 2, page 9). We believe Messrs. J. Veitch & Sons were the introducers of this plant.

HORTICULTURAL SHOWS.

YORK.—June 16th, 17th, and 18th.

The thirty-ninth annual show of the above Society was held in the Bootham Asylum Grounds. The show of this year will be long remembered hy the Gala Committee and the exhibitors, as the experience of the opening day was unique in the history of this Society, and it is to be hoped in all other kindred societies. With the barometer gradually falling the day previous, and rain early in the morning of the 16th, it was feared the opening day would he a wet one. Instead of rain, however, a strong gale sprang up, and with disastrous results. The whole of the vast marquees in which the exhibits were placed, covering it is estimated about 3 acres of ground, were blown down, the poles snapped in twain, and the canvas in many places was torn into rihbons. By two o'clock the gale had completed its terrible havoc. The one containing the fruit and table decorations was the first to go. Some of the exhibitors got their fruit out, but much would he spoilt. The tent in which the valuable collections of Orchids were staged was the next to go, many of the plants being overturned and hroken; the tents now left forming three sides of a square, these soon sharing the same fate. The one in which the groups were arranged presented the most lamentahle scene, the short poles being lifted from the ground and dashed against the plants, sending them in all directions. The tent containing the specimen stove and greenhouse plants stood the test the longest. Most of the large and valuahle specimens were safely transferred to the vans. The usual gathering of membhers of the Committee, Judges, and invited guests had to be ahandoned.

Of the many good shows held, this promised to be one of the best. It will be remembered that last year the Committee of the Royal Horticultural Society visited the show. No doubt this brought a larger number of exhibitors, especially from the trade. It was thought that it might not be so good this year. The schedule, however, contained several new classes, and had the weather been favourable, this would no doubt have proved the best show ever held in the Cathedral City. The groups were arranged on each side of the entrance tent, leaving an opening up the centre, from which the large cone of specimen stove and greenhouse plants in the next tent could be seen. There were only five exhibitors in this class. The arrangement of the groups was quite up to their usual standard of excellence. At no other show are the groups arranged to produce so good effect as they are at York.

Messrs. J. Cypher and Mr. W. Vause, Leamington, were the only exhibitors in the class for ten stove or greenhouse plants in hloom and six ornamental fine-foliage or variegated plants. Two good groups of Carnations in pots were set up by Messrs. Laing & Mather, and Messrs. W. Cuthush and Son. One of the principal features of the show was a class for a collection of Orchids in bloom arranged for effect, occupying space not exceeding 150 square feet, Palms, Ferns, and foliage plants being allowed, for which a first prize of £20 and the Society's gold medal was offered, given to commemorate the sixtieth year of the reign of H M. the Queen. There were many valuable plants in these collections, Messrs. J. Cypher and Mr. John Rohson, Bowdon Nurseries, Altrincham, being the exhibitors. There were several other classes for Orchids, for which substantial prizes were offered. The Show Pelargoniums were a grand sight, good specimens and better flowered than some years. Collections of Roses in pots were good. The exhihitors in this class were Messrs. W. Jackson & Co., Mr. G. Cottam, and Mr. H. Pyhus. The cut Roses were not quite so good as last year, and the number of entries less.

A new class was for a decorated table of ripe fruit, not to exceed fourteen dishes and not less than ten dishes, plants in pots allowed, flowers and foliage to be in glass epergnes, prizes of £15, £12, £8, and £5 were offered. Sir J. W. Pease, Bart., M.P., the Duke of St. Albans, the Earl of Harrington, and Mr. Jas. Sinclair were the exhibitors. There were classes for six kinds of fruit and four kinds respectively—in all fourteen classes for fruit. Prizes as usual were offered hy Messrs. Sutton & Sons and Messrs. Wehh & Sons for collections of vegetahles, which brought several competitors.

The gale commenced its work of destruction just before the time for judging, so of course no prizes were awarded. It was hinted that the show would be closed; hut a meeting of the Committee was held under the presidency of the Lord Mayor, and it was resolved that the exhibits should he removed, hut that the Gala, so far as possihle, should proceed, the admission to the field heing reduced to half price, as no flower show could be held. The loss wlll be heavy both to the Committee and the exhihitors. It is to be hoped it will not prevent the latter from staging at future shows.

PORTSMOUTH.—June 18th.

In the Victoria Park, which is most conveniently situated to the railway station, the annual Southern Provincial Exhibition of the National Rose Society was held, and considering the backward state of Roses was of much excellence. If the hlooms generally were not large, they were exceptionally clean, shapely, and bright in colour, combining the salient qualities of the flower. The garden Roses were no douht the feature of the Show, demonstrating so ahly the value they possess for floral decoration. The variety, too, of form and colour in this section is most charming, from the pure single Sweet Briar to the compact and neat button-like blossoms so freely displayed. The Isle of Wight Rose Society held its meeting in conjunction with the parent Society, an arrangement that seemed to be quite a happy combination, as hoth apparently benefited hy the association. The arrangements were of the best, under the ahle guidance of the Hon. Secretaries, the Rev. H. H. D'Omhrain and Mr. E. Mawley. Captain Ramsay, Fareham, the Hon. Secretary to the Local Committee, exerted himself to make the Show what it was—a success.

The centre of interest lay in the principal class for forty-eight distinct varieties, one truss of each. Mr. B. R. Cant was some distance ahead of his three opponents, securing the coveted award with medium-sized handsome blooms, heautifully staged. Especially worthy of mention were Madame Gabriel Luizet, Ulrich Brunner, Marchioness of Downshire, Marie Baumann, Captain Hayward, and Kaiserin Augusta Victoria. With smaller, yet bright, blooms Messrs. D. Prior & Sons, Colchester, secured the second award. The third prize was taken hy Mr. G. Mount, Canterbury. In this class Messrs. F. Cant & Co., Colchester, were unfortunately disqualified through including a sport from Susanne Marie Rodocanachi, not yet in commerce, and thus contrary to rule 7, which is a recently added one.

Although the entries in the class for twenty-four distinct varieties were limited to three, they made a pleasing display. The post of honour was occupied hy Messrs. Curtis, Sanford & Co., Torquay, with medium-sized, richly coloured examples of popular varieties. The second prize was secured by Messrs. Burrell & Co., Cambridge; Mr. G. Prince winning third place. Five exhibitors ventured for the prizes in the class for triplets, in twenty-four varieties. Mr. B. Cant followed up his previous success hy easily winning from Messrs. Curtis, Sanford & Co. the premier award with a really fine stand of shapely specimens. Messrs. D. Prior & Sons were third.

Tea and Noisette varieties were well staged. Mr. G. Prince, Oxford, won first honour in the class for twenty-four distinct single trusses. The hlooms were even, clean, and tastefully set up. Golden Gate, Comtesse de Nadaillac, The Bride, alha rosea, Cleopatra, Innocente Pirola, and Maréchal Niel were noticeable for their excellent quality. Messrs. D. Prior & Sons and Messrs. F. Cant & Co. were second and third respectively. Mr. John Mattock, New Headington, Oxford, won for one dozen single trusses with creditable examples. Messrs. Curtis, Sanford & Co. second; Messrs. G. Cooling & Sons, Bath, third. For twelve blooms, any one H.P., Messrs. Prior & Son, with Lady Mary Fitzwilliam, easily took the winning card. For Mrs. Sharman Crawford Mr. B. Cant was awarded second prize; Messrs. Curtis, Sanford and Co. third.

Interest centred in the amateurs' division in the class for twelve distinct single trusses, the first prize being the "Ramsay" cup, value 10 guineas, given hy Captain Ramsay. Mr. Mease, gardener to Alfred Tate, Esq., Downside, Leatherhead, won easily with heautiful hlooms, including Madame Watteville, Ruhens, Caroline Kuster, Hon. E. Gifford, and Jeanie Dickson. Mr. R. E. West, Reigate, was second. For two dozen blooms, distinct, there was but one entry—Rev. J. H. Pemherton, Havering. This, however, was so thoroughly deserving that the first prize was awarded. Mr. R. E. West, with neat highly coloured blossoms, secured the leading award for eighteen distinct; Mr. F. W. Campion, Reigate, second. Mr. West in the triplets, six varieties, again was distinguished by having the premier award made in his favour. Mr. Campion and the Rev. J. H. Pemherton were equal second.

For the "Prince" Memorial cup there was keen competition, eighteen distinct hlooms heing the number required. A. Hill Gray, Esq., Bath, secured this coveted award with medium size hlooms, clean and good. Mr. Campion was again second. Dr. Seaton, Bitterne, won for six distinct; Mr. West second; Miss G. Carter, Ryde, third.

The competition in the open classes was hrisk. Five staged twelve distinct triplets. Mr. Prince was first with commendahle examples, Mr. B. Cant second. Mr. Prince was also successful for twelve any variety Tea or Noisette, with handsome examples of Princess of Wales.

Garden Roses made a magnificent display. For thirty-six distinct varieties, open to nurserymen, three competed. Messrs. G. Cooling and Sons, Bath, were an easy first with one of the hest exhibits ever seen. Not only were the varieties wisely chosen, hut their arrangement left little to be desired. Messrs. Paul & Son, Cheshunt, were second with a commendable collection, and Mr. C. Turner, Slough, third. For nurserymen another class was made for eighteen bunches. Here the leading

award fell to Messrs. F. Cant & Co. with a grand collection. Mr. J. Mattock was an exceedingly close second.

Amateurs contributed worthily to this part of the exhibition. For eighteen bunches, distinct varieties, Mr. Mease was easily first with a grand display; Mr. A. Chandler, Haslemere, second. Rev. J. H. Pemberton staged a really fine collection in the class for twelve bunches. For six bunches Mr. Campion won easily. Silver medals were awarded for the best Tea or Noisette in both sections, a like award being made for H.P.'s. In the amateurs' section Mr. Mease secured both with superb blooms of Madame de Watteville and Mrs. J. Laing. Mr. Prince with Comtesse de Nadaillac secured a like award for the champion bloom in the Tea or Noisette section.

In conjunction with the N.R.S. the Isle of Wight Rose Society held their annual exhibition, which was most satisfactory to both societies. The blooms staged by exhibitors for this Society's prizes were distinctly creditable. The principal prizewinners were the Rev. Dr. Morgan, Wootton; Rev. J. Spittal, Ryde; Mrs. E. Croft Murray, Ryde; Mrs. J. O. Brook, Ryde; and Lady Mary Gordon, Shorwell. Mrs. S. Marshall, Southsea, took first prize in the three classes devoted to table decorations, epergne of Roses, and a vase or bowl of Roses. In all classes the exhibits possessed much merit. Mr. B. Ladhams, Shirley, Southampton, staged a fine collection of hardy herbaceous plants, as also did Mr. Pritchard, Christchurch.

A few particulars respecting the show held by the National Rose Society at Portsmouth on the 18th inst. may be of interest, as it took place at an earlier date than any previous exhibition of the Society. The total number of blooms staged in competition was 1660, or a smaller number than at any other N.R.S. show yet held. In this calculation no account is taken of the beautiful display of garden Roses at this or previous shows. There were in all thirty-seven exhibitors, who came from the following counties:—Devon, Dorset, Somerset, Hants (including the Isle of Wight), Kent, Surrey, Essex, Bucks, Herts, Oxford, and Cambridge. Owing to the coolness of the previous night and the stormy character of the exhibition day the blooms stood remarkably well, and were, as a rule, as fresh late in the afternoon as when staged in the morning.—E. M., *Berkhamsted*.

RICHMOND.—JUNE 23RD.

ON the above date, in the well-known Old Deer Park, the Richmond Horticultural Society held its annual Show. As was expected, it was not up to several of its predecessors, the competition in some of the classes being very poor. However, quality was not lacking in any particular department, though some of the Roses and cut flowers would have been better away. We were glad to see that the Committee had provided a small tent for the sale of fruits and flowers in aid of the funds of the Gardeners' Royal Benevolent Institution, and we trust it would prove a great success. Where such a course is possible it would be a graceful act on the part of societies to provide similar accommodation to swell the Fund which benefits the needy ones amongst their supporters. Some splendid fruit and flowers were kindly given by Andrew Pears, Esq, J.P., as well as by several exhibitors. We mention below the prizewinners in a few of the classes.

The classes for Roses were not particularly numerous, but the flowers staged were, all things taken into consideration, highly creditable. In the classes for forty-eight and twenty-four trebles, respectively, the premier awards were taken by Mr. B. R. Cant, Colchester, who showed in his well known style. Several of the flowers were of superb quality. Messrs. D. Prior & Son, Colchester, were second in each case. For twelve trebles Messrs. G. Prince, Oxford, B. R. Cant, and D. Prior & Son were the successful competitors in the order named.

Mr. B. R. Cant was a splendid first for twelve of any one H.P. with Mrs. J. Laing; Messrs. D. Prior & Son being second; and Dr. Budd, Bath, third. For twelve Teas, Messrs. D. Prior & Son were first with Souvenir de S. A. Prince; Mr. G. Prince, with Comtesse de Nadaillac in beautiful form, being second.

In the amateurs' class for twenty-four single trusses Dr. Budd was first; P. Burnand, Esq., Reigate, second; and R. E. West, Esq., Reigate, third, each showing some good blooms. Dr. Budd was again first for twelve distinct, followed by Mr. C. Warwick, gardener to J. P. Kitchen, Esq., Hampton; and P. Burnand, Esq. In the remainder of the Rose classes quality was not particularly conspicuous.

Mr. W. Farr, gardener to A. Pears, Esq., Isleworth, staged handsomely in the class for six exotic Ferns. His plants showed splendid culture. Mr. C. Want, gardener to Sir F. Wigan, East Sheen, was second; and Mr. T. Smith, gardener to W. H. Odlin, Esq., Isleworth, third. Mr. Charles Turner, Royal Nurseries, Slough, was the only exhibitor of six Show and Decorative Pelargoniums, receiving the first prize; as also did he for six Fancy Pelargoniums. Mr. G. Watts, gardener to H. Little, Esq., Twickenham, was to the front with six Ivy-leaf varieties and for six Zonals. In each of these classes high quality was very conspicuous.

Mr. H. E. Fordham, the Nurseries, Twickenham, was an easy first for a group of flowering and foliage plants arranged for effect in a space not exceeding 100 square feet. The arrangement of Orchids, Gloxinias, Liliums, Gypsophila, Hydrangeas, and Carnations, with Ferns, Caladiums, and Palms was superb. Mr. Gibson, gardener to E. H. Watts, Esq., Chiswick, was second, and Mr. W. Vause, Leamington, third. For a smaller group Mr. C. Want was first, and Mr. J. Portbury, Putney Heath, second.

The last named exhibitor was to the front with a group of Begonias, followed by Mr. Johnson, gardener to D. H. Scott, Esq., The Old Palace, Richmond. Specimen plants, both flowering and foliage, were well shown by Messrs. W. Vause, C. Want, and W. Farr. Mr. C. Howard, gardener to H. Little, Esq., Twickenham, was first for six Orchids in bloom, with splendid specimens, followed by Mr. W. H. Young, Orchid grower to Sir F. Wigan.

Fruits and vegetables were shown in considerable numbers, and were, as a whole, of excellent quality. In the vegetable section for Messrs. Sutton & Sons' prizes, Messrs. C. J. Waite, J. Gibson, and J. Smith staged in excellent form Peas, Potatoes, and Cauliflowers, each being conspicuously good. Messrs. C. J. Waite and J. Gibson staged with the same splendid quality in Messrs. J. Carter & Co.'s classes. For fruit the most successful contributors were Messrs. W. Ford, gardener to W. H. Ellis, Esq., Hounslow; W. Tidy, gardener to W. D'Arcy, Esq., Stanmore Hall; T. Osman, Chertsey; C. Want; J. Grey, Bodorgan, North Wales; H. Blake, gardener to the Earl of Onslow, Clandon Park, Guildford; G. Parker, Isleworth; J. Goody, Twickenham; and Mr. A. Menton, gardener to J. B. Hilditch, Esq., Richmond. Grapes and Strawberries were particularly well shown.

Miscellaneous exhibits were of excellent quality, and staged in considerable numbers; indeed, had it not been for these the tents would have looked thin in many places. Both nurserymen and private gardeners contributed. Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, arranged a semicircular group, including well-grown plants of Liliums, Ixoras, Cattleyas, Odontoglossums, Aërides, Cymbidiums, Hydrangeas, Palms, Caladiums, Crotons, Ferns, and Nepenthes. Mr. W. H. Holah, nurseryman, Richmond, had an effective exhibit of miscellaneous flowering and foliage plants, amongst which half-standard Fuchsias were conspicuous. Messrs. J. Peed & Sons, Norwood, had a charming exhibit of Carnations, and Messrs. W. Fromow & Son, Chiswick, one of such plants as Palms, Asparagus, Crotons, Ferns, Acers, Gloxinias, and Ferns. Messrs. W. Cutbush & Sons, Highgate, sent Malmaison Carnations of good quality, and Mr. H. E. Fordham, Twickenham, had a beautiful group of Gloxinias, amongst which Gypsophila and Ferns were intermingled.

The group of Begonias from Messrs. J. Laing & Sons, Forest Hill, contained plants of excellent quality admirably arranged; and the same may be said of the Malmaison Carnations of Mr. J. F. McLeod, gardener to J. Morgan, Esq., Dover House, Roehampton.

Messrs. J. Carter & Co., High Holborn, had an exhibit very similar to the one staged by them at the Temple Show, and it again attracted attention. Mr. W. Thompson, nurseryman, Richmond, sent a number of plants, including Liliums, Spiræas, Caladiums, Crotons, and Ferns; while Mr. Pentrey, gardener to A. J. Howard, Esq., Isleworth, sent Carnations. The Agri-Horticultural Association sent an exhibit of vegetables and plants.

CRYSTAL PALACE.—JUNE 23RD AND 24TH.

IN commemoration of the great event of the week provision was made by the directors of the Crystal Palace for a Victorian era flower show in their noble building on the dates above named. A sum of £350 was placed at the disposal of the Judges to allocate in twenty-six classes, subject to the exhibits being meritorious. Some of the prizes were very good indeed, and none of them such as to discourage competition. It was not through any shortcomings in that direction that so many of the classes were not filled nor the space set apart occupied, but simply because the show could only under the circumstances be little more than local.

When this show was announced it was felt by many persons to be a bold venture, considering the great strain imposed on so many gardeners and nurserymen in preparation for the rejoicings of the day preceding, yet the Orchids exhibited found their way from the north of London, Pelargoniums and Roses from Slough, a grand assortment of Coniferæ from the Coombe Wood Nurseries of Messrs. J. Veitch & Sons, Ltd., Cannas from Cheshunt and Swanley, and the most meritorious cut flowers of hardy herbaceous plants from Colchester.

To take, as indicative of the slackness, the first two classes in the schedule, though we find six prizes offered for tuberous Begonias, the highest £12 and the aggregate amount £29, only a solitary collection was staged—an imposing one, it is true, and containing splendid varieties, but there was nothing to which the five other prizes could be awarded. Yet though there was such a lack of competition, with no entries at all in some of the classes, and practically illimitable space, still the tables of cut flowers were so densely packed and crowded as to produce very much of a jumble.

As it would be of no particular interest to go through the schedule and enumerate the prizewinners in the stereotyped way, it must suffice to say that Messrs. John Peed & Sons were the only exhibitors of Caladiums and Gloxinias, securing first prizes. W. C. Walker, Esq. (Mr. G. Cragg, gardener), Winchmore Hill, N., the only amateur exhibitor of Orchids, a charming first prize collection; Messrs. Lewis & Co., Southgate, being equally alone in the nurserymen's class with a good first prize group. Mr. Turner was also alone in his glory with Show and Fancy Pelargoniums and Roses, for which he was adjudged the prizes.

In the hardy herbaceous cut flower classes Messrs. Wallace & Co. Colchester, outdistanced all competitors with an extremely beautiful collection of Liliums, Spanish Irises, and translucent Mariposa Lilies (Calochorti), than which it is difficult to imagine any flowers more beautiful in vases. Messrs. Paul & Son, Cheshunt, had the first prize for Cannas, a dwarf bright group; and Messrs. H. Cannell & Sons a

silver medal for a splendid collection; Mr. W. Howe, gardener to Henry Tate, Esq., being adjudged the prizes for Crotons and Ferns.

There were several non-competitive exhibits, notably Messrs. Veitch and Sons' Conifers, one of the finest collections of choice and beautiful kinds ever seen; and quite the finest group of Carnations of the season from Martin R. Smith, Esq. (Mr. C. Blick, gardener), including beautiful new varieties. These two exhibits were the features of the show, and gold medals were worthily awarded for them.

Silver medals were recommended to Mr. R. Gülzow, Melbourne Nurseries, Bexley Heath, for group of Orchids; Messrs. G. Jackman and Son, The Nurseries, Woking, for group of Clematis; Messrs. W. Fromow and Sons, Sutton Court Nurseries, Chiswick, for group of Japanese Maples; Messrs. Young & Co., The Nurseries, Stevenage, for hardy flowers; Mrs. M. Hodgkins, 35, Woodland Road, Upper Norwood, for table decorations; and Mr. Foster, Brockhampton Nurseries, Havant, for Sweet Peas.

Mr. G. Castelton, the new Garden Superintendent, who was most attentive and courteous to all, has thus had a comparatively small show to begin with, because of the trying and entirely abnormal circumstances under which it was held; but there seems no reason why it should not grow into a large one if it should be decided to hold shows in honour of "Victoria Day" in future years.

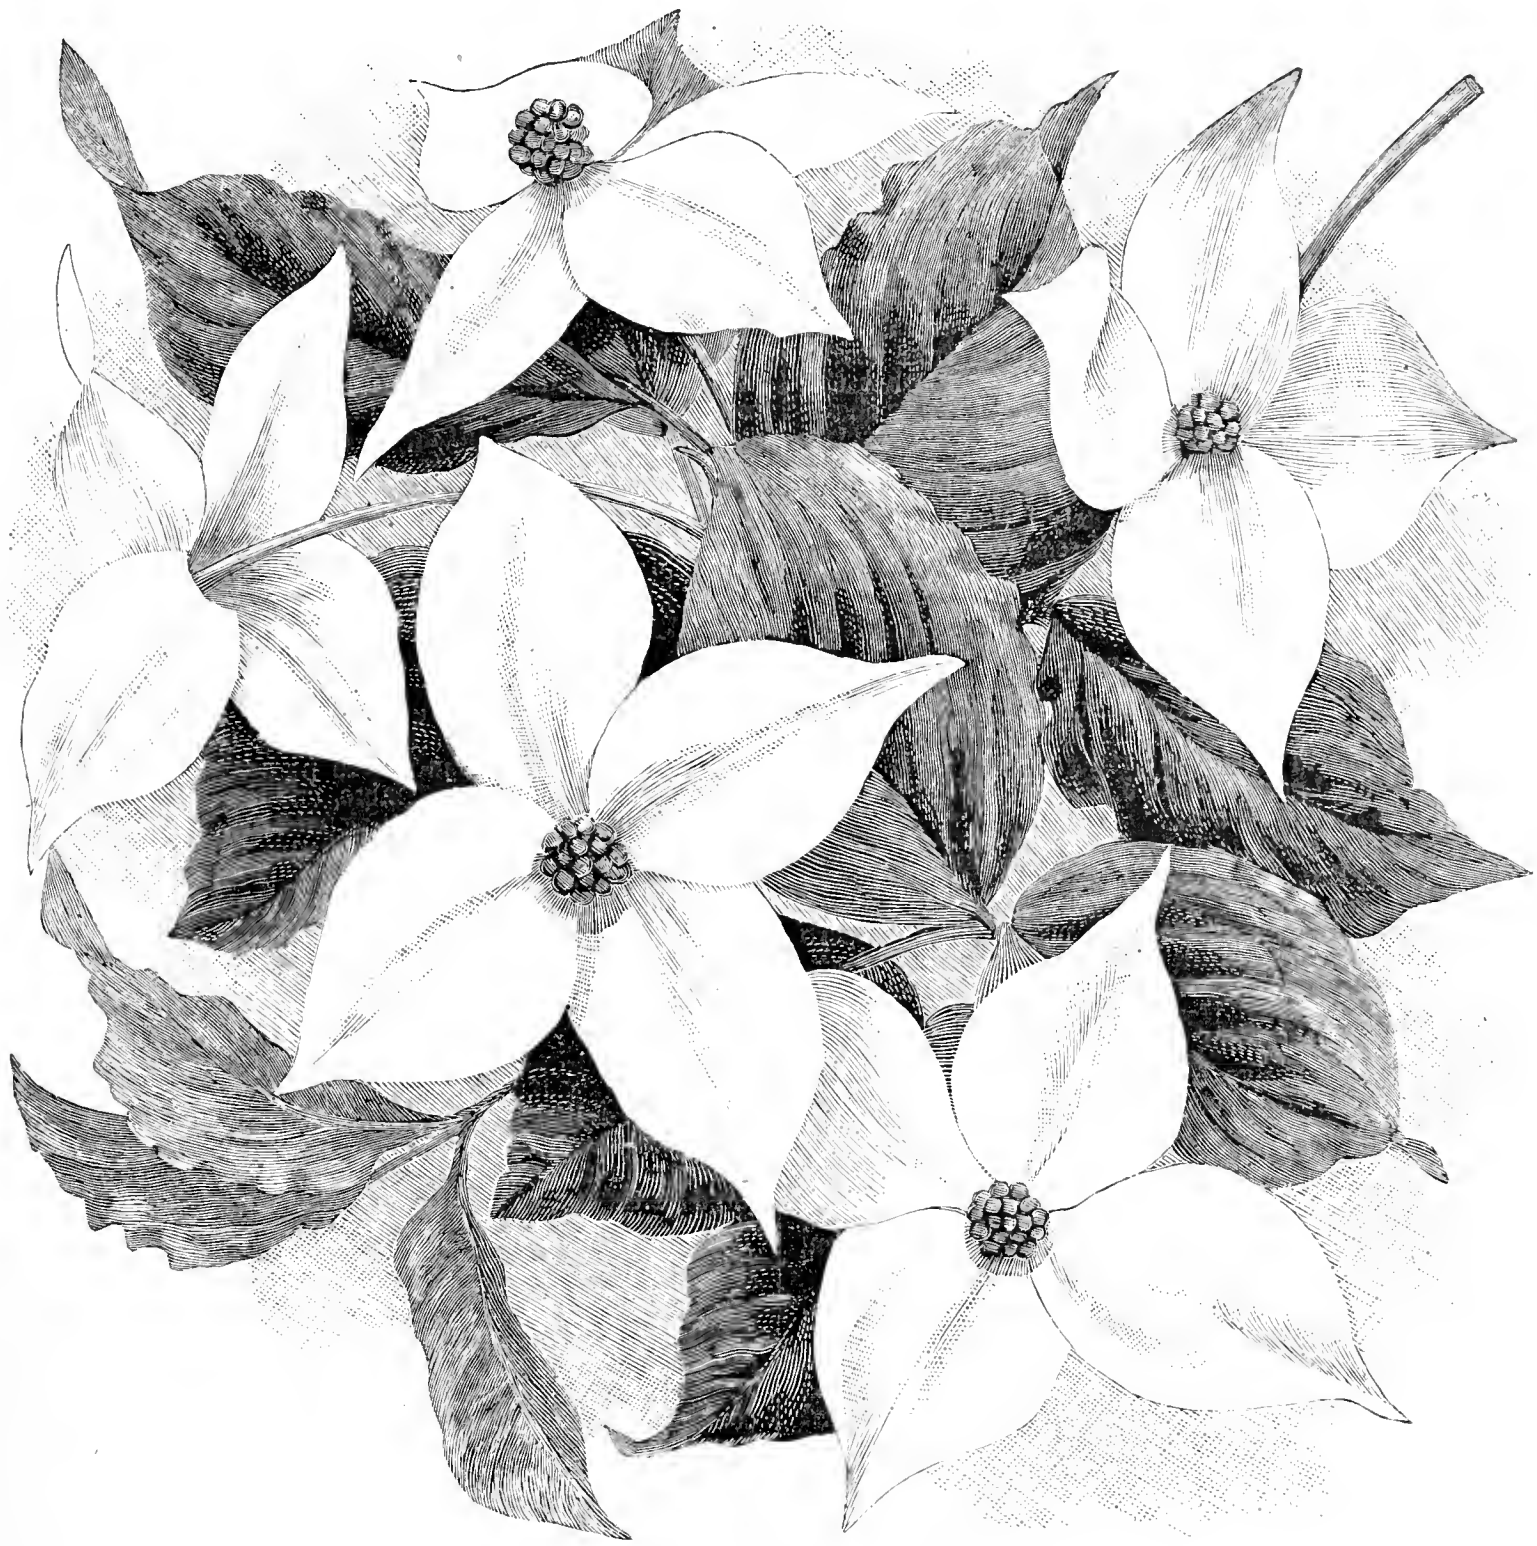

FIG. 2.—CORNUS KOUSIA (*page* 7).

COLCHESTER.—JUNE 24TH.

THE summer show of the Colchester Rose and Horticultural Society was held in the grounds of Mr. C. E. Green, East Hill House. There was a fair amount of competition, and the quality of the blooms staged was good, considering the season. For thirty-six Mr. B. R. Cant was first, his blooms being young and strong, and able to stand the great heat which prevailed. Among his best were La France, Alphonse Soupert, Maréchal Niel, Madame de Watteville, Ernest Metz (finely coloured), and Jean Ducher. Messrs. Harkness were second, Lady Mary Fitzwilliam and White Lady being perhaps the best. Messrs. Prior were third; a very fine specimen of Mrs. John Laing (which easily took the medal over all other Roses in this division), Xavier Olibo, and S. M. Rodocanachi being the best in their box.

In twelve Teas (nurserymen) Mr. B. R. Cant was again first, showing Madame Cusin, Cleopatra, and Anna Olivier well; Messrs. Prince second, with Anna Olivier, Comtesse de Nadaillac, and Souvenir d'un Ami; and Messrs. Prior third, showing Maman Cochet and Marie van Houtte in good condition.

In the amateur classes Mr. R. E. West of Reigate was first for twenty-four, showing a fair specimen of Margaret Dickson; Mr. J. Gurney Fowler second, and Mr. P. Burnand of Reigate third. The standard throughout here was very low. For the Mayor's prize, twelve Roses, Mr. Orpen was first, Kaiserin Augusta Victoria and Madame Hoste being the most noticeable in his stand; Rev. J. H. Pemberton second, winning the medal with a fine example of Caroline Testout; and Mr. Burnand third.

For six Roses of a sort Mr. H. P. Landon was first with Madame Hoste, Rev. A. C. Johnson second with Gustave Piganeau, and Rev. A. Foster-Melliar third with Lady Mary Fitzwilliam. For twelve Teas Mr. Orpen was first, Mr. Foster-Melliar second, and Mr. Berners third, the standard of excellence ruling low. In twelve Roses Mr. A. C. Johnson was first, showing a nice specimen of Gustave Piganeau, and Mr. Page Roberts second. In six Teas Mr. Page Roberts was first, gaining the medal with a grandly shaped specimen of Anna Olivier, without, however, a trace of terra cotta tint, and easily mistakeable for Madame Hoste; H. P. Landon second, and Mr. Johnson third.

In garden Roses Messrs. Prior were first in the nurserymen's class, and Mr. A. C. Green of Great Horkesley second. The latter being apparently a new Rose professional in the Colchester district, it seems as

if the trade were booming, but all were sorry indeed to hear that Mr. Wm. Prior was in bad health, for he is deservedly popular amongst the Rose growing fraternity.

Mr. Orpen was first in the amateurs' class for garden Roses, many well preserved single Roses being a feature in his stand, the Mayor (Mr. H. Egerton Green) second, and Mr. Pemberton third. Mr. Orpen was also first for a collection of single Roses, and it was again remarkable how well the petals stood the heat.

In herbaceous flowers Messrs. Harkness were first and Mr. Jacobi of Ipswich second in the nurserymen's class, Lady North first and Mr. Orpen second among amateurs. Messrs. Wallace showed some samples of their splendid Calochorti and Lilies, a large-flowered yellow Calochortus, called Clavatus, being a new species.

Colchester is now also famous for Asparagus, and great interest was taken in the competition for a cup offered by Mr. Monro of Covent Garden. This was won by Mr. R. T. Daniell of Donyland, and I willingly lingered to hear the comments of experts upon these wonderful great hunches, where (to my ignorant eyes) the premium is given to the handle, and the business end is reduced to small proportions. Two or three men told me the white was the best part; but when asked if they began to eat at the butt end, they rather climbed down from that assertion. Another man said you could eat as far as the pink colour went, and no opinion seemed to be so unpopular as my own, that I did not want to see any colour but green in my Asparagus.

About two o'clock, when the rosarian company had just arrived at the grounds of the noted trade growers, a very heavy thunderstorm, or rather, as it seemed, two or three meeting in one, broke over Colchester. Myland Church spire, within 200 or 300 yards of where several of us were sitting in Mr. B. R. Cant's house, was ripped open from nearly the top to the bottom. Knowing from previous experience what the Rose fields would be like after such a tremendous rain, I rather chose, when the storm was over, to investigate the vagaries of the lightning stroke which, in this case, seemed strangely to have neglected metal in its downward course, and deliberately (what a word for lightning!) chosen stone and wood in perference. Ultimately I thought I would do down and see what the Roses looked like, and soon returned with, as one of the company remarked, enough of the famous soil on my boots to grow a good Marie Baumann.—W. R. RAILLEM.

WESTMINSTER.—JUNE 29TH.

THIS Show was held in the Drill Hall at the usual fortnightly meeting, on the above date. There was competition in each of the classes, and in some of the boxes flowers of superb quality were noticed. With commendable and exceptional generosity C. J. Grahame, Esq., Leatherhead, gave £10 towards the prizes offered.

In the classes for twenty-four distinct single trusses, Mr. C. J. Salter, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, was placed first. His blooms were even, some being of good quality, while others were weak. C. J. Grahame, Esq., in the second position, had a superb stand, containing only one or two weak blooms, with about a dozen perfect ones. The pointing in these two exhibits must have been very close. The Rev. J. H. Pemberton, Havering-atte-Bower, was third. There were five competitors in this class.

Three competitors brought twelve distinct single trusses. O. G. Orpen, Esq., Hillside, West Bergholt, Colchester, was first with Marquis Litta, Horace Vernet, Her Majesty, Gustave Piganeau, Susanne Marie Rodocanachi, Captain Haywood, Madame Eugéne Verdier, K. A. Victoria, Mrs. W. J. Grant, Fisher Holmes, Madame Gabriel Luizet, and Marie Verdier. The Rev. A. Foster-Melliar, Sproughton Rectory, Ipswich, was a fair second; and R. H. Langton, Esq., Raymead, Hendon, third.

For six distinct single trusses, G. W. Cook, Esq., Torrington Park, N., was first; the Rev. A. Page Roberts, Scole, Norfolk, second; and J. Christian, Esq., 3, Norman Villas, Highgate, third. C. J. Grahame, Esq., for nine single trusses, one variety, sent Kaiserin Augusta Victoria in superb form, and received the premier award, followed by Mr. C. J. Salter with Mrs. J. Laing, and the Rev. A. Page Roberts with Madame Gabriel Luizet. Kaiserin Augusta Victoria won for O. G. Orpen, Esq., the first prize for six of one variety. R. H. Langton, Esq., with La France was second; and G. W. Cook, Esq., with Mrs. J. Laing, third.

In the class for twenty-four Teas, distinct, there were four competitors, of whom O. G. Orpen, Esq., was a good first. His flowers were of fine shape, clean, and splendidly coloured. Hardly a weak bloom was to be seen in the box. The second position was secured by C. J. Grahame, Esq.; and the third by Mr. C. J. Salter.

The Rev. Hugh A. Berners, Harkstead Rectory, Ipswich, was first for twelve Teas, with Medea, Catherine Mermet, Ernest Metz, Souvenir de S. A. Prince, Madame Hoste, Edith Gifford, Cleopatra, Comtesse de Nadaillac, Jean Ducher, Anna Ollivier, and The Bride. The Rev. A. Foster-Melliar was a capital second, and the Rev. J. H. Pemberton third.

For six Teas, distinct, the Rev. A. Page Roberts was first, and R. H. Langton, Esq., second. For nine single trusses of one variety C. J. Grahame, Esq., was a decided first, with beautifully coloured examples of Madame Cusin, O. G. Orpen, Esq., with Anna Ollivier was second, and H. P. Machin, Esq., third. R. H. Langton, Esq., with the Hon. Edith Gifford, went to the front for six Teas of one variety, followed by the Rev. A. Foster-Melliar with Souvenir d'Elise, and the Rev. H. A. Berners with Anna Ollivier.

SCHOOL GARDENS.

I WAS pleased to see "A. D.'s" remarks under the above heading on page 511 in your issue of the 10th ult., and will give you an opposite state of things. Here in Birkenhead, a town with over 120,000 inhabitants (about half of whom belong to the labouring classes), I have provided four large pasture fields for allotments, each of which is situated in a different part of the town, and in close proximity to Board and other public schools. The land has been measured, pegged out for allotments, and enclosed with suitable fencing, also gates provided with locks and keys, water service laid down, good cartways and footwalks made, and whatever was necessary for the security and convenience of the allotment holders has been done.

Not a single allotment has been applied for, either by the School Board or the managers of any of the elementary schools, for the purpose of instructing the boys in "Cottage Gardening," but the allotments are freely taken up artisans and others, who are in every way satisfied with their plots.

There are generally two sides to a question, and your readers can now look at this question from both sides. Perhaps "A. D." will tell me where I may get the information respecting the grants he speaks of to schools giving the boys instruction in "Cottage Gardening;" then I will bring the question before the notice of the School Board and managers in Birkenhead, and get their views on the question, and at a future time let you know the results.—T. D. S.

CARNATIONS AT ICKWORTH.

AT Ickworth Park, Bury St. Edmunds, there is just now a very fine display of Carnations, many new varieties and all the cream of the older sorts being well represented. All are conspicuous for fine robust health and freedom from splitting of the calyx, but the newer ones of Mr. Martin Smith's raising stand out as a distinct advance on the older varieties.

A lovely flaked yellow is Mrs. Robert Sydenham, the blossoms large and full, of grand outline and clear cut segments, such as Carnation lovers delight in. Gift has large flowers with a yellow ground, and flaked with light crimson, while a beautiful soft scarlet self is named Isle. Miss Jekyll is an advance on Germania, the habit being all that could be desired, and of splendid constitution.

Cardinal Wolsey is like a greatly improved Atalanta, but judging by the plants not a very good breeder. Mrs. Ivo Bligh and Elsie are two lovely selfs of a delicate salmon rose, the latter the deeper coloured of the two, while blossoms of the purest white are found in the chaste varieties Deal, Mrs. Eric Hambro, and the older Niphetos. Mayma is a distinct fawn self, Vashti a splendid yellow and crimson flake, while Mephisto is of deeper colour and better form than the now well known Uriah Pike. The plants are one and all in excellent order, full of flower, and by their healthy appearance and tasteful arrangement reflect great credit on Mr. K. Coster, the energetic gardener.—DIANTHUS.

BRIEF NOTES ON ALPINE FLOWERS.

(*Continued from page* 439.)

LINUM ALPINUM.

THIS neat little alpine plant, although both pretty and not at all an expensive flower to purchase, is not very often seen; it is still more seldom seen in bloom, which is unfortunate, as its bright blue flowers, large for the size of the plant, are very pleasing. The foliage is also very attractive, so that a plant in full bloom is generally admired. This Alpine Flax appears to like full exposure to the sun, with a good supply of moisture at the roots in summer, but to be comparatively dry in winter. The two last requirements are not easily secured in the same position, and I find it best to plant in gritty soil on a level terrace of a sunny rockery, and to give water rather freely in spring and summer. It seems hardy enough, but its shy blooming qualities in some gardens counterbalance to a great extent its other qualifications.

ARMERIA LAUCHEANA.

This is apparently only a variety of the common Sea Pink or Thrift, which adorns with its thousands of pink blooms many of our sea coasts. It differs from the ordinary form by reason of its dwarfer habit and its deep colouration. No better variety could be selected for contrast with the white variety of A. vulgaris known as alba. If planted on the rockery it is well suited to a variety of positions. On flat terraces it does well, but may also be used for covering up joints between the stones. It is of a deep—almost crimson—colour, and looks well when covered with bloom in June. In this garden it flowers more freely than the white form of the ordinary Thrift. Armeria Laucheana is not difficult to procure from nurseries, and is moderately priced in the catalogues. It is readily increased by division.

ONOSMA ECHIOIDES.

This favourite plant is more commonly known as O. tauricum, a name not likely to be readily superseded by the older name of Linnæus. It is a little difficult to understand why a considerable number seem to fail with it in face of the general advice to give a slight protection from excessive rains in winter. However this may be, many complain of losing it, possibly owing to the want of the precaution mentioned. In some gardens where it has a dry position, sheltered from excessive rains, the safeguard of overhead covering is not even necessary, but nearly all would be wise to be at the little trouble required rather than

run the risk of losing a pretty plant. The rough leaves hold moisture long, and sleet and snow appear very injurious to the plant. Even if shabby looking in early spring it often recovers, and those who think it is beyond recovery may find a week or two of fine weather make a great difference in the look of their plants.

Those who are acquainted with its drooping, almond scented yellow blooms (fig. 3), so distinct from most other flowers of the season by reason of their shape or colour, will not readily be without it in their gardens. A dry soil with full exposure to the sun is to be preferred. It may be increased by cuttings, which root more readily if taken off with a heel of old wood and put in pots of light soil surfaced with sand and placed in a close frame until rooted.

CASSINIA FULVIDA.

The inclusion of shrubs suitable for the rock garden is quite within the scope of these articles, so that no apology is required for speaking of this very distinct-looking plant of shrubby nature. It is occasionally seen under the name of Diplopappus chrysophyllus, but the name at the head of this note is the correct one. If left to itself it becomes rather too large for many rock gardens, but is so amenable to pruning operations that this can hardly be called a fault. It is so readily kept in bounds that a bush several years old may be kept under 2 feet high. It looks very pleasing with its light yellow branches, the same colour also distinguishing the under surface of the leaves, the upper being a dark green. The unopened buds are also yellowish, but the small flowers in flat heads are white. I grow it for the sake of its general aspect, and not for its flowers.

I am not quite certain of its native habitat, but think it comes from New Zealand. It appears hardy in many gardens in England and Scotland, and here has never suffered in my garden from the most severe winters we have had for several years. It is easily propagated by cuttings taken off with a heel and placed in pots.—ALPINUS.

(To be continued.)

GRAPE APPLEY TOWERS.

NEW varieties of Grapes placed in commerce are few as compared with other kinds of fruit, so that when a first-class Grape like the above does appear I am surprised more is not heard of it. In the variety Appley Towers we have a Grape good for market and exhibition. It was awarded, I believe, a first-class certificate by Royal Horticultural Society, and sent out in the spring of 1894 with Lady Hutt, a white Grape of good flavour, but small in bunch and berry.

Appley Towers is a Grape of noble appearance; bunch large, sometimes shouldered, especially on canes which have been inarched on some other variety. This year bunches on a Vine planted in 1894 appear as if they will weigh between 3 lbs. and 4 lbs. each; others inarched two years ago on Black Hamburgh, Golden Queen, and Black Prince are equally fine, especially on the latter. The berries are large, the size of Gros Colman; oval in shape, half way between Madresfield Court and Gros Maroc, not so round as the latter, and borne on stiff footstalks. The colour is an intense black, with a fine grey bloom when finished, like Black Prince.

The fruit hangs well, the berries never losing colour; bunches coloured now (June 20th) will hang till December, but the Grapes are in the best during late autumn. Early in the year they become gritty, but the flavour is very good. Like Gros Colman, Appley Towers will finish a heavy crop of fruit well, so ought to make a good market Grape. The only objection to this is the Vine being such a grower as to require a wide space between the rods, 4½ feet being little enough. Like Alicante in a young stage, the laterals must be tied down carefully, as they are very brittle and easily rolled out of the sockets.—W. T.

THE YOUNG GARDENERS' DOMAIN.

CUCUMBER CULTURE.

ALTHOUGH the Cucumber is classed as a vegetable, it invariably comes under the fruit foreman's charge in large establishments. It is grown in very large quantities in market nurseries, in fact in some of them the Cucumber season is the market grower's harvest. Span-roofed houses are preferred for Cucumbers, for though they do equally well in lean-to houses and frames, the same number of plants cannot be grown in them as in a span-roofed house or pit of equal length and width.

The seed is best sown singly in 3-inch pots, at different periods, according to the time required for the plants to bear fruit. Cover the pots with a piece of glass or paper, and place in a temperature about 75°. When the seedlings appear remove the covering, and afford all necessary light for keeping them sturdy.

The next thing will be to make a hotbed of litter and leaves, treading it firmly. A stake or two may be placed in the bed so that you can tell when the highest temperature is reached. When this point has been passed, and the bed begun to cool down, a layer of turves may be placed on the bed, and upon these small mounds 3 or 4 feet apart. The compost for these mounds should be turfy loam, broken into small lumps, with a little dried cow manure or spent Mushroom bed material added.

When the temperature of the bed has cooled sufficiently to be safe the plants are inserted, and shaded for a few days. Fix a wire trellis to the roof, and train the plants on the top side. By this method the shoots do not require so much tying, and are not dragged out of position by the weight of the fruit. Place the trellis far enough from the glass to prevent the leaves coming in contact with it.

Shading.—Some growers do not shade their plants, but allow them full exposure to the sun from the time they are planted, whilst others shade them rather heavily. I have seen excellent crops of Cucumbers under both methods; but the first is rather dangerous, for if the surface soil, owing to the sun shining on it, becomes dry the plants will flag and the leaves scorch. With the heavy shading system the plants are too long before they fruit, and much time is thus wasted. The practice that I have seen answer the best is to shade the plants very lightly and admit no air, unless on a very hot day, then only a "crack." By this method two crops can be had in the time that one can be obtained by the heavy shading and full ventilating system.

Watering and Syringing.—During the spring and summer months Cucumbers require copious supplies of water, both at the roots and in the atmosphere. Occasional applications of liquid manure are beneficial when the plants are bearing fruit. Some growers add a little soot water, to give the foliage a rich green appearance, but this is not a wise practice, as it is apt to cause the Cucumbers to be bitter. Syringe the plants twice daily—viz, morning and afternoon—getting well under the leaves, so that filth may be kept down. Syringing must be done early in the morning, so that the leaves get dry before the sun has power

FIG. 3.—ONOSMA TAURICUM.

upon them, or it will cause them to scorch. Too dry an atmosphere often causes Cucumbers to come crooked, and to prevent this the paths of the house are damped several times during the day.—ELVEDEN.

(To be continued.)

THE MEANS AND MODES OF PROPAGATING PLANTS.

IN a state of nature all plants, be they what they may, are propagated from seed, and most seeds are covered with a hard shell or envelope, which protects them from external injury, and within that envelope lies the embryo plant. All seeds in this latent state contain an organ or germ, which under favourable circumstances shoots upwards—the plumule—and becomes the stem of the plant; another, called the radicle, seeks its place in the soil, and becomes the root. The seed lobes yield nourishment to the young plant in its first stages of growth.

Moisture, heat, and air are necessary conditions for the development of all growth from seeds, and most of them require in addition concealment from the light. These conditions are found in the open texture of well-pulverised garden soil, through which water percolates freely and air follows, each yielding their quota of oxygen, hydrogen, or carbon in a gaseous state for the support of the plant. Leaves are the first outward sign of germination, and are next to the roots the most important organs of a plant. The seed leaves, as the lobes which first appear above the ground are termed, are of vital importance, and if destroyed prematurely the young plant rarely recovers.

Germination is the natural process by which the embryo of the seed, placed in favourable circumstances, throws off its shell or covering, and in course of time becomes a vegetable, resembling that from which the

seed was obtained. From the time that the acorn of the Oak is placed in circumstances favourable to its germination it absorbs moisture and swells, the root or radicle is elongated, and the shell or envelope is broken. The root issues by the fissure, and directs itself downwards into the earth ; the plumule erects itself, and becomes the stem ; while the cotyledons furnish food to the young plant until the first leaves develop, and the spongioles of the roots are capable of receiving nourishment from the earth. In plants with a soft covering, as the Bean, the radicle is directed to the outside of the seed ; it is the rudiment of the root, and this is the first part which develops itself in germinating. The plumule, on the contrary, ascends towards the centre of the grain and becomes the stem, while the two cotyledons remain in the soil between the root and stem, yielding nourishment to the young plant until the root can perform that office.

Much time is lost by following this mode of propagation, except in the case of annuals. The seed does not always produce a plant identical with the parent. No true double flower produces seeds, and several herbaceous plants with which our gardens are furnished fail to ripen their seeds in our climate. The observation of this led to other methods of multiplying, for besides the roots, properly so called, which attach themselves to the soil and draw from it the principal nourishment of the plant, each branch conceals under its outward covering a bundle of tissue which, under favourable circumstances, develops roots, and becomes the basis of an independent plant identical with that from which it sprang. Many plants have also a crown with buds or eyes, each capable of propagating its species. Every plant with roots of this description may be divided into as many portions as there are eyes, taking care that a few fibres are attached to the root, and each bud thus secured will become an independent plant.—C. W. M.

(To be continued.)

Practice with Science.

Lovers of flowering plants in perusing treatises on their cultivation may frequently come upon a caution to keep the structures in which newly potted plants, or freshly inserted cuttings and offsets, are placed closed for a period. Here we have a subject for a logician. That scientific principles are the foundation of practice we shall try to prove.

Roots are organs, sensitive to heat, cold, touch, exposure, excess or sparseness of supply of building matter, feeling acutely the most delicate help or hindrance to their work. We are convinced of this in considering that by negligence in over or under-watering, feeding, potting, or thoughtlessness in even *one* cultural item we irretrievably lose beauty, and retain only objects for pity.

The sensitiveness to heat by the renewal in spring of growth in tap roots, tubers, rhizomes—which are virtually ennobled roots—demonstrates the fact with these forms. Does not the balmy sweet air of spring, which we then admit to our houses, dispel the drowsy artificially heated atmosphere, and itself seethe around the pots and through the balls of soil, stimulating with new vigour the sleepy plants? When solar heat becomes stronger, growth gyrates almost eagerly, showing the appreciation for heat by the roots and co-builders. Regarding chills and exposure to roots we can comprehend how the functions are hindered, probably destroyed. Robe a man in cold wet garments, and if not actively employed what result do we expect? Debility of body. The food supply and circulation by roots to the stems and leaves is checked by suddenly giving cold water, causing languid and erratic growth. Dryness implies analogous results.

Overfeeding or loading a soil too heavily with nutritive material "sickens" it. It would little matter if indeed it were gorged, provided no roots were there to be "killed by kindness." This is the great evil in overpotting or manuring. The absorption of matter takes place by the process of "osmosis"—viz., the watery fluid with its elements by affinity for the thicker cell contents permeates the outer membrane and cell walls of the radicle or root tip, to act with this cell matter. Now, according to this hypothesis, the roots are unable to stop the supply, even though it be in excess. The flow continues and the cells flush full, are, in fact, choked.

The whole system of the plant is overloaded, like a person who has eaten too well, and whose heart flags under the pressure it must bear. So likewise the plant becomes insipid and flaccid. It can neither exhale or inhale freely, if at all, because of turgidity in the cells, and becomes disagreeably burdened. The chlorophyll and other necessary matter seems rarified, possibly kept too diluted, and being supplied with too acidulous "sap," through the soil being purely acidulous and non-alkaline, it may be poisoned ; and so the plant if uncorrected dies an unnatural death. Summing up, then, like any jury, the conclusions we have drawn, we see how very careful we must be in growing plants artificially to grow them well.

It is to save the strain of a severe check to growth that we keep our structures closed after potting. We allow the leaves and their helpers to work easier while working harder than ordinarily. In the warm air, kept comparatively stationary, the stomates open wide, and breathe deeper and quicker, absorbing liquid and gaseous aids, and freeing the unneeded elements. Rapid evaporation, too, is stopped ; a quiet tone of vitality is insured, and time for the roots to recover and penetrate anew. This with cuttings and offsets is principally applicable, though the other detrimental causes reach them likewise. This article has been written for criticism by "Domain" writers, it having occurred to me how often we do things in practice without reasoning why, or whether it may be proper. If my reasoning be correct it proves the value of science in our practice.—A Young Scot.

HARDY FRUIT GARDEN.

Summer Pruning Fruit Trees.—The summer pruning of restricted trees and bushes ought to be commenced, carrying on the operation at intervals. This method of gradual removal is rational, and guards against the possibility of serious checks being given. Any undesirable shoots, such as those ill placed or weakly, may be cut out entirely, leaving the best and most foreright in position. If the shoots are crowded thin them out. A rank growth of shoots, crowding one into the other, compete for the light available, with the result that many of them grow to an inordinate length for the purpose of reaching the light. Likewise, when undue shade predominates, it proves inimical to those shorter growths originating from the base, and showing a tendency to become fruit buds. Also, a fair share of light and air is prevented reaching the fruit, which retards its development.

Judicious summer pruning, or shortening the longest shoots to a limited number of fully formed leaves at the base, gives at once a check to exuberance of growth, and directs the energies of the trees into the buds and leaves remaining.

Plums and Sweet Cherries.—These fruits are chiefly confined to the restricted form when grown on walls. It is then that summer pruning is most required, so that growths which cannot be laid in are prevented extending and robbing the buds at the base of needful support. The summer shoots are usually pinched when the third largest leaf from the base is fully developed in size. Crowded shoots may be cut out entirely. Further pinching becomes necessary, and should be carried out, when fresh growths have started from the upper bud or buds of the shortened shoots. This ought not to be done, however, before the first formed leaf has attained to a fair size. Subsequent sub-lateral growths treat in the same manner—that is, pinching to one leaf as formed.

Some modification of this system of close pinching can be adopted, chiefly in cases where there are vacant places that require to be furnished. For this purpose select well-placed shoots of vigorous, but not sappy development. Train them in at full length. In the course of the season they, with the exposure to light and air, ripen thoroughly. The following season fruit buds are formed, and probably some of them may be sufficiently matured this season to fruit next. In any case, however, they ought to fruit freely the third season. This method of management is mainly supplemental to a supply of main branches furnished with spurs. The chief object should be to avoid overcrowding, or the bearing capacity of the trees may be jeopardised.

Morello Cherries.—The treatment accorded to these is different. The trees bear the best crops on the one-year-old wood ; therefore, it is best to train in a fair number situated in good positions all over the trees. These shoots require no shortening, simply securing them in the direction wanted. The superfluous shoots—useless, weak, or exhausted portions—must be pruned out as occasion offers. Finally the bearing shoots of the present season should be removed, and the reserved growths for the following year secured in their place.

In some cases Morello Cherries are grown on more restricted forms, the trees having main branches about a foot apart. Spurs have been formed by pinching and stopping foreright and side shoots. Summer pruning must be resorted to with these, stopping the growths it is necessary to restrict at the third leaf, subsequent extensions from the shortened shoot at the first leaf. The buds below will become well nourished, and from them the fruit is produced the next season. Prolific results, however, do not follow this method to the same extent as the former.

Gooseberries.—When Gooseberry bushes are confined to several main branches, and these only allowed to bear the fruit, summer pruning of the side shoots is essential in order to admit light and air to the basal leaves, which perform the functions of nourishing the buds. Shorten these shoots to two pairs of leaves. The leading shoot on each branch may remain without stopping, especially if extension is required.

The more general system of treatment adopted with Gooseberries is simply to thin out the bushes, allowing them to carry plenty of young, well-ripened shoots, which bear freely. This thinning and regulating may be carried out during summer immediately the bushes are cleared of fruit. Attend well to the lower parts and the centres of the bushes, also clear away sappy growths and suckers from the base. The free admission of light and air for the ripening of the wood must be the main point, pruning more fully in winter.

Red and White Currants.—Shorten the side growths from the main branches to the second pair of leaves from the base. The summer pruning of Currants effects two purposes. The fruit is assisted in ripening by the free circulation of air and more exposure to light, and the concentration of vigour in the basal buds.

Black Currants.—Bearing almost exclusively on young wood, summer pruning is only necessary in so far as thinning out crowded shoots and old growths to make room for strong and young wood.

FRUIT FORCING.

Vines.—*Early Vines.*—When the fruit has been cut, syringe the foliage well in order to preserve it as long as possible in a healthy state, for after the leaves fall early second growth not unfrequently sets in when they ought to be resting. A moderate extension of the laterals will usually prevent premature ripening of the foliage, and will not do any harm, but irregularities of growth, and particularly gross ones, should be checked by pinching or be entirely removed. Admit air to the fullest possible extent, and maintain moderate moisture in the border, particularly at the surface, so as to keep the roots there instead of allowing it to become dry, and so causing them to descend in quest of moisture. Weakly Vines may have liquid manure occasionally, which will help them to retain the foliage, and assist in plumping the buds and storing nutritive matter in the adjacent wood.

Grapes Ripening —Afford plenty of air directly the Grapes begin colouring, with a little fire heat to insure a circulation of air constantly and prevent the deposition of moisture on the berries during the night and in dull periods, which is one of the chief causes of "spot." Maintain, however, a fair amount of atmospheric moisture to insure the proper swelling of the berries and the preservation of the foliage in health. Allow the temperature to fall to 65° at night, otherwise securing a temperature by artificial means of 70° to 75°, and 80° to 85° through the day for Black Hamburghs and similar varieties with sun heat. Muscats should have a night temperature of 65° to 70°, 75° to 80° by day from fire heat, and 85° to 90° with sun heat. Supply water or liquid manure thoroughly to the inside borders, enough to reach the drainage, and a light mulching will keep the surface moist. Outside borders must be watered if dry weather prevail, always giving enough water or liquid manure to moisten the soil down to the drainage.

Grapes Stoning.—Ventilate early, so as to allow the moisture to evaporate and the atmosphere to gradually warm in order to avoid scorching, and a gentle warmth in the pipes with a little air constantly is the best safeguard against scalding of the berries. This, with free ventilation by day, and not closing early at this critical period, will usually ward off the moisture that heated on the berries causes them to scorch. As the liability to scald does not extend over a period of more than a fortnight or three weeks, give particular attention in the late stages of stoning to the ventilation. In bright weather succeeding a dull and cold period there is most danger of scorching, and with the modern system of large panes of glass there is absolute necessity at such times for a slight shade from bright sun, especially for Muscat of Alexandria. A double thickness of herring nets over the roof-lights is very beneficial, and affords all the shade required.

Vines Swelling their Crops.—A genial condition of the atmosphere, secured by gentle warmth in the hot-water pipes and sprinkling the paths and borders in the morning and afternoon, particularly the latter at closing time, is essential for the swelling of the berries and health of the foliage. The border being mulched with a little short, rather lumpy stable manure, about an inch thickness sufficing, and this sprinkled occasionally, will give off some ammonia to the atmosphere, and nutriment be washed down to the roots at the waterings. If a little sweetened material be added from time to time, the supply of ammonia vapour and of liquid nourishment will be regular and never so excessive as to injure the foliage. If not convenient to use stable manure the neat drainings of stables or cow houses may be diluted with six times the bulk of water, and this used for sprinkling at closing time, about 3 gallons sufficing for a square rod of border. Avoid a close atmosphere, particularly in dull weather. A little ventilation at the top of the house constantly will make all safe, but it is desirable to close the house in the afternoon, damping well at the same time, allowing the temperature to rise to 90° or 95°, and after six o'clock provide a little ventilation at the top of the house, as it will prevent excessive deposition of moisture through the night. This will to some extent safeguard the foliage against scorching should the sun act powerfully upon the house before the ventilation is increased, which it ought to be as soon as the sun reaches the structure; indeed, it is the best preventive of scorching and scalding. A night temperature of 65°, and a genial warmth of 70° to 75° by day, will be sufficient by artificial means to keep the Grapes steadily progressing in dull weather. Increase the ventilation from 70° to 75°, allowing it to advance to 80° or 85°, and close so as to raise it to 90° or 95°. Permit a steady growth in the laterals, but never allow large extensions which must afterwards be removed or considerably reduced. Do not allow the laterals to interfere with the principal leaves, for upon the free access of light and air depends their elaborating power, and the more these assimilate the crude material the healthier the Vines are, and the more food stored in the Vines for the succeeding crop. It is also essential to the formation of the coming Grapes in embryo in the buds.

Supply sufficient waterings or liquid manure as required, or afford surface dressings, and water them in after having made the border thoroughly moist. Outside borders must not be neglected, but have copious waterings where the rainfall is deficient. Mulch the borders lightly, heavy coatings do more harm than good. A little stable manure, 1 to 1½ inch thick, will lessen evaporation, and from its lumpy nature not deprive the soil of the beneficial action of air, warmth, and the moisture of dew and rain.

Cucumbers.—A few seeds may now be sown for late summer and early autumn produce. The plants from this sowing will afford much finer fruit in late summer than plants that have been in bearing a considerable time, as old plants generally produce knobbed (seeded) fruits towards the end of the season, and are neither so handsome nor useful as straight seedless fruits. The seedlings will be fit to plant in about a month, and succeed admirably in frames with a little bottom heat, such as may be afforded by any partially spent manure, mixed with a little fresh, but not raw, stable litter. It is needless to say that the plants succeed in houses, and give a supply to a late period of the year where there is sufficient heating power.

Plants in Full Bearing.—In order to keep up a regular succession of fruit, attention must be given to thinning exhausted growths, removing bad leaves, stopping, tying, and regulating, so as to keep up a successional growth of bearing wood. Add a little fresh soil to the surface of the bed from time to time with a light mulching of sweetened horse droppings or cow manure, the latter dried and broken up. Syringe at closing time, and maintain a good moisture all day by damping the floors in the morning, noon, and early in the evening. Avoid too much moisture in dull weather, as it makes the growths soft and the foliage more liable to injury on a bright period ensuing. After a few days of dull moist weather it is advisable to shade, and keep the house rather close on the return of bright weather. Supply liquid manure copiously once or twice a week, but it will not materially benefit plants sparsely furnished with roots and defective in foliage. What such plants want is fresh soil or surface dressings of lumpy material. Close early, say at 85°, and advance to 90° or 95°, and only employ fire heat to maintain a night temperature of 60° to 65°.

THE BEE-KEEPER.

SEASONABLE NOTES.

BEE-KEEPERS are close observers of the weather, as it is an important factor in honey production. The cold winds experienced throughout the spring have been the cause of dwindling in many colonies. In some apiaries the majority of the stocks were at least a fortnight later than usual in being supered; but, as the weather has turned out since, it will probably not be detrimental to those stocks that were weak at the end of April if they were headed by young fertile queens. As the weather remained so cold and changeable, supers would have had the effect of lowering the temperature of the brood nest.

The much-needed rain having come, bee-keepers were looking forward to a higher temperature with bright sunshine which would enable the bees to obtain a surplus from the fast opening flowers. On the 12th and 13th ult. it seemed as if their hopes were to be realised, as they were ideal bee days, the temperature being high and the sun shining brightly from an almost cloudless sky. Bees worked with a will as if they intended making up for loss of time. A rapid change, however, came over the scene, for within twenty-four hours a perfect hurricane raged throughout the country, doing a great amount of damage. Large trees were uprooted, roofs and coverings were taken off the hives, and in some instances the latter were overturned. Bees again clustered closely in the body of their hive. In several instances I observed drone brood being turned out of the hive, a sure sign that the bees were taking a gloomy view of the sudden change in the weather. This was followed by a low temperature and rain, the latter doing much good to the growing crops.

The White Clover being now in full bloom, and just at the height of the honey flow, bee-keepers' hopes were nearly at zero when there came a rapid rise in the temperature, and on Jubilee morning the sun burst out in all its glory. It was perfect bee-weather, and raised the hopes of all loyal subjects who in various ways did honour to our beloved Queen in this the sixtieth year of her reign.

The following day was equally fine, a high temperature and bright sunshine prevailing throughout the day. Bees have worked from early morning to late at night. It is only when a high temperature prevails they will collect honey late in the evening. All stocks being now in good condition, honey has been stored at a rapid rate. It is several years since I have seen so much surplus stored in the short space of two days as on this occasion. May it prove a good omen for the remainder of the season.

REARING YOUNG QUEENS.

In our anxiety to obtain as much honey as possible, I fear we are often negligent of queen rearing. Now is the time to rear young queens, for if they are hatched within the next two or three weeks they invariably do well, and as it is a very simple matter to rear and afterwards introduce young queens after they are fertilised there can be no excuse for not carrying out the operation on proper lines.

It may, perhaps, be of interest to state how it is done in my apiary, where if the plan were not successful in providing a hardy race of good workers, which in favourable seasons will store a

handsome surplus of honey, I should not practise it. I always obtain my honey, both extracted and in the comb, from colonies headed by queens hatched the previous year. If they are not crowded to overflowing with bees, when the honey flow comes I add bees and brood from other stocks that are intended for queen rearing. When sufficient colonies are arranged in this manner attention is devoted to queen rearing. This is done from fairly strong colonies, and it is advisable not to destroy the old queens until the required number of young ones are hatched, have become fertilised, and are laying.

When the bees are on the wing in the middle of a fine day is the best time to commence operations. Examine each frame as it is removed until the queen is found, place the frame of brood and all the adhering bees with the queen in an empty hive, and close up with a frame of fully drawn-out combs on each side. If there does not appear to be sufficient bees to cover the brood, shake others into the hive from another comb, place the hive a few yards away from its original stand; now divide the remaining frames and bees into two or three nucleus hives, according to the number of bees remaining, allowing them to stand a couple of feet on either side of the original stand, and young queens will be raised.

Instead of dividing the stock at once after the removal of the queen, it is a good plan to obtain a frame from another stock that has eggs laid within the previous twenty-four hours, cover the whole up warm, and queen cells will be commenced at once. These will be sealed over in about eight days, the young queens appearing on the sixteenth day. Three or four days after the cells are sealed over divide the stock into as many colonies as there are queen cells. If there are not sufficient bees add frames of hatching brood and bees from other stocks. This may be continued until there are young queens enough and to spare. If there are several sealed up queen cells on a comb they may all but one be removed with a knife. Cut out a couple of inches of comb with the cell, which must not be damaged, remove a small piece of comb from the one in which it is to be introduced, and place the queen cell in its natural position, pointing downward, in its place.

If a strong stock should by chance swarm naturally, instead of returning them place them in a hive with fully drawn-out combs or foundation, and if the weather is favourable they will at once store a surplus. A few days afterwards examine the colony from which the swarm came, and form nucleus hives from it, as a dozen or more queen cells will probably be found there, and this is an excellent way of obtaining young queens.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," *8, Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Malmaison Carnation (*W. H. S.*).—The Malmaison bloom you send is a very good one, but we doubt very much whether it is sufficiently distinct from existing varieties to warrant your putting it on the market. Why not send a specimen to Veitch's, or to Mr. Douglas, for their opinion?

Coleuses and Eelworms (*G. P.*).—We presume you have seen the eelworms through a microscope. If you have seen small worms with the naked eye they are not eelworms, and may perhaps be expelled with limewater. For checking eelworms Little's soluble phenyle is very efficacious, but Condy's fluid, which is easier to procure, diluted to a pale rose colour, has been found of great assistance.

Cornus Kousia (*M. G. R.*).—We think you will find the information relative to this plant on page 7 of service. An illustration is given in elucidation of the text.

Soluble Phenyle *versus* **Crude Carbolic Acid** (*W. S.*).—Yes, there is a very important difference between Little's soluble phenyle and crude carbolic acid—namely, the first has the formula C_6H_5, and possesses all the good properties of the latter, but is non-poisonous, soluble to the fullest extent; and while effective as a germicide, eelwormicide, and miticide, acts as a fertiliser. Crude carbolic acid has the formula C_6H_6O—that for the chemist, who says they are the same, is very corrosive, dangerous to handle, as it burns the skin, a powerful poison, only moderately soluble in water, and though an excellent disinfectant where vegetation of a useful kind is not concerned, acts as a plant poison at the time of application, and for a considerable while afterwards, besides not being so effective as an eelwormicide. We have proved these things by carefully conducted experiments, and are satisfied that Little's soluble phenyle is the proper substance to use for preventing and destroying eelworms infesting Cucumbers, Melons and Tomatoes.

Plum Trees Dying Off when Seven to Eight Years Old (*W. S.*)—We have only found two fungoid diseases that cause Plum trees to go off in the manner you describe:—1. A sort of dry canker on the stem similar to that of the Apple tree, but without an excrescence or swelling, the affected part being somewhat shrunken and depressed, due to the destruction of the bark. This is caused by a fungus closely allied to the Apple tree canker fungus (Nectria ditissima), which Mr. Abbey first found on Diamond Plum trees in 1870, and for distinction named Nectria ditissima var. prunaria. Trees affected by it usually die in the spring, as the fungus grows during the autumn and winter, and succeeding in girdling the stem or branch the part above the point infested dies, sometimes without and at others shortly after the leaves come out. 2 A drying up of the bark round the stem or branch, with or without a slight exudation of gum, collapse in this case taking place after the trees come into leaf, and generally in June. It is caused by the brown rot fungus (Monilia fructigena), a very common, but little suspected parasite, and the most malignant to stone fruits in this country. Of course we cannot say what your trees are affected with in the absence of specimens, which should have been sent, but the case appears very like one or other of these mentioned. As for an analysis of the soil, we do not think it would help you materially, as more depends on staple and other cultural matter than can be disclosed by an analysis of the soil. Still it might be useful, but unless taken at more than one depth of soil would, in our opinion, be worse than worthless—that is, money wasted.

Diseased Tomato Fruit (*Tomato*)—The "spot" commencing at the eye of the fruit and extending over the surface so as to form a large depressed blotch, the skin in some being separated from the flesh and giving a sort of scorched or blister-like appearance, has no connection whatever with management, as sometimes asserted, and as you have an example of after giving "every attention, and the fires never been out, warming the pipes every night with ventilation at top and side lights opening into other houses out altogether." The cause solely and absolutely of the "spot" is the growth of the mycelial hyphæ of a fungus in the tissues of the fruit, which descends by the central axis and pushes ramifications into seed receptacles, and destroys all it can penetrate. It is the hyphæ developed from the germ tube of a germinated spore of Diplocladium solani var. tomati, and its ultimate condition Fusarium solani var. tomati. This, however, may be, and commonly is, as regards the fruits, suppressed; but resting spores form in the integuments of some seeds, and these go over with the plant in embryo grow and produce "sleeping disease" in due course. The Diplocladium stage is regarded as saprophytic, but it, all the same, gives rise to "black stripe" and other forms of disease in the fruit, some going so far as to say that it cannot injure sound Tomatoes. All that is mere guesswork, as the fungus pursues its course like any other parasite. It sometimes attacks the fruit during setting and the embryonic fruits turn black. That is said to be non-setting, and its cause damp, moisture having settled on the fructifying organs and destroyed them. In other cases the disease does not appear until the fruit has swelled considerably, sometimes not till near ripening, and the cause in these instances is also regarded as damp—a sort of "scalding." The preventive, therefore, is more air, not only top air but side ventilation, and with that the fruit will not turn black striped or spotted. But though useful it is not always effectual in preventing the spores of the fungus germinating, as vigorous plants will damp in flower and moisture settle at the eye or heel of the fruit, and then it is all over. The fungus will do what it can, and the plant resist to the best of its power, so that the malady may for a time appear arrested, some part of the fruit remaining sound. There is much to be said both ways for this very disastrous complaint, some drowning it and others drying the atmosphere so that it cannot grow. Its very existence depends on organised matter, and to use it moisture must be present. We know no more, except that it has a particular liking for vigorous plants, and that means excess of nitrogen. Water at the roots will wash it (nitrogen) away, and dryness in the atmosphere dissipate the superfluous moisture. Something more rational is needed—namely, an adjustment of the mineral to the nitrogenic elements, so as in the first instance to secure a sturdy plant setting fruit freely and afterwards feed as required. Your soil appears a rich warp, and would be improved by a dressing of basic slag phosphate—say 7 lbs. per rod. There is a fair amount of lime in the soil, evidently added, and could not do other than good. The fungus may have developed from hyphæ pushed by the resting spores in the soil or decayed matter, such as fibre

or vegetable matter in manure. At any rate, the fruits are infested with the mycelial hyphæ of that fungus, and its resting spores will go over with some of seeds, and the plants from them will have "drooping," "sleepy," or "sudden collapse" disease, which ascends, but in your case the fungal hyphæ passes from the eye into the fruit. It is difficult to account for fungi not appearing for years and then becoming malignant. The only thing we can advise is the use of basic slag phosphate, with some mineral superphosphate—say 2 ozs. per square yard, so as to act quickly, getting more lime and phosphoric acid into the plant and fruit, together with side ventilation as well as top, it not being sufficient to have one without the other. If you were to apply a light dressing of some anti-fungoid preparation in powder it would be an advantage, using a bellows apparatus. We sincerely sympathise with you, and very much regret not being able to give better advice.

Hop Leaves Browned (*W. P.*).—The leaves are in bad condition from the attacks of something, but we were unable to discover any insect or remains of any, otherwise the appearance resembles that resulting from an attack of the hop cuckoo fly, frog fly or jumper (Euacanthus interruptus.) Equally unfruitful of result was an examination for fungoid affection. We consider the mischief had been caused by the "jumpers," which have departed on your applying the insecticide Indeed, they are not easy to catch at work, but they are now plentiful on Elm trees, and their sucking must be highly injurious, as wherever they puncture a leaf the spot spreads considerably. The "cuckoos" deposit their eggs on the rootstock, and the young "jumpers" commence feeding on leaves nearest the ground upwards and follow on from the beginning of May, the older leaves appearing the worst, but that is because they show the full effects of the attacks. We found the best thing to prevent attack was lightly spraying over the crowns or stocks with soluble petroleum when growth commenced in the spring, following it up at about fortnightly intervals.

Apple Trees with Straight Down Rootstocks (*J. B.*). — It is difficult to deal with trees that have the stems deeply buried and the roots practically beyond the reach of control. We have not carried out the system you propose on fruit trees, not having the misfortune to come across any in such case as you describe; but we have had young forest trees similar to deal with, and found ringing the stem about 6 inches below the then surface answer perfectly, the descending current causing a callus to form from the upper edge of the bark, and roots to be emitted plentifully. Thus in the course of two or three years the sickly trees recovered, and had abundance of roots near the surface. We should not hesitate to act in a similar manner with your trees. We should not make the ring more than 6 inches from the surface, and not more than three parts round the stem in the first instance; but the other part you may notch—straight cut on the upper side, and sloping one upwards to it, so as to arrest the downward current to a great extent without actually preventing the ascent of the sap by ringing all round at once. If the ringing were carried out now in a careful manner it is likely that you would not only secure a callus and some new roots by autumn, but also so arrest the sap in its downward course as to concentrate the assimilated matter on the buds, and induce the formation of blossoming ones. Thus you may be able to secure some fruit next year, at least the chances lie in that direction, nothing bringing overluxuriant trees into a state of fertility sooner than the concentration of the juices on the buds, as is the case in ringing judiciously performed.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*D. W.*).—The correct name of the Orchid you send is Lælia lobata. (*O. P. S.*).—1, Polystichum aculeatum; 2, Microlepia hirta cristata; 3, Nephrodium setigerum. (*C. F. A.*).—Euphorbia Lathyrus, the Caper Spurge. (*A. A. B.*).—1, Limnanthes Douglasi; 2, Lychnis coronaria; 3, Linaria reticulata var.; 4, Œnothera Lamarckiana; 5, Lychnis chalcedonica.

THE DIFFICULTIES OF DAIRY FARMING.

The British dairy farmer is constantly being taunted with the fact that he is allowing foreign countries to drive him out of the market by supplying a better article at a lower price. That the B.D F. is in fault it would be foolish to deny, but the question is then raised as to whether he is so much to blame as his manifold advisers think. Any of us who know the British farmer in his home see plainly enough that he is a man of great suspicion, and rather obstinate. Taken as a body, there is no spirit of co-operation existing. He looks askance at his neighbour, doubts his ways and methods, and above all, he sincerely hates any scheme which would allow of outsiders getting any data to go upon as to his financial standing—indeed, in many cases he would rather come to grief, relying on his own resources, than by the help of co-operation stem the flowing tide.

Farmers are too self-contained; their habits, manner of life, and old customs stick to them so tenaciously that it will take more than a generation to broaden their views and enlarge their sympathies. A great deal of this spirit has arisen from diversity of holdings, landlords' restrictions, and the severe competition in better days for every bit of land worth having, and the plethora of farm pupils (save the mark), who, incapable of taking up any other decent business, have been pitchforked into farming, with little or no knowledge and a fair amount of capital, which they soon dissipate.

In the dairy trade the milk-selling branch would be much benefited by co-operation. Large customers can dictate to the railway companies with more chance of attention than single individuals. Putting aside the question of adulteration as beneath our notice, it is a known fact that milk supplied by two or three farms is not of uniform character. In the first place, the feeding

properties of one farm may be vastly superior; secondly, one man may be a better judge of milking stock; in a third the milk itself, though possibly poorer in quality, may be better prepared for market. Now, till the quality is uniform there could be no possibility of agreement in any way.

Just the same with the butter. Made in small quantities it is sure to be very different in quality and texture, and in exceptional seasons of drought, such as 1893-95, the supply is most irregular. As long as trade is good there is a great demand for milk in the large towns—in fact, the great proportion of our cows are supplying the milk trade alone, and we must import butter and cheese. Then comes a time of trade depression, milk is thrown on the farmer's hands, and must, being a most perishable article, be turned at once into marketable goods.

If this surplus of milk could be manufactured at a creamery into a uniform article it would be good and easily saleable, though possibly inferior to what is made in first-class dairies that have all the modern appliances. The cost of a creamery is large, and it could not be maintained on a small scale at all, and unless the farmers can be satisfied with the price allowed for the milk the thing would be a failnre.

Now, the much-vaunted Danish factories allow 3½d. per gallon, with skim milk returned, the average price of butter being 8$\frac{4}{9}$d. per lb. Now, this would not satisfy the Englishman, for at the Sudbury creamery the prices have been 6$\frac{1}{40}$d. per gallon, and this has not proved remunerative to the producer. It is not that he grasps at an enormous profit; he only asks for just a living margin, and this he does not get. Taking an average cow, which will supply 500 gallons per annnm, at 3½d. per gallon, or 5d. per day, how can that cow be fed and tended for that amount? We cannot do it in England.

Our Swedish Minister, Hon. Hugh Gough, mentions a dairy in Sweden where twenty-five farmers work 2807 acres of land. They produce 182,819 gallons of milk per annum, or 64 gallons to the acre; this at 4d. per gallon would realise £1 1s. 4d. per acre, and out of this comes rent, taxes, working expenses, and farmer's profit!

How is it done? We cannot do it here. We are indebted to an excellent article of Lord Vernon's in "Nineteenth Century" of February for these facts and figures, and we will quote him further, *re* Derbyshire. He speaks of sixty-two farms in that county with a total acreage of 4561 acres, 3988 of which are grass, the remaining 573 acres arable. This farm or farms carry 1020 cows, which supplied 545,120 gallons of milk per annum. This is equal to 121 gallons per acre, or double the quantity on the same area in Sweden.

Now, then, as to expenses. Imperial and local taxation rates, 2s. in £; land tax, 1s. per acre; income tax, 6d.; and tithe charge of 3s 6d. per acre would amount to £1716. We find no mention of taxation in Denmark or Sweden, but we may fairly conclude these charges will hardly equal ours, with our costly machinery of county and district supervision.

Then comes the labour bill. In our dairy districts the wage is about 15s. per week with house and garden, 18s. without; and each man can do ten cows, so the labour bill for 1020 cows would be something like £91—16s. per week, or £4732 per annum. Now in Denmark men from fifteen to thirty years of age are content with £10 to £14 per annum, with board and lodging; older married men earn from 10d. to 2s. per day according to time of year, with food found. Therefore the wages would average 10s. 6d. per week, or the sum total of £2782 per annum, as against the English £4732.

As regards their living it is comfortable according to Continental ideas. Are those ideas English? We fancy not. The English farmer's average price for milk does not exceed 6d. per gallon; the consumer pays at least one and half times as much. If the producer and consumer could be brought into nearer touch the consumer would get his milk cheaper, and probably would take more of it. If railways could see their way to lessening the carriage of feeding stuffs more cows could be kept, more hands employed, and more land cultivated.

Where the holdings are small factories for butter and cheese would be very desirable. The raw material (milk) would be made up to the best advantage with the best possible "plant," and under the best possible supervision. Everything would be scrupulously clean, and every new invention (labour saving) would be taken up and adapted at once. The farmer would then be free to give his time fully to the best management of his stock, would sell his milk direct to the factory, have no bad debts, and uniformity in price all the year round.

Where the majority of holdings are large, as is the case generally in England, there has not been much inducement to provide factories, each farmer preferring to do all his own work, and with his greater capital he has been able to do it fairly well.

WORK ON THE HOME FARM.

Turnip drilling is nearly complete. Mangolds and early Turnips are growing fast, and require constant attention with both hand and horse hoe. We have nearly finished cleaning the Potatoes, and are now sowing the top-dressing and earthing up immediately. We are using 3 cwt. of superphosphate, and 2 cwt. of sulphate of ammonia, sown by hand separately.

Wheats are growing very well, they have had just the rain they want, and this heat is exactly the thing to suit them now; the ear is just leaving the blade, and promises to be strong. Everything points to a good Wheat crop where the plant is good, unfortunately a good plant is the exception rather than the rule.

Hay, or rather Clover, making is now becoming general, many pieces being cut and the subdued rattle of the mower being often heard. The Jubilee perhaps spurred farmers on to get their Clover before the 22nd. We fear that crops cut now must be light, the recent rains having not had time to effect much improvement in weight. How little we hear of ensilage nowadays, a dry summer suitable for hay-making appears to have driven it out of mind as well as out of sight.

Roots being all sown, and hay carting the only serious horse labour between now and harvest, we can give our horses, or at least a portion of them, a six-weeks run and rest. As grass is beneficial to the system of any animal, so also to a horse is great benefit to be derived from it, particularly if a good rest from both hard corn and hard work can be allowed. There is not only the saving of the corn to be considered, but an abstinence from corn, always more or less heating, is most beneficial in cooling the system.

It is a good plan to turn carthorses right away on as low lying cool a pasture as is available, and let them stay there until they are required for the leading of the corn.

REMARKS.

13th.—A perfect summer day.
14th.—Overcast early; frequent sun, tempered by cloud and breeze, after 9 A.M.
15th.—Fine and pleasant, but frequently cloudy.
16th.—High wind all day; showers at times till 11 A.M., bright sunshine after.
17th.—Generally sunny, with fresh breeze, but cloudy intervals; overcast night, with slight showers.
18th.—Steady rain from 1.30 to 5 A.M.; generally overcast and windy, with short, sharp showers.
19th.—Generally overcast, but occasional sun; rain at 8.30 P.M. to midnight.
Much cooler at the end of the week than at the beginning, so that on the whole it was one of average temperature.
20th.—Generally overcast, with some sun at times.
21st.—Alternate cloud and sunshine, hot at times.
22nd.—Overcast till 11 A.M., generally sunny after; solar halo at 5 P.M.
23rd.—Hot and fine, but rather hazy and close in morning.
24th.—Cloudy and close early; slight shower of large drops at 9.30 A.M., and brighter after; sudden squall at 2.6 P.M., and thunderstorm from 3 to 6.16 P.M.
25th.—Overcast throughout; drizzle in evening.
26th.—Drizzle early, and overcast till 11 A.M.; generally sunny from noon.
A fine warm week, with about the average rainfall.—G. J. SYMONS.

Journal of Horticulture.
THURSDAY, JULY 8, 1897.

HONOURS IN HORTICULTURE.

AS was intimated some time ago, the Council of the Royal Horticultural Society decided, in commemoration of the sixty years of her Most Gracious Majesty's reign, to strike a new medal, to be called "The Victoria Medal of Honour in Horticulture," to be awarded solely *honoris causâ* in the domain of horticulture. It appears the Council decided to award not more than sixty of these medals during the present year, a further award only to be made on the death of one of the existing holders, in order that the number of living Victoria medallists may never at any time exceed sixty, who must be subjects of her Majesty at home or in the colonies. The essential condition is undoubtedly a just one—namely, that the recipients must be actual subjects of the Queen, and the limitation to sixty is equally appropriate as corresponding with the number of years of the great reign hereby commemorated.

The *Journal of Horticulture* gave to the project a frank welcome at the outset. The event, which horticulturists so strongly desired to celebrate, was felt to be so unique that a flower show alone, however great, with medals to exhibitors, would not, even if practicable, adequately meet the occasion, and do sufficient honour to an event the like of which has never before occurred, and in all probability will not occur again in a thousand years.

Exhibitors of garden produce have done splendid work, and well deserve the honours they have won; and they are not deprived of the opportunity of winning more by this memorable departure of the Royal Horticultural Society—on the contrary, special opportunities are provided for them at the forthcoming Royal commemorative show at Shrewsbury.

It has also to be noted that though the Council of the Royal Horticultural Society has taken a broad statesmanlike view of the subject which had to be considered, and gone beyond the domain of exhibitors, these as a body have in no sense been excluded. This is apparent, for it can be seen at a glance that a full proportion of the first "Victoria medallists" have been, and some still are, prominent exhibitors, and have won high honours in the competitive arena.

Than the most intelligent and most successful exhibitors at shows, there are no persons more

cognisant of the fact that, outside the question of showing, there are men who have in various ways and over long years of endeavour done something worthy of recognition in placing the great art of horticulture on the firm basis on which it stands to-day.

Its present status could not have been attained in the absence of generous patronage, scientific research, the devotion of explorers, the skill of hybridisers, the enterprise of zealous men, quiet experimental work in the garden and the laboratory, and midnight labour at the desk. One section alone, and any section, could have done comparatively little in bringing gardening into its present condition. It is by the combination of effort on the part of many men in diverse ways that Britain stands at the head of all the world in horticulture. Yet the fact is indisputable that those men who have striven to share, each in his own sphere, in advancing the cause of gardening, have had no incentives to urge them on beyond the calls of duty, and until now no special public recognition of their services from high official source. The Royal Horticultural Society has found a way to bestow a token of honour in commemoration of the greatest historic event of the century, and has honoured itself in doing so.

That the honours have fallen where everyone would desire is a question that need not be discussed. It must suffice to say that there is not wanting evidence that extraordinary pains have been taken to ascertain the views of a large number of horticulturists on the question of allocation. If we mistake not, the decisions are based on a plebiscite—a vote of the House of Commons, so to say, collated by the House of Lords—the Council of the R.H.S. If we were inclined to criticise the final decision, we should begin by saying that the Council has not been over-generous to its own members. True, there are some three or four of the body who are honoured, but the majority, certainly, if not every one of them, must, we should think, have been voted as recipients of the medal if they had no seat at the board.

The list of the first sixty gentlemen on whom the distinction has been conferred we publish in alphabetical order precisely as received. It will be perceived that the list is widely representative, as composed of patrons and workers, botanists and other scientists, authors, orchidists, raisers of new plants, rosarians and other florists, fruitists, an eminent landscape gardener, nurserymen, seed merchants, a great Covent Garden Market salesman, market growers, and not least in numbers practical gardeners.

ORIGINAL VICTORIA MEDALLISTS.

Burbidge, F. W.
Bunyard, G.
Barron, A. F.
Baker, J. G., Kew
Balfour, Professor, Edinboro'

Veitch, H. J.
Wilks, Rev. W.
Wolley-Dod, Rev. C.
Wright, J., *Journal of Horticulture*
Wythes, G., Syon
Wilson, G. F.
Ward, Professor Marshall

That the honour will be appreciated by every one of the recipients there can be no doubt, and not the less so since the medal has been struck with her Majesty's express sanction and approval, and being "solely *honoris causâ*" will, of course, not be used by the recipients for any trade advertisements or such like purposes; but each recipient is authorised to put V.M.H. (Victoria Medal of Honour) after his name, as indicative of the highest distinction that can be conferred in the horticultural world.

HARDY FLOWER NOTES.

As we enter the garden we are welcomed with the song of the flowers, as their perfume has so well been termed. It comes to us sweet as the carolling of that lark which, afar off, sings in the heavens its morning song. Each movement of the air brings with it fresh fragrance exhaled from the flowers. It comes from the Pinks now so sweet with their perfume and so delightful in their beauty. It comes from the Rose, though a little later the queen of flowers will yield us more of her delicious odours. It comes from the Honeysuckle—the emblem of faithfulness—which hangs over the wall and clambers up the Hawthorn tree. This song of the flowers—a wordless, inaudible melody—touches us with its sweetness, and endears to us the flowers which give it birth. That Rose, that Pink, that Honeysuckle, have within their petals the quality which is to the flower what talent is to the manly and the beautiful, an added virtue, the crown of all. Of the Rose others can better tell; others can better reveal its loveliness, its graces, its fragrance.

The Pink has fewer worshippers, and these, like the writer, are more eclectic in their tastes, owning allegiance to no particular flower, but seeking to draw pleasure from many, yet its fragrant and beautiful flowers have made it a favourite in long past years. It is one of Jove's flowers—a Dianthus—and though eclipsed by the sister flower—the Carnation—should never be absent from the garden's bounds. With me, on account of old associations, the old white garden Pink will ever be a sacred flower, but the newer varieties are none the less admired. The large old plant of Mrs. Sinkins, which for several years has grown bigger and bigger in one of my borders, is larger than ever this year, and has more flowers than ever before. Many a sacrifice has it to offer to the Lares and Penates in the shape of cut blooms. Some day it will die of old age, but we hope that day may be far distant, and that younger plants may then be able to supply enough of the odorous flowers. Some of the new Pinks raised by Mr. Ladhams and others are of the highest merit in the garden.

Following use and wont it will not do, however, to write at large of the Pink, and one may aptly speak of one of the genus to which it belongs. This is Dianthus superbus, the Fringed Pink, which, by reason of its generally short-lived nature, is not so often seen in gardens as it ought to be. This is not because of its delicacy or inability to stand cold, but probably because of its less truly perennial habit. It is said to be a perennial in light, dry soils, but experience in my garden and elsewhere does not bear this out. Last year I saw it in Ireland planted in a small bog in a rock garden, where it would not be crowded with other plants, and where its seed would fall and be likely to germinate readily.

It had been planted there by an experienced cultivator of such plants, and one is quite prepared to find such a method of cultivating this pretty Pink prove successful. It does not appear to be very widely known among growers of hardy flowers, so that this note may do some service in bringing to their notice a flower of distinct appearance. The blooms begin to appear about midsummer. They may be called rose-coloured, and have the petals cut up by deep divisions, which go deeper than the centre of the petal. The flowers are feathery, and are produced on many-flowered stems 10 to 18 inches high. The leaves are narrow and bright green. The Fringed Pink is easily raised from seed, which may be sown in spring in pots or pans, or in the open ground.

Not many of the Irises have fragrant flowers, but their beauty of form and bright colouring make them ever attractive. This is emphatically the month of Irises, when the different Flag, or German, English, and Spanish varieties give the garden much of its summer glory. But even these, numerous as are their varieties, form only a portion of the richness of the material for gardening offered by the Irises. There are many very beautiful species which are at once easy to cultivate in the garden, and full of elegance and grace in habit and colour. Among these is Iris Douglasiana, a Californian species, not much known, and not so easily procured as some.

I was reminded that I had never mentioned it in the Journal by the arrival of a cut bloom from a plant received under this name by a good friend of mine, who has a large collection of hardy flowers. It proved to be the form of I. Douglasiana known as the "Santa Cruz variety," which has whitish falls, a yellow keel, and claret purple veins.

I have had for some time in my garden a plant as Iris Douglasiana, without having much opportunity of verifying the name from living specimens, but it seems correctly named, and is, as I write, in full bloom. Mr. J. G. Baker gives the type as having the falls "pale lilac, with darker lilac veins." This is exactly the colour of my specimen, but I learn from another source that in California the species varies in colouring, and that purple, lilac, pink, rose, and yellow forms are to be found. It belongs to the Apogon or beardless section, and has linear leaves from 1 to 2 feet long, with the flowers produced on stems from 6 to 12 inches long. It grows here in a dryish border of sandy soil, and has been quite hardy for several years.

Lest it should be forgotten later in the season one would like to say something about a dwarf-habited Poppy which, through the kindness of one of our most learned growers of hardy flowers, was sent me last year. This is "Mr. J. Carrington Ley's Hybrid Poppy." It is an acquisition, but I have puzzled myself over its parentage. It is like a dwarf small-flowered Papaver bracteatum, perhaps the richest coloured of the great perennial Poppies, but is without the leafy bract at the base of that variety of P. orientale. It may be a cross between P. bracteatum and the ordinary P. orientale. I observe in the Kew "Hand List of Herbaceous Plants" that there is grown there a hybrid of P. rupifragum and P. orientale, but there is nothing to indicate its appearance. From Rev. C. Wolley Dod I have hybrids of P. rupifragum closely resembling that species.

It may arise from my own slowness of observation, but it seems to me that neither of these "hybrid" Poppies presents conclusive evidence of hybrid origin, further than that Mr. Carrington Ley's one may have come from P. orientale and P. o. bracteatum, which is only considered at Kew a variety of the former. However this may be, Mr. Carrington Ley's Poppy is a valuable little plant. It is of dwarf habit and neat in its way, growing only about a foot and a half high in the light soil of this garden. But I have said enough on such a question, and let me close with a look at the flowers in bloom as I write.

There are, besides those spoken of, Mulleins, Potentillas, Geums, Pyrethrums, majestic Delphiniums, tall and dwarf Campanulas, Lupines, Sea Hollies with spiny flowers; Foxgloves, into which the humble bee loves to enter; Snapdragons, Irises in many kinds and colours, Rock and Sun Roses, annual and perennial Poppies in great profusion, and a host of others. Untold wealth of beauty indeed, tempting us to sit in the Rose-covered summer house and dream the day away, sallying forth now and then to wander among the flowers. Unprofitable in some ways it might be, but in others not in vain.—S. Arnott.

LIGHT AND ITS INFLUENCES.

We are mostly aware how indispensable are air, heat, and moisture to the development of plant life, but how intimately the agency of light is connected with that operation is not matter of such common knowledge.

By light we mean the diffusion of solar rays, which are always in a greater or lesser degree illumining the earth. This emanation by means of rays is attended by two results—viz., heat and light, which further effect a great chemical change. Whether these three be different manifestations of one grand principle or three distinct ones, science has hardly yet satisfactorily determined. Thus it is possible, for instance, to receive heat and throw back light, or admit the light and obstruct the heat, and it is also possible to produce chemical effects which neither heat nor light combined or singly can produce. The chemical influence of sunbeams, which we call actinism, may act on substances unaffected by heat or light. Assuming, then, that solar radiation comprises three different sets of rays, let us point out some of the most obvious effects of light and actinism on plant life.

The germination of seed is the change of the inert embryo into a living plant, effected jointly by heat, light, and moisture. Light is destructive to this process, for it is only in darkness that vigorous germination is induced. But while the sun's rays retard the vivification of the embryo, the actinic rays forward it. Southern aspects are always clothed with more elaborate and developed plants than northern sites, and this results from the greater light the former enjoy. The north may be as verdant, but it will never be so flowery as the south exposure.

It would appear, therefore, that actinism is a more subtle force than air, heat, light, or electricity in the development of vital energy. When a sunbeam falls on a leaf it induces a change of colour. The green hue so prevalent in healthy vegetation depends entirely upon light. Grow a Potato in a dark cellar, and observe how any feeble ray of light which enters attracts it. It may have grown for months to the extent of some feet, and yet no trace of green is visible until it has come within the influence of solar light, which in even a few hours will give it its natural hue.

In America the operation of light in colouring leaves is seen in a grand and striking manner. Over the vast forests clouds often spread for days, interrupting the rays of the sun. It was noted on one occasion when the sun had not shone for three weeks, the leaves of trees had reached their full size, but were pale. One morning the sun broke through the clouds, and as a result in the afternoon of the same day the whole forest exhibited its natural summer dress. It is not to be inferred, however, that continual solar light is a normal condition. On the contrary, plants require a period of repose from that activity which actinism ever excites.

Our home vegetation springs, grows, and ripens slowly under alternate conditions, requiring several months for its proper development; but in Arctic regions, under continual light, plants start suddenly into existence, and go through their life in a few weeks. Dr. Lindley truly says that diurnal changes of light and darkness are necessary for the well-being of plants, for if they were always kept in light they would be ever decomposing a great constituent—carbonic acid—and would consequently become stunted, and there would be no trees, as is actually the case in the Polar regions.

Grown in darkness their tissues become lengthy and weak; no carbonic acid decomposes, no parts acquire solidarity and vigour, and they soon die. But under natural circumstances plants which in the day become exhausted by the decomposition of their carbonic gas repair their strength at night by inhaling oxygen copiously, so forming a new supply, and absorb moisture from earth and air without losing any portion of it. It will be seen, therefore, how important is actinic light by its effects on inanimate objects as well as animate ones. Organic life is thrown into motion by its influence, vitality is revivified in seeds, and even inert matter changes its colours and properties.—Wm. Norman Brown.

HORTICULTURAL HISTORY NOTES.

The Apothecaries' Garden, Chelsea.

Those speculators who are constantly on the look-out for eligible building sites about the London suburbs, have often cast longing eyes on the old "Physic Garden" at Chelsea, and have, indeed, made various efforts to get this ground converted to other uses, which would involve the destruction or removal of most of the plants now growing there. It seems a pity that this small space cannot be kept intact and maintained as long as possible in its present condition. I would hardly advocate its being thrown open to everybody, which might not be advisable. A small charge could be made to visitors. Really there are strong reasons for its preservation; this garden should be of great interest to members of the medical profession, to botanists, and all lovers of those fragments of a bygone London which yet remain. We may say, besides, that the place may be considered to have for several reasons special associations with our Royal Family. Certainly it has been an important means of advancing British horticulture during the Georgian era, if not since. Therefore the Diamond Jubilee of Queen Victoria suggests itself as a very suitable time to secure this historic space against future attacks. About 1875 the now defunct Metropolitan Board of Works endeavoured to acquire the garden, intending to dedicate it to the people of London, but the scheme failed. It may be possible for the London County Council, aided by some of the wealthy residents in Chelsea and neighbourhood, to accomplish what was then left undone before it is too late.

The early experiments of the Apothecaries' Company in the direction of horticulture seem to have been made somewhere about Westminster, but the exact locality of their first garden is unknown; probably it was somewhere near Millbank, for in the Stuart days there were many gardens along the Thames between Westminster and Chelsea. Part, indeed, of the old "Pest House" fields, now absorbed into South Belgravia, was open ground till after her Majesty's accession, supplying vegetables and fruit to the adjacent suburbs. Mention is made by Evelyn of a medical garden existing here during the Protectorate; this may have been the same plot which the Society of Apothecaries, in 1676, were holding of a

Mrs. Gape, expecting shortly to remove their plants to Chelsea. Several things might have induced them to select this locality for their garden, one near the Old Swan Tavern, a house well known in the seventeenth century, and very conveniently situate on the river's bank. Chelsea, too, then a "village of palaces," had already a repute of being a favourable spot for plant growing, for several of its mansions had extensive gardens in which foreign species had been introduced. To the east of the Apothecaries' garden, at no great distance, were the grounds of the Earl of Ranelagh, a nobleman who was reputed to have done much for the advancement of horticulture in the reign of the third William. Bowack says that "the plots, borders, and walks were curiously kept and elegantly designed;" the greenhouses also had few rivals at that time. Swift, however, with his wonted bitterness, calls Ranelagh "the vainest old fool he ever saw," perhaps rightly.

We can trace the history of this three acres of land, or about that, to the reign of Charles I., when they were conveyed to Edward Cheyne by Sir A. Gorges, being then an open field. In 1673 Charles Cheyne let the ground on lease to the Society of Apothecaries for £5 yearly; the next year it was walled round and partly planted with herbs. It was not the oldest botanic garden in England, as some have stated; several preceded it, such as Gerard's and Tradescant's, also near the metropolis. John Watts, a botanist, who had helped on the enterprise from the first, became curator and manager in 1680. Only five years after Evelyn records a visit he paid the garden, when he saw hosts of novelties, especially many rare annuals. By this curator one of the earliest stoves was constructed, heated by pipes—for the first greenhouses had open fireplaces. Petiver was chosen in 1709 as demonstrator of plants, his extensive collection of natural history objects afterwards passing to Sir Hans Sloane by purchase, and now forming part of the British Museum.

But the grand turning point in the history of these gardens was the generous action of the above baronet, who had acquired Chelsea Manor from the Cheyne family. Had it not been for this they would not probably have had their long-continued existence and usefulness. For the merely nominal rent of £5 he gave the Company right to hold the ground in perpetuity as a medical or botanic garden. There was one important condition—that the Company should transmit yearly to the Royal Society fifty specimens of new plants grown by them until the number of 2000 had been reached. This delivery commenced in August, 1722, and ended in July, 1774, the total of 2250 being made. It was all the more noble of Sir Hans to do this because he had been at issue with the apothecaries, who had angrily opposed an excellent scheme of his for the formation of free dispensaries to benefit the poor. Could they do otherwise than raise a statue to their honoured friend, which Rysbrach completed in 1737, and which yet stands, much dilapidated by the wear of many summers and winters? Doubtless the baronet was, through his numerous correspondents, often the means of bringing scarce or exotic species to the gardens.

The illustrious Linnæus visited the Chelsea Garden in 1736, and he notes that he was permitted to take away numerous specimens; afterwards he wrote high praise of Miller, and others engaged there, with whom he corresponded. Apparently the grounds were a frequent resort of visitors from all parts of England, and from abroad; seeds or plants were also obtainable sometimes by outsiders. Charles Hatton, in a letter, mentions that he brought away two pots of Passion Flower, and Horace Walpole went there to get seed of the Tea Plant. But the Society never made any large profit from the gardens, and, indeed, has spent a good deal year by year upon them to the advancement of botany and horticulture. Ever since 1837, when Dr. Lindley first called attention to the fact, the increase of houses and factories has been unfavourable to the plants generally, the air being thereby somewhat polluted. The embanking of that part of the river added a little land to the Physic Garden, but it caused the death of an unusually fine specimen of the Oriental Plane.

Amongst those who have had the Chelsea Garden in charge probably Miller is entitled to the place of pre-eminence. Some foreigners, we are told, called him the "Prince of English Gardeners." He rose through his own diligence and skill, making his start under his father in a small market garden at Deptford. During a period of almost half a century, starting from 1722, he worked assiduously at Chelsea, introducing many new species and varieties, also preserving forms which would otherwise have been lost. No doubt, towards the end of his connection with the Apothecaries, he assumed too much power, which led to his retirement. Miller acted as adviser to a large number of noblemen and gentlemen when they were planning or laying out gardens. His "Gardeners' and Florists' Dictionary" went through many editions; it was the result of twenty years' study, and prepared the way for more comprehensive modern works. It was in Miller's time that Elizabeth Blackwell frequently visited the Chelsea Garden while engaged upon her Herbal. William Aiton, who afterwards played a very important part in the history of Kew, was instructed by Miller, one of whose sons subsequently took the post of first curator at the Cambridge Botanical Gardens. Dying in 1771, Miller left a record which led, after some delay, to the erection of a memorial obelisk at Chelsea by the Linnæan and Horticultural Societies.

To those who passed the Apothecaries' Garden in the early decades of Queen Victoria its pair of Cedars were familiar landmarks, survivors of four planted in the reign of James II. Of these two died between 1760 and 1770; the two left attained their full size about 1830. One of these had to be removed in 1878; the other is also dead now, I believe. Of the trees which date from the reign of George III. or earlier few remain. Amongst those presumably introduced by Miller and extant till recently, I may mention specimens of Quercus Suber, an aged Pomegranate, a fine Pistacia terebinthus, a Paper Mulberry, a Maidenhair Tree, and a remarkable plant of Styrax officinale on the wall next Swan Walk. There was a Celtis australis, supposed to be about the age of that Evelyn saw just set at Lee Court in 1683, and a large Magnolia grandiflora, probably a descendant of the first British arrival, which was planted at Exeter, and furnished offshoots to many gardens. Here, also, were some Phillyreas, a shrub formerly much more popular about London suburbs than it is now.

The immediate successor to Miller was Forsyth, the man of the "tree plaister," for which he succeeded in extracting a handsome payment from the Government of his day, though the recipe has really no important value. It was to heal wounds, and also restore vigour to decayed trees, being composed of fresh cow manure, lime rubbish (preferably from ceilings), wood ashes, and a little sand. Any benefit arising appears to have been simply by its action in excluding moisture. After 1784 he entered upon the position of gardener at Kensington Palace, leaving Chelsea, and died in 1804. He had, no doubt, much knowledge of fruit and forest trees. A friend of his, Mr. Wedgwood, is said to have thrown out hints in 1801 which led to the formation of the Royal Horticultural Society.

Amongst many honoured names connected with the Chelsea garden are those of William Curtis, demonstrator for some years, and Dr. Lindley, who held the like position; Isaac Rand, W. Anderson, and others whose memory is yet green. A curious collection of seeds, containing thousands of species, was formed by Rand, but I expect this has perished. Mr. Thomas Moore, F.L.S., was the last curator. He died in 1886, his predecessor being Mr. Robert Fortune. Those who are interested in such structures may still find at Chelsea the relics of old style greenhouses, which remind us of the disadvantages a gardener of last century had to contend with.—J. R. S. C.

EXPERIMENTAL WORK IN HORTICULTURE.

(*Concluded from page* 520, *last vol.*)

A NOTED French scientist has said that "an experiment must have an object, and be based upon an hypothesis." As to the first part of the dictum there can be no question, for it cannot be too clearly understood and laid down what the object really is, for chance exploring is very unsatisfactory work; discoveries are occasionally made, but there is much wasted and misdirected labour. Whether it should be based upon an hypothesis is not so clear, though there is an element of truth in it, as few can adopt any particular treatment or any special substance without forming an idea regarding what the effect will be, even though the result may completely negative the assumption.

It appears to me, as doubtless it has to others engaged in experimental work, that it is important to keep the mind as clear as possible from preconceived ideas, lest one's judgment be influenced in any degree in observing the results. It is also necessary to simplify the object of research, and if there is a difficulty about separating complicated conditions it is best to have several experiments directed to dealing with the various points individually. The same object must also be kept constantly in view in dealing with the same plants, and however tempting it may appear at times to follow up some fresh idea, it is wiser to pass it by until opportunity occurs for prosecuting it on an independent basis. In determining the objects to be studied a thoroughly intimate knowledge of the subject in all its details is requisite. Considerable time may be devoted to investigating what is already well known, or to seeking what is of no practical value whatever. The best results can only be expected where there is

already knowledge and a corresponding desire for extending and strengthening it because its weak points are recognised.

The methods adopted will necessarily depend upon the subjects to be investigated, but there are some general preliminaries that should always be observed. The first is to subject as many individual plants as may be convenient to the same kind of treatment; this increases the value of an experiment greatly, in direct proportion indeed to the numbers of plants dealt with. If it be then possible to watch the growth and variation of the individuals forming the series over a lengthened period of time, still further valuable facts for checking observations and modifying conclusions will be obtained.

The second matter of urgent importance is insuring a uniformity of conditions, and in dealing with plants under glass this can be done to a large extent, for soil, heat, and moisture are under full control. With regard to plants or trees out of doors it is not so easy of accomplishment, as though it may be possible in a small way to have soil specially prepared for plants in the open, on a larger scale the only means is to have a series of careful soil analyses prepared, and then to keep an accurate record of all that is supplied subsequently. Even then, however, there are possibilities of differing conditions interfering materially with the results. Unquestionably the most satisfactory method is to prepare a soil of which the constituents have been determined, and the exact weight should be taken, whether the plants be in pots or beds.

If the plants are to be raised from seeds these should be weighed, and the number to any particular weight determined; while if rooted plants are to be used these should be both weighed and measured, so that as many details as possible may be at command. When water or manures are supplied the quantities must be exactly noted, and the times of application should also be the same for the whole of any experiment. It is obvious that these remarks apply chiefly to cultural experiments, as in cross-breeding there are many conditions that would require discussing at greater length than the limit of this letter will permit, though it may be returned to on another occasion.

A word or two must be given to the noting of results, for this may affect the whole work of the observer. Frequent observations should be taken at regular intervals of the condition of the plants, growth, foliage, and flowers all furnishing characters for record, together with fruit or seeds in the case of some trees and vegetables. No point of difference should be considered too small for notice, and nothing must be overlooked; in fact, the subjects must be studied with eager and intelligent interest.

When the condensing and analysing stage is reached still further care is needed, for in dealing with any form of life it is so easy to found a wrong conclusion on limited evidence, that it is wise to withhold any definite judgment until one series of observations has been confirmed or modified by subsequent experience. To those who have devoted many years to such work it is astonishing, and sometimes confounding, to find the opinions which had been apparently founded upon such sure grounds completely upset by later knowledge.—OBSERVER.

CAMBRIDGE LODGE.

THE collection of Orchids at Cambridge Lodge is so good that one may pay a visit at any time and be sure of finding a number of flowers open to interest them. Then there are the thousands of plants of all kinds that even if they are not in flower must have attention on account of the excellent condition in which they are always to be found. Several journeys have been made at various times, but never without some information having been gleaned, and something of more than average interest seen. There can be no doubt that Mr. H. J. Chapman, the grower, is easily a master of his craft, and that R. I. Measures, Esq., the owner, is an orchidist in the best sense of the word, and grows the plants either for the beauty of their flowers or by reason of the botanical interest attaching to them.

If we accord the premier position to plants that were in flower we must put the Miltonia vexillaria first, for they were, and probably still are, making a really superb display. The forms and colours vary very considerably, and while some are deep in hue and large in size, others are softer and smaller, all being good. The plants as a rule are not very large—such not being desired—but the excellent health they were in, and the splendid spikes of flowers which they produce, prove the correctness of the system of culture adopted. Very conspicuous was a variety with white flowers, the lip of which was of enormous breadth and fine substance. Flaked forms were also to be seen here and there, while others of a rich rose hue were abundant. The plants are

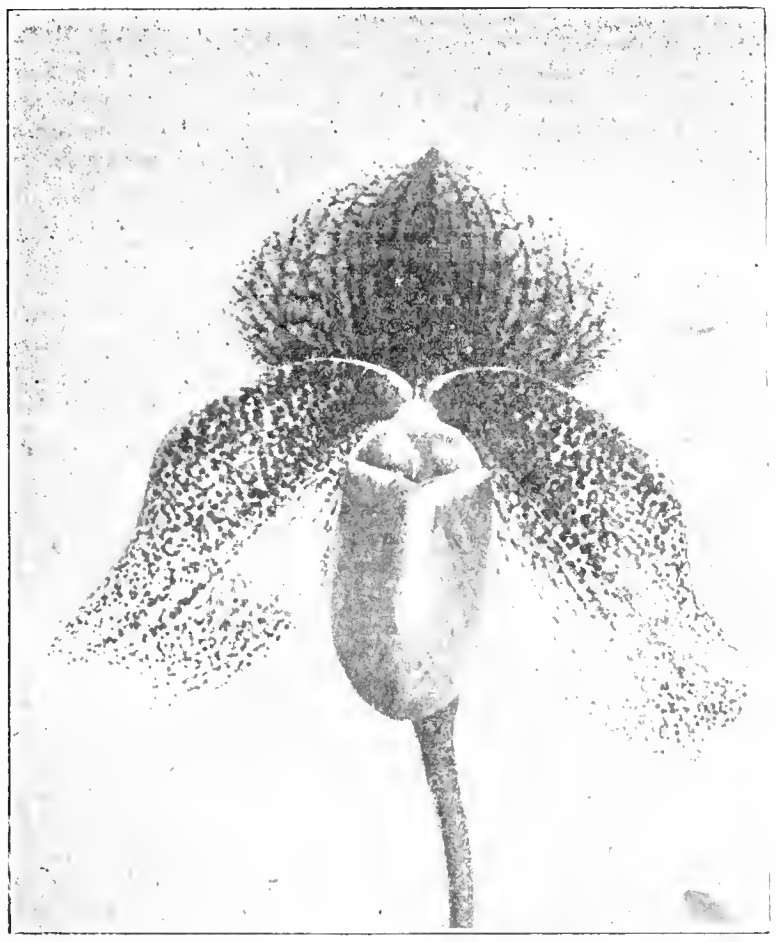

FIG. 4.—CYPRIPEDIUM CHAPMANI MAGNIFICUM.

arranged on the side stages of a square-built structure, and produce a charming sight with their flowers of diverse shades, greyish green leafage, and clean healthy growth.

If the Cattleyas were not making such a brilliant display from a floricultural point of view, they were no iota less interesting. The hundreds of labiatas, amongst which are many varieties of the very best quality, were looking remarkably well, and will probably render as good an account of themselves in the future as they have so often done in the past. Besides these there are hundreds of Mendelis, aureas, Mossiæs, and the several other types, whose chief characteristics were excellence of health. We have a recollection of seeing them in flower at different times, and can speak emphatically regarding the excellence of the stock in this respect. Not a poor weakly specimen was to be seen, while insect pests were equally conspicuous by their absence; all were clean and the foliage was wonderfully strong and fresh in appearance. This, indeed, is one of the most interesting sections of the whole collection.

Cypripediums are one of the specialties of Cambridge Lodge, and the collection is nothing less than a magnificent one. Almost every procurable species, hybrid, and variety is represented, while much of Mr. Chapman's time is spent in endeavouring to produce new ones by the aid of hybridisation. There are thousands of seedlings of various ages that have not yet flowered, and are not likely to do so for some years to come. These, it is anticipated, will give some splendid results. One of the most beautiful of this hybridist's results is the one represented by the illustration (fig. 4), which is named C. Chapmani magnificum. Our figure, while it represents the marking and the form of the flower, is not of life size—in fact, it is reduced considerably from nature. The variety received an award of merit at one of the Drill Hall meetings, and a first-class certificate at the Temple Show. The form was obtained from a cross between C. bellatulum and C. Curtisi. The round dorsal sepal is white, veined and spotted dull crimson, which is the colour of the petals. The pouch is of splendid shape and deep claret in colour. Many other Cypripediums could be named, but space now forbids it.

Exceptionally beautiful were the Lælias that were in bloom when this visit was paid, and the same may be said of the Dendrobiums, of both of which large numbers of plants are grown. Masdevallias make a glorious display as usual. Of these the stock is one of the finest in the country, comprising, as it does, the majority of the kinds and varieties in cultivation. Of the Aërides, the Vandas, the Cœlogynes, and others we cannot now say more than that they are in the most excellent condition—a characteristic of every Orchid on the place.—H. W.

Thunias.

These form a very useful class of Orchids, especially suited to amateurs, being interesting and of easy culture. The requisite heat being at command, a tyro in Orchid growing may take up their culture with every prospect of success, but without this they are better left alone. The warmest house, or what is usually termed the East Indian house, is most suitable, and the lightest and sunniest part of it should be chosen. They require even more sun than deciduous Dendrobiums—in fact, they will, for the greater part of the year, thrive well in an entirely unshaded position.

Imported plants come to hand in the shape of dry stems from a foot to over a yard in length, and these require very little to establish them if collected at the proper season, so as to arrive in a fairly plump condition. Stems that have been produced under cultivation may be potted singly as early in the new year as possible, first of all trimming off the greater part of the old roots, leaving only a few to steady the stems in position. Good spikes may be grown in 48-pots, and unless it is specially desired to have them massed one stem should be placed in each. If larger plants are wanted suitably sized pots may be used, and five or six placed in each, the only fault of this mode of culture being that they do not always flower simultaneously.

A good deal, of course, can be done by choosing stems of as nearly as possible the same size, and with the young shoots at the base in equally forward condition, but even so the result is not always satisfactory. Good drainage and clean dry pots are essential in either case, as the plants when growing freely take a lot of water. For compost take about equal parts of peat fibre, loam, and sphagnum moss, a little of the rougher portion of the latter being placed over the drainage. Mix plenty of finely broken crocks with the compost, but sand is not required. A little dried cow manure, or a sprinkling of an artificial manure of not too stimulating a character may also be added.

The surface of the compost for cultivated stems must not be raised above the level of the rim, but kept below as in ordinary potting. When newly imported a slight rise is advantageous, and in neither case must the base of the stems be deeply buried. Place a neat stake to each stem to prevent rocking about, tie firmly, and place at once in their growing quarters. The atmosphere must be kept very moist, and the young shoots will then lengthen rapidly. It will be noticed that when about 3 inches in length these commence to emit roots, and until this occurs no water should be placed on the compost, though light dewings over the old stems may be allowed. But the roots advance rapidly in ratio with the growth, and soon a full supply will be needed.

When they are well rooted and taking water freely, allow them free exposure to the sun, and as much air as may be without lowering the temperature. By the beginning of June the white-looking spikes should be showing at the apex of the stems, and they rapidly come to maturity. The blossoms being past, the plants may be removed to a light, airy, and warm house to ripen their foliage, the supply of water to the roots being lessened as this falls. During warm weather they may be placed outside with advantage, but an eye must be kept on the weather in August, and if likely to be cold the plants must again be taken inside. Any plants that are not showing spikes by the end of July must be gradually ripened off as recommended for plants that have bloomed.

It is important that the Thunia stems are not kept too cool during the winter, for like deciduous Calanthes they are easily injured in this way. If room is scarce they may be turned out of their pots and hung up in bundles from the roof, but warm and dry they must be. The present month (June) is their flowering season, and it is important that while they are in bloom no water is allowed to touch the flowers. Calanthes even are not more easily damaged in this way, so if left to bloom in their growing quarters great care is needful with the syringe. The best plan is to take them out while in bloom, and arrange them in a drier house. Thunias are readily propagated by division, one stem often breaking into two at the base in spring, and if a more rapid mode is desired the stems that have bloomed may be cut up into lengths of 4 inches or so, and rooted in pots of sphagnum moss.

T. alba is the oldest member of the genus, having been discovered by Dr. Wallich in the Himalayas; it was introduced to cultivation a few years after by Messrs. Loddiges of Hackney. It has pure white blossoms, marked on the lips with purple streaks. T. Bensoniæ is a native of Rangoon, and first flowered in this country in 1867 at Kew. The variety Winniana is more highly coloured than the type, having bright rosy purple blossoms. T. Marshalliana is perhaps the best known of all, and bears pretty white flowers much fringed on the lips with golden yellow hairs, while the hybrid T. Veitchiana was raised by Messrs. Veitch from T. Marshalliana and T. Bensoniæ. It is synonymous with T. Wrigleyana and first flowered in 1885.—H. R. R.

Diamond Jubilee Orchid Trophy.

On Monday, 21st ult., at Messrs. Wills & Segar, South Kensington, was exhibited a magnificent Orchid trophy, arranged by them for Messrs. F. Sander & Co., which consisted of a basket made of wickerwork, standing on a polished mahogany base; in shape trifoliate, beautifully fluted and plaited. From the three corners arose the handle, its three branches forming a dome, surmounting the top of which is a Royal crown, the letters "V. R. I.," 12 inches in length, being arranged beneath the crown, which consists of several hundreds of flowers of Odontoglossum citrosmum, the letters being composed of Epidendrum vitellinum. Spikes of many of all the best and rarest Orchids were used, among them being Cattleya Empress of India, Cattleya Our Queen, and Cattleya Victoria Regina. Odontoglossum Alexandræ were prominent in magnificent pure white spikes, as also were Dendrobium Dalhouseanum. The sprays of the Disa, Stenoglottis, Burmese Vandas, Cattleyas, Oncidiums, Epidendrum, and Lælia served to illustrate the vast floral wealth in Orchids indigenous to many lands over which our Queen reigns. The handles were fitted with flutes or sockets, in which the flowers were placed with the spikes entire. The interior of the basket, which had to be specially constructed, was one central dome, forming a solid foundation, supporting the mass of blossoms, which, perfectly finished and arranged, had a maximum height of 8 feet, with a diameter of 6 feet. By command of her Majesty the trophy was delivered at Buckingham Palace on Monday afternoon.

SWEET PEAS.

There were several large collections of these charming flowers shown the other day at the Drill Hall, and selections from them seemed to be exceedingly difficult. I could not but feel that had one-half of the so-called varieties never been put into commerce our Sweet Peas would have been much the better, and gardening none the poorer. Far too many of these Peas are put into commerce simply to sell, but to assume that they merit names or awards is ridiculous. There lies before me a list of ninety-five so-called varieties. Talk about things undreamt of, who would but a few years since, when we had scarlet and black Invincible, Painted Lady, and a few others, the best not exceeding half a dozen, have imagined that close upon 100 named varieties would ever be evolved?

If any seedsman would have the courage to cut his list down to a fine selection of say twelve only, eliminating any variety on which something new was an improvement, what good service would be rendered to those wishing to buy and have the best only. Who can grow only half of ninety-five varieties, and still farther, who could make a selection from so bewildering a list? Practically it is impossible. Descriptions are florid and enticing; the reality, when seen in the flowers, is very disappointing.

At the recent meeting at the Drill Hall, with so many of these so-called varieties represented, I endeavoured to make a rather liberal selection of colours which pleased me. My tastes may be peculiar, but I prefer the selfs, and indeed, in all cases found these to be the most attractive. Some edged or flaked flowers perhaps catch on with other people, but I find the selfs most favoured. The best whites were Emily Henderson and Blanche Burpee. Either one is good, they scarcely differing. Of primrose or creamy shades, Queen Victoria and Mrs. Eckford resemble, but the former seems to have rather the finer standard. It is, however, not a specially attractive colour. Very beautiful shades of pink and carmine are Lovely, Royal Robe, Countess of Paris, and Meteor. This is one of the loveliest shades or hues found in Sweet Peas, and all the four named are worth growing. Of mauve and blue shades, New Countess, Captivation, Dorothy Tennant, and Emily Eckford are charming. Captivation is particularly beautiful, colour of a rosy blue hue.

Then of red or scarlet shades, Ovid, Cardinal, and Mars are very rich and effective; whilst of deep purple and maroon hues, Shazada, Stanley, and Duke of Clarence are of the best. In ordinary collections, however, about one of these heavy coloured varieties suffices; good blues, pinks, carmines, roses, scarlets, crimsons, and of course whites, about two shades, or slightly diverse coloured varieties of each giving a first-rate selection.

Sweet Peas need to be grown thinly, and small clumps of a few plants well staked and mulched usually give the finest flowers. The harder these are kept cut the better, but where grown specially for cutting it is well to select a site in the kitchen garden. Under any circumstances, seed pods should not be allowed to form. An early sowing may be made in pots under glass in January to plant out in April. A second should be made outdoors in April, and a third for late work early in June, as then fine fresh flowers are had for a long season.—A. D.

Rose Show Fixtures for 1897.

July 8th (Thursday).—Bath, Bedford, Farningham, Gloucester, Harrow, Newcastle-on-Tyne,† and Woodbridge.
,, 9th (Friday).—Glasgow.
,, 10th (Saturday).—Manchester, New Brighton.
,, 13th (Tuesday).—Wolverhampton.†
,, 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
,, 22nd (Thursday).—Halifax, Trentham, and Bedale.
,, 23rd (Friday).—Ulverstone.
,, 27th (Tuesday).—Tibshelf.
,, 28th (Wednesday).—Chester.*
,, 31st (Saturday).—Liverpool.*

* Shows lasting two days. † Shows lasting three days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list any further fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—Edward Mawley, *Rosebank, Berkhamsted, Herts.*

St. Mungo Rose Show.

The third annual Show of the St. Mungo Rose Society will be held in the Fine Art Institute, 175, Sauchiehall Street, Glasgow, on Friday next, when is hoped there will be a capital display of the queen of flowers. The schedule, in which twenty-nine classes are particularised, is a comprehensive one, and while the prizes are not very large, they should be sufficiently good to bring forth fairly strong competition. In and around Glasgow alone there ought to be some ardent rosarians, and it is well known that several of the nurserymen north of the Tweed can stage excellent Roses when it pleases them to do so.

Some British Roses of the Victorian Era.

The finest Roses originated by British rosarians during the reign of Queen Victoria have been for the most part of pink or crimson hue. Among the most prominent of these are Beauty of Waltham and Duke of Edinburgh, natives of Waltham and Cheshunt respectively, from which great rosariums have also come Duke of Teck, Duke of Albany, Crown Prince, Cheshunt Hybrid, Salamander; Waltham Standard, a handsome variety of recent origin, somewhat akin to A. K. Williams; Carmine Pillar, a single crimson climber of great beauty; and Princess May, described as a pale pink Gloire de Dijon.

Mr. B. R. Cant of Colchester has given us Prince Arthur, a brilliant variety, derived from Général Jacqueminot. Mr. Harry Turner has come to us from the Royal Nurseries, Slough; while to Mr. Cranston of Hereford we are indebted for Sir Garnet Wolseley and the Crimson Bedder, the former of which I regard as being quite distinct from its so-called synonyms, in which opinion I by no means stand alone; while the latter is a variety of charmingly bright aspect and exquisite fragrance, and therefore of great value for garden cultivation.

The late Mr. Henry Bennett's Captain Hayward is also a very beautiful and richly perfumed Rose. Among pink Roses of British origin the most precious are Mrs. John Laing, Marchioness of Downshire, and Mrs. Sharman Crawford, of which the last-mentioned variety, though not the grandest in dimensions, is the most graceful in habit and artistic in form. For this reason I prefer it to Mrs. John Laing.

The two most valuable white Tea Roses raised in England during Victoria's reign are Devoniensis and Souvenir de S. A. Prince, the latter of which I find more reliable than any Rose of its special colour I possess. No continental yellow Tea with which I am acquainted is superior to Medea, a superbly endowed native of Waltham Cross.—David R. Williamson.

Roses at Kew.

Anyone visiting Kew during the summer months cannot fail to admire the masses of colour produced by the groups of Roses in the "Rose garden" near the pagoda. Formerly a long cutting from which sand and gravel had been taken, it was, eighteen months ago, transformed into its present condition, and now forms one of the most popular features of the Gardens. The centre is a broad grass walk, flanked on each side with terraces and bays, the soil being kept in position by large tree butts placed roots outward.

The Roses which are used are the best flowering species, with a few of the rambling semi-double varieties; also dwarfs, such as "White Pet," which do admirably in the crevices between the tree roots. Massing is done on an extensive scale, each separate bay or terrace being devoted to a single species or variety.

Some idea of the effect produced by these masses may be gathered from the fact of twenty to thirty good-sized plants of R. lutea being planted together, seventy plants of Crimson Rambler, and so on. Rosa multiflora is made use of at the back of the butts, on the topmost terrace, where it is allowed as much room as it likes for development. A hybrid between the last named and a H.P. forms a group close to R. multiflora; it has pretty semi-double pink flowers, which are very freely produced. R. rugosa and a collection of the newer hybrids from this well-known species are to be seen. Two of the best of the hybrids are R. Blanc de Coubert, a very pretty semi-double white, with flowers as large as those of R. rugosa, and a red known under the name of Mrs. Anthony Waterer. The latter is an exceptionally vigorous grower and free flowerer, and as it becomes better known is sure to be eagerly sought after. A group of twenty or more plants may be seen at Kew.

A large group of R. spinosissima, with its many coloured single and double varieties, may be seen. Perhaps the most showy of the varieties of this species is R. spinosissima var. altaica, which grows taller and produces larger flowers than the type. Several plants of Carmine Pillar are planted at the foot of a large Holly, the dark foliage of which makes a fine background for the pretty carmine flowers. The white-flowered, dwarf-growing Japanese Rose, "Rosa Wichuriana," forms a mass on a bank; the pink-flowered R. setigera (a N. American species) makes a beautiful picture in another place; while many other equally good species and varieties are to be seen.

The plants are nearly all on their own roots, and are planted in heavy clay soil mixed with some of a lighter nature, and appear perfectly happy. Anyone wishing to grow a selection of Roses of this class cannot do better than visit the Rose garden at Kew during the summer months.—D. K.

Roses for Town Gardens.

We think we can best answer "F. W.'s" question regarding Roses for town gardens by reproducing an article from the pen of Mr. Wm. Paul which appeared in these columns a few years ago, and which will be found thoroughly reliable.

So much has been written on Roses of late that one feels it almost necessary to offer an apology for taking up the pen to add to the already abundant literature on the subject, and yet day by day we receive letters seeking information on various points in Rose culture, which show that the writers have not met with the information they stand in need of, or have failed to understand it. The most numerous queries that reach us relate to the management of Roses in and around large towns, and to that phase of the subject I propose at the present moment to give my attention.

Even in and around large towns the disadvantages which vegetable life have to contend with vary to a considerable extent. Dense smoke is not always the most inimical of these. The existence of certain chemical works filling the air with the noxious vapours they exhale are often more pernicious. We have known Roses and other plants prosper fairly well amidst dust and smoke, but succumb rapidly after the working of a manufactory of chemicals. If the latter exist extensively, and the consequences of the mischief they produce cannot be modified by scientific or other means, we fear the cultivation of Roses within their influence will give little satisfaction. But mere smoke, the smoke arising from the consumption of ordinary coke and coal, unless in unusual quantities, may be met and negatived to more or less extent by proceedings which, if costly, may yet compensate for the trouble and expense incurred.

In very smoky districts we would not recommend the cultivation of Roses otherwise than under glass. A span-roofed house, the slopes facing east and west, the top lights removeable, is recommended for this purpose. It should be heated with 4-inch pipes, and the plants may be either planted in beds or kept in pots. In districts less smoky the plants may be placed in beds or borders out of doors. As in both cases it is the pursuit of Rose growing under difficulties, no point should be missed that is likely to minimise the existing disadvantages. A good soil should be secured for them to grow in. A careful regulation of the temperature and moisture should be secured for the plants indoors, and shelter in spring and winter be provided for those out of doors. Cleanliness is in both cases very important. Not only keeping the plants free from insects by smoking or washing, but keeping the leaves free from sediments of various kinds should be sedulously attended to. A good syringe is an indispensable instrument for this purpose, and a solution of softsoap and quassia forms an excellent wash. Never allow dirt of any kind to remain settled on the leaves, nor allow any insects to rest there long enough to look upon the plants as a home.

Perhaps one of the greatest mistakes made when about to grow Roses in smoky and other unfavourable districts is in an unfortunate or injudicious choice of plants and sorts. Free-breathing Roses are wanted for smoky districts, as free-rooting Roses are wanted for heavy soils. But little attention has hitherto been paid to these distinctions, although the practical cultivator knows how important they are. First let me offer a list of sorts that appear most likely to flourish in and around large towns.

Fifty Roses for Very Smoky Districts to be Grown Under Glass.

Moss.—Crimson Globe and Zenobia.

Hybrid China, &c.—Charles Lawson, Chénédolé, Coupe d'Hébé, Paul Perras, Paul Ricaut, and Paul Verdier.

Hybrid Perpetual.—Albert la Blotais, Alphonse Soupert, Anna Alexieff, Anna de Diesbach, Baroness Rothschild, Boule de Neige, Captain Christy, Charles Dickens, Charles Lamb, Countess of Rosebery, Countess of Oxford, Crown Prince, Dupuy Jamain, Edward Morren, Elizabeth Vigneron, Ella Gordon, Général Jacqueminot, Heinrich Schultheis, Inigo Jones, Jean Rosenkrantz, John Hopper, Jules Margottin, La France, Madame Cesar Brunier, Madame Clemence Joigneaux, Magna Charta, Marchioness of Lorne, Merveille de Lyon, Mrs. John Laing,

Paul Neyron, Pride of Waltham, Ulrich Brunner, Victor Verdier, and Violette Bouyer.

Noisette.—Bouquet d'Or.

Tea-scented and Hybrids.—Cheshunt Hybrid, Climbing Niphetos, Gloire de Dijon, Madame Berard, The Bride, Sunset, and White Lady.

Fifty Roses for Less Smoky Districts for Beds or Borders Out of Doors.

Moss.—Baron de Wassenaër and Captain Ingram.

Damask.—La Ville de Bruxelles.

Alba.—Celestial.

Gallica.—Cynthie, Duchess of Buccleuch, Ohl, and Surpasse Tout.

Rugosa.—Mme. Georges Bruant.

Perpetual Scotch.—Stanwell.

Hybrid Perpetual. — Alphonse Soupert, Anna Alexieff, Antoine Mouton, Baroness Rothschild, Boule de Neige, Centifolia Rosea, Coquette des Blanches, Dr. Andry, Duke of Edinburgh, Gabriel Tournier, Garden Favourite, Général Jacqueminot, Gloire de Margottin, Glory of Waltham, Hippolyte Jamain, Jean Cherpin, La Duchesse de Morny, La France de '89, Lord Bacon, Mme. Isaac Pereire, Magna Charta, Mrs. John Laing, Paul Neyron, Prince Arthur, Princess Louise Victoria, and Prosper Laugier.

Bourbon.—Mme. Baron Veillard and Mme. Desprez, Robusta, Sir J. Paxton, and Souvenir de Malmaison.

Noisette.—Aimée Vibert, Céline Forestier, Rêve d'Or, and Wm. Allen Richardson.

Tea-scented and Hybrids.—Gloire de Dijon, Grace Darling, Pink Rover, Reine Marie Henriette, and Waltham Climber.

Thus far of sorts: we have still a few words to say with regard to the selection of plants. Above all things avoid plants that have been made tender by the employment of excessive heat. In May of this year we were in a house of young Roses where the thermometer stood at 96° in the shade at half-past six o'clock in the evening. The grower very truly said "that was the way to make them grow." But is it the way to produce plants that will flourish in the future under the ordinary conditions of plant life? We think not. What sort of men and women should we expect our children to become if in their infancy they were coddled in this manner? Again, we have heard of plants from the north of Britain recommended on the ground that "they are hardier than those brought up in the south." This is a fallacy. The ripening of the wood is, as all experienced persons know, the true test of hardiness, and the shoots of Roses are not likely to ripen better in the north than in the south. Once more, plants that are overfed for the purpose of getting large and fat flowers for exhibition, and plants that are underfed through indolence or greed of gain, are equally objectionable. Everywhere, and always, but in town gardening especially, the purchaser should look for moderate well-ripened wood when purchasing his Roses; he would do so if about to purchase Grape Vines or Peach trees, and this state of the wood is as important in the one case as in the other.—Wm. Paul, *Pauls' Nurseries, Waltham Cross, Herts.*

RYECROFT BEAUTIES.

The beauties of Ryecroft are very numerous, and extremely varied both in character and in their time of reigning. In the autumn the visitor to Ryecroft Nursery would go to see the Chrysanthemums, and be so charmed with them that he would have eyes for nothing else. On another occasion he might go to be dazzled by the glorious beauty of the decorative Pelargoniums, or the more fiery Zonal, the softer hued Ivy-leaf, the graceful Fuchsia, the charming tuberous Begonia, or the varied Petunia. In all of these lie the beauties of Ryecroft, and the visitor who goes just now will come in for a fair share of them, and acknowledge, as the writer recently did, that the time devoted to Mr. H. J. Jones' Nursery at Hither Green, Lewisham, had been well spent from an educational as well as a social point of view. Besides the hearty Mr. H. J. Mrs. H. J. was met, and if her greeting were not so boisterous as that of her husband it was none the less sincere, especially as it was followed by an invitation to an excellent tea, in which home-made Tomato jam and Tomato ketchup, with home-grown Cucumbers, figured conspicuously.

But with our French cousins let us say *revenons à nos moutons*, which being literally translated means "let us return to our sheep"—that is to say to our flowers. We may first look in at the Begonias, which, like everything else here, are grown by the thousand in long span-roofed houses. Structure after structure is absolutely filled with plants, while in frames there are more in boxes, besides several rods of ground occupied with plants, the quality of which as open-air flowers it is desired to test. It will be remembered by many readers of these notes that this grower staged a group of Begonias at the Temple Show, so that they will know to what a state of excellence the plants are brought; but well as they looked under canvas they certainly show better at home, and produce a really superb display. There one can see at a glance the characteristic growth of each variety, a thing that it is practically impossible to do at any flower show, and all gardeners recognise the importance of knowing something of every plant they are about to grow.

Though one plant will be tall and another dwarf, there is one thing in which they are all identical, and that is their health. Every one has its handsome leafage in the best possible condition, and tells plainly how well their cultivation is understood. Amongst all the thousands a weak plant was not to be seen. There were single varieties and double ones, named and unnamed, from the small one to the large, and representing all colours (except blue) from pure white to the deepest and most velvety crimson. Taken as a whole, the collection is one of the finest the writer has seen, and it is so good that everyone who can do so should make a journey to see it. It is not proposed to mention any names, either of single or double, for the simple reason that where all are of excellent quality the task of making a small selection is much too difficult, and Begonias are essentially flowers which growers should select for themselves, so as to insure getting the colours and shapes that they most admire.

From the brilliancy of the Begonia we turned to the softness of the Petunia. Of these the number of plants grown is very large, though it does not, of course, assume such proportions as the Begonias, and the range of colour is exceptionally wide, at any rate amongst the doubles which were seen. The plants, as a rule, were not of great size, but they produced flowers of exceptional beauty of form, substance, and colour. As Mr. Jones is making a speciality of them, we may hope to see some novelties of merit from this source in future years. Then there are the Fuchsias, of which a selection of upwards of three dozen named varieties, comprising both single and double, is catalogued. In addition to these standard varieties, as they may well be termed, new ones from all available sources are constantly being tried, and amongst those that were in flower when this visit was made were several that gave promise of considerable merit, either in size or colour of the flowers. These plants are deservedly becoming more and more popular for flower gardening in the summer, and Mr. Jones wisely pays special attention to their adaptability for this purpose.

The beauty and quality of the Ivy-leaved Pelargoniums at Ryecroft has been referred to in the Journal by other writers in previous years, but they deserve another word or two now. The chief points in the collections are the size of the individual flowers, large numbers of blooms to a truss, and the distinctness of the colours. In Ryecroft Surprise with its immense blooms we have one of the finest varieties in cultivation, the deep salmon pink hue of its flowers making it singularly pleasing. Superb is the new form known by the name of Achievement, which is the result of a cross between Souvenir de Charles Turner and a pure White Zonal, partaking of the characteristics of both. The short, sturdy growth is that of a Zonal, while the leafage resembles the Ivy-leaf, as do the handsome trusses of soft salmon pink flowers. It is one of the most decided acquisitions that have been placed before the horticultural world of late. Others there are of striking beauty, and of the first merit, but the two mentioned must suffice for the time being, as to do justice to the collection would mean the writing of a special article, and the description of two or three dozen varieties. Besides those in commerce there are new ones under trial, but only one or two promise to be up to the standard of excellence adopted by Mr. Jones.

Turning now to the Show, Fancy, and Decorative Pelargoniums, we find the most glorious display. The plants that have been named previously were all beautiful, but none of them approached the glorious spectacle presented by these in a large span-roofed house. The broad centre stage and the side and end stages were absolutely full of plants of all the best varieties in cultivation, and as all of them were carrying several trusses of flowers of white, pink, rose, scarlet, and crimson colours, with the intermediate shades, the effect can be imagined. There were old forms and new, small plants and large, dwarf and tall, light and dark, all placed carefully in the position where their best feature would be brought into the greatest prominence. Thus no two similar colours were brought together, but were so chosen that each assisted materially in enhancing the charms of its neighbour. Much had been heard of the Ryecroft Pelargoniums, but no idea had been formed of the magnitude and the quality of the collection, which came as one of the greatest of the several Ryecroft surprises to the writer of these brief notes, who had previously only visited Ryecroft once, and that during the reign of the autumn queen.

To speak of the varieties is a matter with which it is not easy to deal, as the average quality is so excellent. Endeavour will, however, be made to mention half a dozen only, as being amongst the cream of the whole, though a personal inspection when buying is likely to prove much more satisfactory than a selection made by another. First of all must be placed Eucharis, which everyone is sure to admire. The bloom is large, pure white in colour, and excellent for use in a cut state. Mr. H. J. Jones is the most profuse flowering variety in the whole collection, of which the colour is bright rosy red with a crimson blotch on the upper petal, while the blush white of Mrs. H. J. Jones makes, as it should do, an excellent companion. Mrs. Gordon, a lovely delicate blush, is not yet in commerce, but is certain of popularity. Mrs. W. Wright is superb. The colour in the early stages is soft rosy blush, passing to pale blush with age, while Victoria Regina, a pure white, will hold its own for some time to come. The many others of equal merit cannot now be named for the simple reason that all are excellent, and one cannot therefore choose.

It is now time to draw these notes to a close, though mention has not been made of all the beauties of Ryecroft. Some day in the future another invitation may be forthcoming, which will, unless something very extraordinary occur, be promptly accepted, for the kindness of Mr. and Mrs. Jones is not likely soon to be forgotten by—Stranger.

Notes & Gleanings

EVENTS OF THE WEEK.—For the events of horticultural interest to be held during the forthcoming week we call the attention of readers to the list of show fixtures that will be found on page 23. The Committees of the Royal Horticultural Society are to meet in the Drill Hall on Tuesday next.

—— THE WEATHER IN LONDON.—The heat in the metropolis of late has been very oppressive. The temperature may not have been so high as we have had it, but lack of air has made the atmosphere very close. There have been winds occasionally at night, but practically no rain has fallen for several days. At the time of going to press on Wednesday it was bright and warm.

—— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, July 13th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "Mutual Accommodation between Plant Organs," will be given by the Rev. Prof. Geo. Henslow, M.A., F.L.S., at three o'clock.

—— SOUTHAMPTON SHOW.—The Royal Horticultural Society of Southampton will, as usual, hold its annual exhibition at Southampton Common, on July 31st, and August 2nd (Bank Holiday). It is regrettable to learn that the Council has had, owing to financial difficulties, to curtail its prize list, which remains, however, a very good one. There are classes for plants, flowers, fruits, and vegetables, the total number being eighty-eight. Notwithstanding the necessary slight reductions we trust the show will prove to be an excellent one, and receive such support as to bring financial matters on to a sounder basis, when the Council would doubtless at the next show offer the same generous privileges as it has done in previous years. Mr. C. S. Fuidge, "Heckfield," 17, New Alma Road, Southampton, is the Hon. Secretary, to whom all communications should be addressed.

—— HAILSTORMS.—On Thursday, 24th June, hailstorms of terrible violence occurred throughout Essex, Middlesex, and parts of Hertfordshire, doing severe damage to glass houses on over sixty nurseries at Chelmsford and district, Ponders End, Enfield, Enfield Highway, Waltham Cross, Hellesden, and Harrow; 21-oz. glass of all sizes was completely riddled, and considerable damage was done to the Grapes, Cucumbers, Tomatoes, and all kinds of plants and Ferns. We are glad to hear that thirty nurserymen who suffered loss were insured with the Nurserymen, Market Gardeners', and General Hailstorm Insurance Corporation, of 2, King Street, Covent Garden, who immediately assessed the damage done and paid the claims six days after. One nurseryman lost 70,884 square feet of 21-oz. glass, and his claim at 3d. per square foot amounted to £886 1s.

—— NATIONAL CHRYSANTHEMUM SOCIETY'S ANNUAL OUTING.—I have the pleasure to inform you that the annual picnic and outing will take place on Monday, July 19th. The members will travel to Henley-on-Thames by Great Western Railway, and launches will be waiting at the Royal Hotel landing stages to convey them to Greenlands, the residence of The Hon. W. F. D. Smith, M.P. Dinner and tea will be provided in a spacious marquee in the grounds, and during the afternoon there will be an excursion down the river, returning to Greenlands for tea. Ladies are specially invited. The charge for the day—including return fare from Moorgate Street and Paddington to Henley and back, launches, with dinner and tea—will be 10s. to members, and 11s. to non-members. Members not using railway tickets, but joining the party at intermediate stations, or at Henley, will pay 7s. 6d., and non-members 8s. As this is certain to be a highly popular trip, combining delightful grounds and gardens, with a water journey on the Thames, early application must be made for tickets, so that the necessary arrangements may be made, more especially in reference to ample accommodation by rail, and for dinner and tea. Members requiring tickets from Moorgate Street, which will be available from any intermediate station to Paddington, must state this on application, and they can alight either at Praed Street or Bishop's Road for Paddington. —RICHARD DEAN, *Secretary*, *Ealing*.

—— GARDENING APPOINTMENT. — Mr. J. Roberts, formerly gardener to the late Baron Lionel de Rothschild, Gunnersbury Park, has been appointed head gardener to the Duke of Portland, Welbeck Abbey, in place of Mr. Horton, who is retiring.

—— BOTANICAL SOCIETY FOR PERTH, WESTERN AUSTRALIA.—A botanical society has recently been established at Perth, West Australia, and has been given the designation of the Mueller Botanic Society, as a tribute to the memory of the late Baron von Mueller, who spent the best part of his life in investigating the plants and other products of Australia. Sir John Forrest has been elected President of the new Society, Mr. Wittenoom and Mr. Leake Vice-Presidents, and Mr. Skews Secretary.

—— PREPARING PEARS FOR MARKET.—It is said that the finer class of Pears are much more profitable when each fruit is wrapped separately in paper than when packed, as fruit is generally packed, in barrels. Just how this causes a better preservation of their flavour, says "Meehan's Monthly," is not known, except on the general principle that Pears ripened in the dark are always better in flavour than those exposed to the light; and the paper probably adds to the exclusion of the light.

—— SPRAYING.—At the beginning of a useful bulletin on spray-pumps and spraying, just issued by the New York Experiment Station, is the following important notice:—Do not spray trees and plants when in bloom. It is in no instance necessary or desirable. Not only is this practice liable to injure the delicate parts of the flower, but, what is even more important, it poisons the bees and other insects that are our friends. It would be impossible to grow some of our fruits in commercial quantities without the aid of insects in fertilising the blossoms.

—— THE INTRODUCTION OF LILIUM AURATUM.—I should like to correct an error into which I appear to have fallen with regard to the first blooming of this grand Lily. The error arose not from a lapse of memory, for I have believed in my statement for the last thirty-five years; but Mr. Harry J. Veitch has kindly written to me to say that it first bloomed with the Chelsea firm, and not with Mr. Standish. How I came to have made the mistake I do not know, but, as I have said, ever since the opening of the Royal Horticultural grounds in South Kensington the impression has remained on my mind. Mr. Veitch says that there was a great race between his brother, Mr. John Gould Veitch, and Mr. Robert Fortune as to who should be first in the field, and that his brother won the race.—D., *Deal*.

—— FREAKS OF TOMATOES.—I was recently looking through an enthusiastic amateur's collection of Tomatoes when I noticed two plants behaving in a very unusual manner. Out of some sixty showing every indication of proper cultural requirements, two had just made six leaves, and instead of growing in the ordinary way they are both crowned with an enormous truss of bloom. On one plant I counted twenty-four fruits just set and thirteen expanded blooms. The other is not quite so large. The plants are all growing in 10-inch pots, and, with the exception of these two, are from 3 to 4 feet high. The kind grown is Sutton's Main Crop. It would be interesting to know if any of your readers have had similar experience, either with the above named or any other variety.—J. C., *Lancashire*.

—— ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—The monthly meeting of the above Association was held at Shanklin on Saturday, July 3rd. Dr. J. Groves, B.A., presided. A thoroughly practical paper on the cultivation of Gloxinias was read by Mr. N. Jolliffe, Woodside Gardens, Wootton, who dealt with the history, propagation, and general treatment. The exhibits were numerous and of excellent quality. Messrs. J. Peed & Sons, Upper Norwood, staged Gloxinias and Streptocarpus; Messrs. J. H. and M. Silsbury, Shanklin, a fine collection of Violas and Cannas; Mr. W. J. Hayles, F.R.H.S., Wootton, Poppies; Mr. F. Silsbury, Shanklin, a stand of twelve Roses; Mr. J. H. Perkin, gardener to G. W. Drabble, Esq., Los Altos, Sandown, Gloxinias and a dish of Polegate Tomato, for which he received the Association certificate of cultural merit; Mr. W. W. Skeath, gardener to Miss Mitchell, Macrocarpa, Ventnor, a fine collection of seedling tuberous Begonias (single and double), for which he received the Association certificate of cultural merit; and Dr. Morgan of Woodside, Wootton, a huge Gloxinia. The members are having an excursion to Brooke House, the residence of Sir Chas. Seeley, Bart., on the 14th of July. It was decided to still further extend the interest of Island horticulture by awarding the Association certificate of cultural merit to the local shows for the best exhibit in each show. Several new members were elected, which brings the total number on the books to 161.

—— JUNE WEATHER AT HODSOCK PRIORY.—Mean temperature, 59·5°. Maximum in the screen, 82·4° on the 13th.; minimum in the screen, 37·2° on the 10th; minimum on the grass, 30·1° on the 10th. Sunshine, 136 hours, or 27 per cent. of the possible duration. Rainfall, 2·76 inches. Rain fell on sixteen days. A very mild month, especially at nights. Heavy showers at times, and some very stormy weather in the third week.—J. MALLENDER.

—— WEATHER IN SOUTH WALES.—The following is a summary of the weather here for the past month:—Rainfall, 3·81 inches; maximum, 0·98 on the 8th. Rain fell on twelve days. The wind was in the W. and S.W. on twelve days, and in the E. and N.E. on seven days. There were seven sunless days. Highest reading, 92° on the 3rd; minimum, 37° on the 1st. Average maximum temperature, 69·9°; minimum, 47·6°.—WM. MABBOTT, *Dowlais*.

—— JUNE RAINFALL AT HAYWARDS HEATH.—The total rainfall at New England Road, Haywards Heath, Sussex, for June was 2·09 inches, being 0·29 inch above the average of the district. The heaviest fall was 0·72 inch on the 8th; rain fell on eight days. The maximum temperature was 87° on the 11th, 12th, and 24th; the minimum 43° on the 17th. Mean maximum, 75·08°; mean minimum, 51·26°. Mean temperature, 63·17°, which is 3·12° above the average of nine years.—R. I.

—— THE WARMING OF RESIDENCES.—It may at the first glance perhaps be thought that the subject indicated is somewhat unseasonable now, but a moment's reflection will satisfy that it is not. For averting discomfort and ill health in winter, the result of excessive cold, action should be taken in the summer, so that all may be in readiness when the time of trial comes. Recognising this, Messrs. Richardson & Co. of Darlington have published what they modestly term "a few suggestions." Very good suggestions they are, and conveyed in attractive guise—namely, photographic illustrations of private residences and public buildings which have been made proof against excessive cold in a safe and effective manner, a matter which has not received the attention it deserves in this country.

—— ANCIENT SOCIETY OF YORK FLORISTS.—The eighteenth annual Chrysanthemum, fruit, and vegetable show of this Society is to be held in the Fine Art Exhibition Building, York, on November 17th, 18th, and 19th, when it is anticipated there will be an admirable display. In the schedule now before us we see that there are fifty-six classes devoted to Chrysanthemums, in some of which the prizes are excellent. For example, in the class for thirty-six Japanese and eighteen incurved, distinct, prizes of £10, £5, £3, and £2 are offered, while to the first is added the "Citizens' Challenge Prize" of the value of £20. A gold medal and £10 are offered for the best group of Chrysanthemums arranged for effect with the aid of foliage plants in a space not exceeding 120 square feet, while a gold medal and £8 will be handed to the exhibitor who stages the best group of Chrysanthemums alone, "cultural excellency only to be the basis of merit." There are thirteen classes for fruits and twenty-seven vegetables, in all of which substantial prizes are given. The hardworking Secretary is Mr. E. Lazenby, 13, Feasegate, York, from whom schedules and full particulars may be had on application.

—— SCORPION AND FLOWER.—One evening last February, while sitting in the verandah of my house at Aden, my attention was drawn to an object advancing across the floor, which seemed to be some peculiar leaf, insect, or phasma. On looking at it closer I saw it to be a scorpion (identified by Mr. Pocock from my description as Parabuthus liosoma), which was holding over its back by one claw a large blossom of Poinciana regia, known in Aden as the White-gold Mohur tree. Its tail, curled over its back, further assisted in retaining the flower in position. The nearest tree from which it could have been obtained was at least 30 feet away, and to bring it the scorpion must have carried it over a low stone parapet and up two or three steps, so that intention seems to be proved. What that intention was it is hard to define. Hardly for concealment, for the size of the flower made it more conspicuous; besides, it was night. If it was the lamp light it wanted to avoid, it is necessary to assume that, finding the light too strong, it went back to get the flower. It could hardly be as food, for scorpions are not known to live on vegetable substances; nor, as far as I know, do they construct nests. I regret that I did not allow the creature to reach its destination, and so ascertain its intention; but, unfortunately, I gave in to my first impulse and crushed it. My wife, adds the writer, suggested that perhaps it was going to a wedding, but this explanation is more poetical than scientific.—A. NEWNHAM (in "Nature").

—— PINK ALBINO.—The Pink shown under this name by Mr. J. Lamb, Burton Joyce, Notts, at the last meeting of the Royal Horticultural Society, differed from the other white varieties in having smooth Carnation-like petals. The raiser now sends us a few blooms for inspection, saying, "It is a good grower, free bloomer, and forces well." The flower is one of much beauty, and with such desirable attributes as those mentioned should secure considerable popularity. The Floral Committee of the R.H.S. recommended an award of merit.

—— SHRUBS FOR LIVERPOOL.—A departure, which might well be copied by other local authorities, has recently been adopted by the Parks and Improvement Committee of the Liverpool Corporation. A number of shrubs grown in large tubs have been placed round the base of the Wellington column in that town, and it is understood that a considerable number are to be placed in other prominent and appropriate spots in the city. Nearly all our large towns have bare uninviting spaces, that might be made much more attractive by the use of tubbed plants.

—— REDUCTION IN POSTAGE.—The reductions that have been made in the rates of postage will have much effect on the pockets of flower senders. The rate for letters is now a halfpenny for 2 ounces throughout, subject to the condition that no letter will be charged less than a penny. The new parcel post rate is 3d. for the first pound, and 1d. for each subsequent pound, with this modification—that the tenth and eleventh pounds are carried together for 1d. There is now no charge for the delivery of telegrams at any place within three miles of post office. For larger distances than three miles the charge for delivery, commencing at 1s., will proceed at 3d. per mile.

—— LAWS AGAINST WEEDS.—A bulletin just issued by the United States Department of Agriculture goes to show that in twenty-five of the States of the Union laws are in force—or at all events in existence—with the object of putting down the growth of weeds. In some cases, as in California, Delaware, and Kentucky, the law is directed against only a single species, usually the notorious Canada Thistle. Other States, such as Minnesota and Ohio, prescribe as many as fourteen species of weeds. The Canada Thistle is on the black list in twenty-one out of the twenty-five States, whilst six States legislate against the Russian Thistle. Despite its name, the Canada Thistle is an introduced plant in North America. It is, indeed, says a contemporary, a native of Britain, where it is known as the Creeping Thistle (Carduus arvensis). It grows to a height of from 2 feet to 4 feet, and possesses dingy purple flowers, with a more or less cottony stem. There is, as a matter of fact, no commoner Thistle in Europe and Asia, whence it has accompanied cultivation to all parts of the world. The so-called Russian Thistle is not a Thistle at all. It is a member of the natural order Chenopodiaceæ, to which the Mangold, Beet, Spinach, and Good King Henry belong.

—— HARDY FLOWERS.—"A Talk about Hardy Flowers" was given to an average attendance of the members of the Wakefield Paxton Society on Saturday, June 26th, by Mr. John Wood of Kirkstal Nurseries. Major Taylor presided, and Mr. John Burton was in the vice-chair. The address was both instructive and interesting. Mr. Wood decided to ignore the paper he had written, and after a few preliminary observations, proceeded to explain a number of plants he had brought with him, as well as flowers and leaves of others which he grows, concluding by naming a number of specimens which were brought by members. It seemed strange, he said, that hardy plants should have got shirked and left in the rear so far, making an apology almost necessary for their introduction into the modern garden. He often heard gardeners object to hardy flowers because either they had the wrong sorts or had put them in the wrong places. They must not be in too conspicuous a place. In a large garden they could have a large variety at will, but in a small garden the selection must be choice and carefully made. Style was the leading idea with many, and in certain places it was necessary, but he thought it was carried too far. If they went into the hardy or Alpine mode of gardening they would find that they could not practically go on with style because this mode was something that could not be copied, inasmuch as there was such difference in soil, climate, and environment to contend with. In the case of Geraniums and Petunias, for instance, they could go on repeating them anywhere with a green foil, but before planting such kinds as he had there they must study their habitat ere they planted them, and to be interested in them they must know them. There were about 3000 species and varieties of hardy plants, including the florist's varieties. The lecturer then handed round to the company the specimens he had brought, giving their common and botanical names, and explaining their habitat.

—— Woodlands Vale, Ryde.—This beautifully situated mansion is the residence of Lieut.-General Somerset John Gough Calthorpe, Chairman of the Isle of Wight County Conncil. The extensive gardens at Woodlands Vale are in the capable hands of Mr. W. Heath. Peaches, Nectarines, and Grapes under glass promise well both for quantity and size; Melons and Cucumbers have been yielding abundantly; the kitchen garden crops are in the pink of condition. Amongst the many varieties of Peas grown Sutton's Excelsior has given entire satisfaction, and merited a permanent place in this garden. It is of dwarf habit, free bearer, fills well—two or three pods I opened each had six to eight peas in—colour and flavour realise expectations. Apples and Pears are about average, with extra crops of Strawberries, Gooseberries, Currants, and Figs. Amongst the many varieties of Strawberries grown Mr. Heath speaks very highly of Royal Sovereign, and is propagating it very largely. In the flower garden a magnificent show of Roses is to be seen; whilst a judicious admixture of bedding plants, including Geraniums and Lobelia, gives a charming effect to the whole place. —S. H.

—— Packing Cut Flowers.—Light wooden boxes from 3 to 5 inches deep are much better for packing cut flowers than pasteboard boxes. With the least rough handling, especially if they are in a damp condition, the latter may become crushed and the flowers spoiled. Having selected a suitable box, place a layer of sheet wadding in the bottom, seeing the corners are nicely fitted, and over this place waxed paper. Allow the flowers to stand in water for some time before packing, and when the stems have taken up all the water that is possible, lay them in smooth even rows on the waxed paper. Let the stems of the npper row meet the blossoms of the lower, and continue packing close until the box is full. Then lay another piece of waxed paper over the top, with a layer of sheet wadding next to the lid. It is of the greatest importance to have the box packed full. If the flowers do not quite fill it see that the spaces are filled with the wadding. If Roses are to be sent do not select the full-blown ones, but firm, half-opened buds. It will not be necessary to sprinkle them with water if the stems have absorbed a quantity of moisture; being covered closely from the air, they will not wither as they would if exposed.

—— Emigrants' Information.—The July circnlars of the Emigrants' Information Office and the annual penny handbooks show the present prospects of emigration. This is the best season of the year for work in Canada; but there is no demand for anyone except farmers with capital and experienced farm labourers. With regard to Victoria, a correspondent writes from Horsham—which is the centre of a large Wheat and wool district—"any hardworking, earnest man need have no fear of obtaining work; good workmen are sure of constant work." In South Australia the drought is very severe, and there is no demand for more hands in that colony or in Queensland. In Western Australia there continues to be a good demand for mechanics and farm labourers. In New Zealand large areas of some of the best lands in the North Island are being acquired by the Colonial Government from the natives for purposes of settlement, and there are good openings for farmers with a little capital. Large numbers of persons continue to arrive in Cape Colony from England and Australia, and many find much difficulty in getting work. In Natal, the Immigration Restriction Act, which has just been passed, prohibits the landing in Natal of the following persons amongst others—(1) any one who cannot himself write out and sign, in the characters of any langnage of Europe, a prescribed application form of admission giving his name, address, and business; (2) of anyone who is a pauper or likely to become a public charge; and (3) of anyone who, not having received a free pardon, has within two years been convicted of a felony or infamous crime or misdemeanour involving moral turpitude, and not being a mere political offence. Otherwise this Act in no kind of way interferes with the landing of respectable immigrants.—*Emigrants' Information Office*, 31, *Broadway, Westminster*.

CANTERBURY BELLS.

Canterbury Bells form bright, showy and effective plants in shrubbery and herbaceous borders, and might well be employed for giving a furnished appearance to positions where many other plants that bloom at a similar period would not succeed. I have seen very floriferous specimens growing and flowering freely on steep banks overhung with trees. The plants had become established when the foliage was absent from the trees, or probably they were self-sown.

Freqnently Canterbury Bells spring up in places qnite unexpectedly, and snccеed in what would be considered unsuitable positions. When in bloom they look charming in wild or semi-wild spots, and they are none the less welcome in the cultivated portions of gardens, provided their presence does not interfere with the permanent occupants. The predominating colours of Canterbury Bells are blue, lilac, rose, and white. A border containing a mixture is therefore interesting, especially as the blue, lilac, and rose vary more or less in depth of tint or shade. Double forms may be had by the careful selection of seed, but plants bearing single flowers are always produced as well as double.

The finest plants are produced from seed sown in May and June, transplanting in good soil and a favourable position so as to become strong for final planting in autumn. July, however, is not too late to sow seed in a moist position in the open, or in boxes. Transplant the seedlings as soon as possible; if this can be done to a permanent position all the better. The plants will be sure to flower, though they may not attain to as large size as earlier raised examples. Seed sown later than this month cannot be depended upon to produce plants of sufficient strength to flower the following year. Such would, however, form superb specimens the succeeding year.

The flowers are very useful for cntting, being borne on fairly long stalks. Branches of various size containing a number can also be cut. Small plants, when they do bloom before they have attained strength, are very useful in affording material for cutting, so that it is not always necessary to spoil good specimens.—E. D. S.

BARFORD HILL.

Horticulture is conducted with spirit at this the Warwickshire home of C. A. Smith-Ryland, Esq., who, in conjunction with Mrs. Smith-Ryland, takes the greatest interest in all matters connected with gardening. During the last two years a fine collection of Malmaison Carnations has been got together, and at the present time they make a grand display. About 700 plants are grown, these being chiefly the bright pink kind known as Princess of Wales. About half the number are two-year-old plants in 8, 9, and 10-inch pots. These occupy a couple of span-roofed houses. The plants have been kept very cool throughout by the admission of abundance of air both night and day whenever the temperature has been well above freezing point. The result is strong vigorous plants, carrying large, well coloured flowers, which are used in large quantities for house decoration.

Few gardens are so well supplied with these lovely Carnations as to be able to use them largely for such work, but at Barford Hill a table filled with vases is sometimes decorated solely with Malmaisons, and the necessary greenery added. Early plants have already been layered in frames, and with his usual energy Mr. R. Jones, the enthusiastic gardener, is setting about the task of providing a still larger stock of plants for next season. In the Orchid houses the plants were in superb health; indeed, I question if a more healthy and vigorous collection of cool house ones could be met with in Britain. The floor of the house, instead of being made of the usual non-absorbent materials, is formed with clean loose gravel, which keeps the atmosphere in a cool moist condition; and to this fact, as well as cultural skill, is perhaps due the fine condition of the plants. Many good forms of Odontoglossums were to be seen, some with enormous spikes and others with large and well-marked individual flowers. In the Cattleya house the bulk of the flowers were over, but the fading blooms on one large and valuable plant showed that when in full beauty the sight must have been a grand one. As no notes were taken it would be difficult for me to enumerate the many good things grown; suffice it to say that the collection contains many splendid varieties of acknowledged repute, as well as promising imported ones, the condition of all showing that their culture is thoroughly understood.

Another notable featnre in the plant houses was a fine display of Hydrangea hortensis. Few things at this season are more useful and showy for decorative purposes when grown as they are at Barford Hill. Old plants in large pots were bearing numbers of grand flowers of a clear pink colour; but something more surprising still was the gigantic trusses small plants in 4 and 5-inch pots were carrying. Some of these were fully 12 inches in diameter, which is surely no mean cultural achievement; but in one instance even this was surpassed, for a plant growing in a pot 4½ inches in diameter carried four flowers, the central one being scarcely less than a foot in diameter and the other three were of large size.

Such results prompted me to inquire about the system of cultnre followed, which was readily given as follows:—Good firm cuttings are inserted in 3-inch pots the last week in June, the soil consisting of three parts fibrous loam and one of leaf soil, with a little sharp sand added. This is pressed very firmly. When rooted the young plants are fully exposed in the open air till the autumn, when they are placed in a cool house, and kept rather dry throughout the winter to prevent the buds from starting. In February more water is gradually given, and when growth is proceeding freely a shift is given into 5-inch pots, substituting a little well decayed manure for leaf soil, and ramming the compost quite firmly. From this time the plants give but little trouble till they are in flower. They are simply kept near the glass in cool houses, receive water when they need it, and are occasionally given a sprinkling of artificial manure. This short outline of the simple means taken to secure such fine results will, I feel sure, be useful to many Journal readers.

Calceolarias, Gloxinias, Show Pelargoniums, and stove plants are all grown largely and well. In the vineries both young and old Vines promise to give very satisfactory results, while the crops in the kitchen garden show evidences of a master's hand. In these brief notes I have not attempted to give more than a passing notice of a few of the good things to be seen in this garden of Shakespeare's county. At some fnture time I hope to deal with the fine ornamental grounds.—Wanderer.

CAMPANULA GRANDIFLORA MARIESI.

"FLOWER GARDENER" is quite wrong in supposing that Campanula grandiflora Mariesi is a new plant. On the contrary, it was introduced into this country somewhere about fifteen years ago. Some seasons ago Messrs. Paul & Son, Chesbunt, received for it a first-class certificate, and as we sketched the plant at the time we give the block now for our correspondent's benefit, and that of the many others who will be interested. The plant, also known as Platycodon grandiflorum Mariesi, is exceedingly beautiful, and worthy of extended cultivation.

As shown in the illustration (fig. 5) the plant is dwarf in habit, being not more than 6 inches in height. The flowers are large and broad, measuring 3 inches or more in diameter, and of a brilliant purplish blue colour with darker veins. It is a charming plant, and deserves a better fate than it hitherto has had.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE, JUNE 29TH.—Present: Mr. McLachlan (in the chair); Rev. W. Wilks, Prof. Church, Dr. Bonavia, and Rev. G. Henslow, Hon. Sec.

Romneya, diseased.—The following report was received from Kew upon the specimens sent to the last meeting:—"The disease is caused by an obscure organism, considered by Prunet as a species of Cladochytrium. A preliminary notice is given in 'Comptes Rendus,' October 1st, 1894. The detailed account there promised is not yet to hand."

Grapes attacked by Glæosporium.—With reference to the examples sent to the last meeting, Mr. Malcolm Dunn writes, after inspecting the Vine houses at Auchterarder House, that "the vinery is of the usual 'lean-to' form, well heated and ventilated, with everything in good order for growing healthy Vines and first-rate Grapes. The Vines comprise some six or seven varieties, but only Black Hamburgh suffers to a serious extent from the disease; although it could be detected on a few berries of Foster's White Seedling, and still fewer of Alicante. As far as I can remember Muscat of Alexandria, Lady Downe's, Madresfield Court, Gros Colman, and one or two others were not affected, although intermixed with the Vines attacked. The Vines are all in vigorous health, and bearing a fine crop of splendid bunches of Grapes. With regard to the treatment they were receiving I saw nothing to which I could object."

Harpalus ruficornis attacking Strawberries. — Mr. McLachlan showed specimens of this beetle, which belongs to a carnivorous family. Its prevalence in Strawberry beds is probably caused by the presence of the litter. That it will attack Strawberries has been known for the last ten years, and that it has destroyed entire crops. As it is nocturnal in its habits, it must be looked for at night, for it lives in the soil.

CHISWICK, JULY 1ST.

A meeting of the Fruit and Vegetable Committee was held on the above date. Present: Mr. G. Bunyard (Chairman); the Rev. W. Wilks, Messrs. G. Sage, A. F. Barron, J. Smith, W. Pope, J. Veitch, R. Fife, A. H. Pearson, J. Hudson, and A. Dean.

The attention of the members was first drawn to a large collection of Peas growing in one part of the gardens. With these were several high-class varieties of established reputations, grown to give comparisons. Of the fifty-four assumed new varieties nothing of special excellence was found, general average quality being below that of last year. It is very evident that Peas are now so good it is very difficult to find new ones superior.

The awards at Chiswick are progressive, two marks representing a commendation; three marks, high commendation; award of merit, very high commendation; and first-class certificate, superior excellence. Two marks only were given to Saccharine, a nice-looking 4-feet Pea, having long green pods, the peas sugary and tender; to Harbinger (Dickson & Co.), an early free-cropping variety, pods of medium length; and Parchment, one of the sugar section from Vilmorin & Co. The pods are of medium size and pleasant eating when cooked whole.

A few stocks of Broad Beans were seen, and an award of merit was given to Dobbie's Champion, a good cropper of the long-pod section; and three marks were given to Exhibition Long-pod, from R. Veitch & Sons, and to Robin Hood, green long-pod, from Harrison and Sons. These were capital stocks. Attention was drawn to a very neat compact Cabbage Lettuce, Continuity (Daniels & Son), rather dark coloured and standing remarkably well, but no award was made.

The large breadth of trial Strawberries was next seen. These generally were in admirable condition, although some relatively were much heavier croppers than others. An award of merit was made to Wonderful, which carries a great crop of long tapering scarlet fruits of excellent flavour. Such varieties as Royal Sovereign, President, Edward Leforte, Auguste Rousselot, Countess, Latest of All, and a few others so good last year were again in capital condition; and of heavy fruiters Newton Seedling and Acquisition were marvellous examples, although the fruits are not of the best. Admiral and G. Wythes, new varieties on yearling plants, showed considerable promise.

A couple of Melons were placed before the Committee, both fair, but neither of any special merit. Mr. A. J. Ward, one of the Richmond Corporation allotment holders, sent dishes of Maincrop, Eureka, Gradus, Stratagem, Daniels' Alderman, and the Daniels' Peas, all very fine, Alderman being exceptionally so; also a good sample of Bunyard's Exhibition Bean. A cultural commendation was awarded.

ROSE SHOWS.

WEST OF ENGLAND (HEREFORD).—JUNE 28TH.

THIS old Society celebrated its thirty-first anniversary on Tuesday, June 29th, with a success which ought to have been expected on so memorable an occasion as our Most Gracious Majesty's Diamond Jubilee. Then, if ever, should be held the *fête* day of the loyal lieges of the queen of flowers, the historic national emblem, dear to the heart of every Englishman.

Doubtless in nearly every garden in the land the Rose still is far the most popular of flowers, and holds royally the pride of place. Nevertheless, it is a sad fact, introducing a problem that has to be solved, that Rose shows *pur et simple* have ceased to attract the general public, either by their presence as paying spectators or by their contributions as competing exhibitors. Numbers of Rose shows have ceased to exist, while others are in a moribund condition. The Rose Society, whose last meeting it is my privilege to report, for the last two years has contracted an adverse balance of over £50, and has failed in other ways to obtain public support.

The managers, fully realising their position, as sensible men naturally do when their pockets are appealed to, have made a supreme effort to clear off the adverse balance, and to carry on the oldest Rose exhibition in the kingdom by supplementing its special attractions by others more up to date and practically indispensable. Two short concerts and two short commediettas of half hour each were the sources of diversion introduced in the Shire Hall, and proved highly successful, while, quite as important, exhibitors from far and near, almost 250 in number, were present in great form, and six (out of eight entering) seventy-two varieties were staged, which pleasantly brought back memories of the good old times of our western Rose show. Messrs. A. Dickson & Sons especially exhibited splendidly, while their seedlings, mostly H.T.'s, were admirable, and likely to be most valuable and permanent additions both in the garden and exhibition boxes.

The Roses at Hereford were grown in Messrs. A. Dickson's gardens near Ledbury, speaking volumes as to the natural capacities of the soil and the skill and attention of Mr. Drew, the firm's able manager.

In division I., nurserymen, Messrs. Alexander Dickson & Sons, Newtownards, Co. Down, Ireland, were easily placed first, the Judges being unanimous as to the excellence of their exhibit, indeed there was not the slightest suspicion of a weak corner, so level and fine a collection of blooms being seldom staged. Very noticeable was the number of seedlings, almost up to date, exhibited by the firm, of most of whom, as has already been said, it may safely be prophesied, from their distinct colour and good habit, a permanent position among exhibition varieties. A few remarks are appended to varieties of transcendent merit. H.P. Killarney (seedling, very clear white), H.P. Exposition de Brie, H.T. Danmark (fine), H.P. Marie Baumann, H.P. Clio, H.P. Alphonse Soupert, H.P. Marchioness of Downshire (grand), H.P. Capt. Hayward, H.T. Kaiserin Augusta Victoria (splendid everywhere), H.P. Duchess of Bedford, H.P. Mrs. C. Grahame, seedling (first-rate promise), H.P. Ulster, seedling (fine substance), H.P. Merveille de Lyon, H.P. Star of Waltham (magnificent), H.P. Duchess of Vallambrosa, H.P. François Michelon, H.T. Lady Mary Fitzwilliam (finely shown), H.P. Ulrich Brunner, H.P. Her Majesty (quite a Diamond Jubilee bloom), H.T. Marquis Litta (useful colour), H.P. Gustave Piganneau, H.P. Madame Eugénie Verdier, H.P. Earl of Pembroke, H.P. Madame Gabriel Luizet, H.P. Heinrich Schultheis, H.T. Mrs. W. J. Grant (fine shell petals), H.P. Dupuy Jamain, Tea Rubens, H.P. Mrs. John Laing, H P. Charles Darwin (superb colour), H.P. Helen Keller (fine), H.P. Mrs. R. G. Sharman Crawford (superior to Clio or Mrs. John Laing), H.P. Victor Hugo, H.P. Robert Duncan, H.P. Etienne Levet, H.P. Bessie Brown, H.T. Souvenir de President Carnot, H.P. Prince Arthur, H.P. Victor Verdier, H.P. Charles Lefebvre, H.P. Ellen Drew (fine), H.P. Comtesse d'Oxford, H.P. Pride of Waltham, H.P. Comte de Raimbaud, Tea Madame Hoste (lovely), H.P. Horace Verdier (superb), Tea Souvenir de S. A. Prince, H.P. Louis Van Houtte, H.P. Mrs. E. Mawley, seedling (very high centre, promising), H.P. Tom Wood, H.P. Madame Rothschild, H.P. Marie Verdier, H.P. Marchioness of Dufferin, H.P. Countess of Caledon (great acquisition, seedling), H.P. A. K. Williams (perfect), H.T. Caroline Testout, H.P. Général Jacqueminot (not cashiered yet), H.P. Margorie, seedling (very good), H P. Jeanie Dickson, Lady Clanmorris (light seedling, good), H.P. Marquise de Castellane, H.P. George Mazarette (seedling, globular, fine), H.P. Lady A. Hill (very distinct), H.T. La France, H.P. Mons. Noman, H.P. S. M. Rodocanachi, Tea Ernest Metz, Tea The Bride, H.P. Dr. Andry, H.P. Le Havre, Tea Madame Anna Ollivier.

The second prize was equally divided between the two celebrated Colchester firms, B. R. and F. Cant (although as a rule the precedent is bad), as the character and general excellence of the blooms, in the opinion of the Judges, were indistinguishable. H.P. Helen Keller H.P. Charles Lefebvre, and H.P. Xavier Olibo in F. Cant's, and H.P.'s Dukes of Connaught and Teck, and H.T. Caroline Testout in B. R. Cant's collections were specially worthy of notice.

For thirty-six varieties, first prize Messrs. Townsend & Sons, Worcester; second prize Mr. George Prince, Oxford; third prize Mr. S. Treseder, Cardiff. For twenty-four trebles (to which a list of the first prize is appended as being of superlative excellence, if room can be allowed) fell to Messrs. A. Dickson. The varieties were H.P. Gustave Piganeau, H.T. Kaiserin Augusta Victoria, H.P. Ulrich Brunner, H.P. John Laing, H P. Star of Waltham, H.T. Mrs. W. J. Grant (superb), H.P.

Horace Vernet, H.T. Mrs. C. J. Grahame (promising seedling) H.T. Ulster (seedling of great substance), H.T. Lady Mary Fitzwilliam, H.P. Helen Keller, H.T. Souvenir de President Carnot, H P. Heinrich Schultheis, H.P. Margaret Dickson, H.P. Etienne Levet, H P. Bessie Brown (seedling), H.T. Countess of Caledon (perfect), H.T. Marquise de Litta (useful colour), H.P. Charles Lefebvre, H.T. Majorie, H.P. Duchess of Bedford, H.P. Madame Gabriel Luizet, H.P. A.K. Williams (exquisite), H.P. Madame R. G. Sharman Crawford. Mr. B. R. Cant second, and Messrs. F. Cant & Co. third.

Division II. Amateurs (open).—Class 4, twenty-four varieties.—First prize Mr. Conway Jones, Gloucester, with an admirable collection, including Noisette Maréchal Niel, H.P. Louis Van Houtte, H.P. Comtesse Oxford, H.P. Charles Lefebvre, H.P. Duchess of Morny, and H.P. François Michelon. Second Dr. Budd, Bath, including a splendid (splendid), Madame E. Lambert, Alba Roses, Ernest Metz, La Boule d'Or, Miss Ethel Brownlow, The Bride. Second prize, Messrs. Frank Cant & Co., who staged grand blooms of Cleopatra and Madame de Watteville ; and third prize, Mr. Stephen Treseder.

In the open classes for any light Rose (one sort), H.P., Messrs. A. Dickson took the prize with Mrs. W. J. Grant (very fine and sweet) ; dark Rose, H.P., A. K. Williams ; yellow Rose, Mr. Prince, Comtesse de Nadaillac (absolutely perfect in colour and symmetry).

In the herbaceous flower division there was a marked improvement in the quality of the flowers exhibited, as well as in their grouping, over former years, although a little more attention still might be of advantage, so that each variety may stand out with greater distinctness ; the general effect was good and all that could be desired.

The Judges in the nurserymen's division were the Rev. C. H. Bulmer,

FIG. 5.—CAMPANULA GRANDIFLORA MARIESI.

bloom of Her Majesty (worthy of the gracious prototype), and Tea The Bride. Third Mr. Thomas Hobbs, Easton, Bristol. In the class for eighteen varieties the first prize went to Rev. W. H. Jackson, Bedford ; second to Mr. Foley Hobbs, Worcester ; and the third to Rev. C. H. Bulmer, Credenhill, Hereford. For twelve varieties Dr. Budd was first, Mr. T. Hobbs second, and the Rev. W. H. Jackson third.

Division III. Herefordshire Amateurs.—In this section the class for eighteen varieties, first prize (with N.R.S. gold medal) was won by the Rev. Preb. G. E. Ashley, Stretton Rectory ; second, Mr. John Ough, Hereford ; third, Capt. Cotterell, Garnons, Hereford.

In the open class for eighteen Tea and Noisette, the first prize fell to Mr. G. Prince, with a superb collection, which included the following varieties :—Comtesse Nadaillac (perfect), Souvenir d'Elise Vardon, Souvenir d'un Ami, Souvenir de S. A. Prince, Princess of Wales (lovely), Catherine Mermet, Rubens, Maman Cochet (long in bud, poor habit), Madame Hoste, Madame Cusin (fine), Jean Ducher, Inocente Pirola Credenhill Rectory, Hereford ; Mr. Conway Jones, Gloucester ; and Mr. John Cranston, Townhope, Hereford. In the amateurs' division Messrs. F. and J. Cant.—HEREFORDSHIRE INCUMBENT.

SUTTON.—JUNE 29TH.

THIS was the sixteenth exhibition of the above Society, and if the entries were less numerous than we have sometimes seen here, the quality was quite up to the usual standard. Indeed, taken all round the flowers were much brighter and of better form.

In the amateurs' class, for twenty four Roses, R. E. West, Esq., Reigate, beat Mr. A. Slaughter, Steyning. Mr. West's best flowers were Etienne Levet, Maman Cochet, Annie Wood, The Bride, and Horace Vernet. For eight trebles Mr. West again defeated Mr. Slaughter, his Victor Hugo, Général Jacqueminot, François Michelon, and Ulrich Brunner being extra good. Mr. Slaughter was well ahead in a class for

twelve Teas or Noisettes; Mr. West taking second honours here. For growers of less than 2000 plants, Mr. Harris, gardener to E. M. Bethune, Esq,, Horsham, was most successful, winning for twelve singles, six trebles, and for nine Teas or Noisettes. In each class Mr. P. G. C. Burnand, Reigate, followed very closely.

Mr. M. Hodgson was equally successful in the division for growers of less than 1000 plants, defeating Mr. H P. Landon by a few points in the three chief classes; but for six Teas or Noisettes Mr. Landon excelled Mr. Hodgson. Mr. P. G. C. Burnand won with some capital La France for twelve of any variety, Mr. R. E. West following with Mrs. John Laing, and Mr. Harris with Madame Gabriel Luizet.

In the local class for twelve singles Mr. R. W. Miller was well in front, and also in a class for nine distinct. The ladies' challenge cup and silver medal of the N.R.S., offered for six distinct Roses, brought out eight competitors, Mr. W. Hooper being successful with Général Jacqueminot, Her Majesty, Marie Baumann, Dr. Andry, Mrs. George Dickson, and Ulrich Brunner. G. A. V. Schofield, Esq., and Mr. R. W. Miller followed in the order named. Mr. T. G. Delmar won with some good Mrs. John Laing for six of any Rose.

There were seven competitors in a nurserymen's class for thirty-six singles, Messrs. Harkness & Sons, Bedale, winning with a grand stand. The best twelve were Comtesse de Ludre, Sir R. Hill, E. Y. Teas, Mrs. W. J. Grant, S. Marie Rodocanachi, F. Michelon, Mrs. Crawford, La France, Marie Verdier, E. Levet, Victor Hugo, and Helen Keller. Mr. B. R. Cant, Colchester was a close second; and Messrs. Prior & Son, Colchester, third. This was a very closely contested class, and all were really good. For twelve Teas or Noisettes Mr. G. Prince, Oxford, won with C. de Nadaillac, Souvenir de S. A. Prince, Maman Cochet, Jean Ducher, Princess of Wales, Souvenir d'un Ami, Madame Hoste, Souvenir d'Elise Vardon, Niphetos, Maréchal Niel, The Bride, and Medea. Messrs. Prior & Son and Mr. B. R. Cant followed.

Table decorations, baskets, bouquets, sprays, and other floral designs were tasty, and well exemplified what can be done in this direction with Roses only.

EALING.—June 30th.

For over thirty years the Ealing Horticultural Society has held annual exhibitions in the populous and salubrious district which could once be more accurately described than now as a far western suburb of London. Of late years, however, the huge metropolis has advanced as with giant strides in all directions, and not least westerly, and as Ealing has grown, too, to a remarkable extent, it is a far western suburb no longer, but practically joins hands with the greatest city in the world. Still there are "open spaces," more or less extensive, of common land, market garden fields, and here and there a park attached to what was once a country residence; and thus it is that vegetation flourishes in various forms, and even Roses, for which the district has long been famed, still display their charms, and Roses were, in fact, the most prominent feature of the show this year.

The site was an ideal one—namely, the grounds of Gnnnersbury Park, kindly placed at the disposal of the Committee by Lord Rothschild and his garden-loving brother Leopold de Rothschild, Esq., and as the pleasure grounds and flower gardens were generously open to visitors a treat of no ordinary character was afforded. The exhibition was essentially local, and as anything like a list of prizewinners could only possess local interest no attempt whatever will be made to deal with the several classes. There was, however, at least one open class and special prizes for Roses that must not be overlooked.

The principal class was for forty-eight blooms, not more than two of any one variety. The honours had to be divided between three exhibitors—namely, Mr. Charles Turner, Slough; Messrs. G. & W. H. Burch, Peterborough; and Mr. George Cannon, St. John's Nursery, Ealing, and they were accorded in the order named. At the first glance the Peterborough stands appeared the heavier, hut a close scrutiny made clear the fact that they were more developed, some of them rather too much so, and had lost freshness, whereas the Slough Roses were beautifully clear and bright; grand blooms, too, many of them were, especially Madame G. Luizet, Marchioness of Londonderry, Souvenir de President Carnot, Margaret Dickson, Her Majesty, and Beauté Lyonnaise, the last named being particularly charming. Others in the stands were Reynolds Hole, Cheshunt Hybrid, Maurice Bernardin, Dnchesse de Morny, A. K. Williams, Horace Vernet, Mrs. R. G. S. Crawford, Mrs. Harkness, Victor Hugo, Mrs. J. Laing, Louis Van Houtte, S. M. Rodocanachi, Marie Baumann, Charles Lefebvre, Duc de Wellington, François Michelon, Fisher Holmes, Xavier Olibo, Lady Sheffield, Charles Darwin, La France, Helen Keller, Dupuy Jamain, Salamander, Sultan of Zanzibar, Sir Rowland Hill, Prince Camille de Rohan, and Duchess of Fife. The second and third prize stands contained excellent representatives of popular varieties, and the whole made a meritorious display.

In another class for twenty-four Roses there were twelve competitors, the first prize being a Jubilee cup, the second the gold medal of the National Rose Society, the third a silver-gilt, and the fourth a silver medal—excellent provision it will be conceded in one class. The merits of some of the competing stands were very close, but eventually the awards were apportioned as follows:—The Jubilee cup to E. P. Oakshott, Esq., Orchardine (gardener, Mr. C. Long); the gold medal to W. Owen, Esq., The Elms, Castle Bar (gardener, Mr. R. Green); the silver-gilt medal to W. Ponting, Esq., Monnt Avenue (gardener, Mr. H. Shingle); and the silver medal to R. Dawes, Esq.. Edmoncote House (gardener, Mr. S. Wickenden), all staging very well indeed. There were several other classes, including one in which an exhibitor lost the first prize for Teas and Noisettes through including a bloom of La France, no doubt in a moment of forgetfulness of the N.C.S. rules, by which the judging had to be done.

In several of the minor classes for Roses the arrangement of the blooms was very faulty, most of them appearing as if crushed down as low as they could be; but not so a magnificent collection of Messrs. James Veitch & Sons, which afforded an excellent object lesson in growing and staging, the best varieties being splendidly represented, and certainly the most meritorious exhibit in the show. The only other exhibits in the cut flower section worthy of praise were stands of Gloxinias, twelve varieties in triplets, with Fern. They were fresh and beautiful, well deserving the award. Bunches of hardy herbaceous plants were too much huddled, spoiling the effect, but some of the table decorations were very attractive.

Many groups of plants were arranged, some on the ground, others, and smaller, on tables; and though there were pleasing associations of plants in some groups, there was too much packing in others, while in one bright little group on the table the exhibitor had neither masked the pots nor washed them. It was a pleasure to turn from the semicircle of dirty pots to the two really fine non-competitive groups of Mr. G. Reynolds, Gunnersbury Park, in which Palms, Crotons, Celosias, Carnations, Gloxinias, and other plants were effectively displayed; and of Mr. J. Hudson, Gunnersbury House, who had among the taller plants a pyramid Nectarine tree aglow with fruit, and in the front a collection of Marliac's charming Water Lilies, the equal of which could probably not have been obtained from any other garden in the kingdom. As a pendant of the show a number of florally decorated bicycles attracted a crowd of people, and would increase the "takings" considerably.

The Gunnershnry Pleasure Grounds were beautiful and enjoyable, magnificent Cedars standing in far-spreading cushions of Ivy, and from it springing in informal groups stately Foxgloves, with the lake in front sparkling with Water Lilies, presented a combination of charms rarely to be seen. Then there are large Rose beds and beds of other flowers arched with Roses, the whole forming a garden of sweetness and beauty of the most delightful kind.

On the "other side" (Mr. Hudson's department was not open to the public; it is too full of glass to find room for the multitude)—the walks are lined with fruit trees in pots, the finest private collection we have seen. Houses filled with fruit trees—Figs, Vines, and Melons—to meet the great demand, which they appear well able to do. Pleasure grounds full, also a beautiful and interesting private nook, with its small lake, with twenty-eight varieties of Marliac's Lilies, and not a small, but large bush of Bambusa Metake, planted out of a 6-inch pot some years ago by Mr. Hudson, and now 20 feet in diameter. Then there is something to see underground in an ancient cellar—namely, beds literally "white over" with Mushrooms, and this abundance is maintained all the year round. A veritable *multum in parvo* is this garden, and a stroll through it, also through the greater one, open to the public, added to the pleasure of a visit to this well managed, attractive, and diversified Ealing Show.

CROYDON.—June 30th.

This was again a grand show—plants, groups, and especially the Roses being better than usual. Numbers and quality were good throughout the show.

In the nurserymen's class for forty-eight varieties, Messrs. Harkness and Sons, Bedale and Hitchin, were placed first; the stand contained some really good and highly coloured blooms. Mr. B. R. Cant, Colchester, was a close second; and Messrs. D. Prior & Sons, of Colchester, third. The same three exhibitors scored in a class for twenty-four varieties, three of each, the order being Mr. B. R. Cant, Messrs. Prior and Sons, and Messrs. Harkness & Sons. In both classes the competition was very close indeed. Messrs. G. & W. H. Burch, Peterborough, won for twenty-four singles; Mr. G. W. Piper, Uckfield, following closely. The prizewinners in the class for Teas and Noisettes all came from Colchester; Messrs. D. Prior & Sons, Messrs. F. Cant & Co., and Mr. B. R. Cant winning in the order named. Messrs. F. Cant & Co. were first for twelve of any H.P. or H.T. with good Kaiserin Augusta Victoria, and Mr. B. R. Cant with twelve Madame Cusin in the class for Teas or Noisettes.

There were also five competitors for the new challenge cup offered to amateurs for thirty-six distinct varieties. Mr. E. B. Lindsell, Hitchin, easily won with some superb flowers. Among these were the two silver medal blooms, Her Majesty securing one for the best H.P., and Mrs. John Laing the other as the flower of that variety. Mr. T. B. Haywood, Reigate, was second in the cup class. Mr. Mease, gardener to A. Tate, Esq., Leatherhead, won for a good stand of twenty-four, distinct; and Mr. Harris, gardener to E. M. Bethune, Esq., Denne Park, Horsham, for eighteen Teas or Noisettes. For growers of less than 2000 plants, Mr. E. Mawley, Berkhamsted, secured the premier honour for twelve distinct, and also for twelve Teas or Noisettes; E. M. Bethune, Esq, being a close second in each class.

Mr. J. W. Cook, The Briers, North Finchley; W. D. Freshfield, Esq., The Wilderness, Reigate; and Mr. M. Hodgson, Shirley, were very successful among amateurs. The challenge cup and N.R.S. silver medal for local growers were secured by Mr. A. C. Gifford, South Norwood.

Plants and groups were very good. Mr. Mills, gardener to F. G. Lloyd, Esq., Coombe House, Croydon, won for twelve table plants, for six Dracænas, for six Caladiums, for some grand specimens of Selaginellas, and for twenty-four hardy cut flowers; Mr. C. J. Salter,

gardener to T. B. Haywood, Esq., Reigate, winning for twenty-four stove and greenhouse cut flowers. One of the most successful exhibitors in this division was Mr. Harris, gardener to P. Crowley, Esq., Waddon House, Croydon, who was well ahead for groups, for nine ornamental foliage plants, for six stove and greenhouse plants in bloom, for six exotic Ferns, and for both specimen foliage and flowering plants.

Special mention must be made of Messrs. J. Laing & Sons' grand groups of Begonias, also of Caladiums and herbaceous cut flowers. Messrs. Wallace & Co., Colchester, had a superb stand of Calochortuses.

CRYSTAL PALACE.—JULY 2ND.

ON Friday last the National Rose Society held its metropolitan meeting in the Crystal Palace, and it is with pleasure that we are able to state that the exhibition was distinctly an advance on that of last year. Not only was there improvement in the number of exhibits, but the quality was decidedly superior. Last year there were 528 entries, while this year the total was 669, or an increase of 141. It is not, of course, probable that all the entries were staged, but there were sufficient to give an exceedingly beautiful spectacle. In all sections the Roses staged were good as a whole, the Hybrid Perpetuals being stout in petal and good in colour, while the Teas and Noisettes were, if not large, at any rate of singular beauty, many of the specimens being absolutely perfect. The thundery weather that we have experienced of late had left its mark upon some of the blooms, but they were not so much damaged as some might have been led to suppose.

As was the case last year, there were fifty-eight classes in the schedule, comprising those for Hybrid Perpetuals, Teas and Noisettes, Hybrid Teas, garden Roses, vase of Roses, and table decorations. In every instance there was competition, in some perhaps only two or three rivals, whereas in others the stands numbered between a dozen and eighteen. Occasionally it was extremely easy to find the first prize-winners; more frequently, however, the work of the Judges was difficult, but as there were two or three score of them they cannot be said to have had too much to do. Taken as a whole this was probably the finest the Society has held.

Now a word or two as to the arrangements, which we presume were carried out by the officials of the Palace. We do not wish to find fault unnecessarily, but in this case it is our duty to call attention to the utter lack of method in placing the exhibits. It seemed as though an effort had been made to divide the classes as much as possible, and not only that, but the several boxes in one class were frequently on tables some distance apart. This, of course, caused the Judges much needless hurrying about, and in one instance at least they had to do their work over again, having missed out some stands that were away from the others, and one of which eventually took the first prize. Then, again, the position occupied by the majority of the amateurs' exhibits was one of the worst that could be found, as it was so dark that it was extremely difficult to read the names, and impossible to see the colours of the flowers. We hope that at subsequent shows a strong effort will be made to place the classes consecutively, as was done at Halifax a year or two back, as well as providing a place where the flowers can be properly seen by the hundreds of interested visitors.

NURSERYMEN'S CLASSES.

The class for seventy-two distinct single trusses, with the first prize in which goes the champion trophy, is the one that always attracts the most attention from rosarians. All alike are anxious to know who has won, and this time the excitement was as keen as ever. As was the case in 1896, Messrs. Harkness & Son, Bedale, were adjudged the champions, followed by Mr. B. R. Cant and Messrs. F. Cant & Co., there being two unsuccessful exhibitors. The winning exhibit was composed of good flowers, beautifully staged. The varieties were Comte de Raimbaud, Madame Gabriel Luizet, Sir Rowland Hill, Madame Joseph Bonnaire, Prince Arthur, The Bride, Marie Baumann, Kaiserin Augusta Victoria, Crown Prince, Madame Eugène Verdier, Comtesse de Ludre, Viscountess Folkestone, Earl of Dufferin, Mrs. W. J. Grant, Victor Hugo, Caroline Testout, Marie Rady, Madame Delville, Exposition de Brie, Star of Waltham, Duke of Teck, Marie Verdier, Marchioness of Dufferin, Duke of Edinburgh, Marchioness of Londonderry, Camille Bernardin, Madame de Watteville, Susanne Marie Rodocanachi, Catherine Mermet, Jean Liabaud, Margaret Dickson, Général Jacqueminot, Marquise de Castellane, Xavier Olibo, Helen Keller, Thomas Mills, White Lady, Abel Carrière, Lady Mary Fitzwilliam, A. K. Williams, François Michelon, Charles Lefebvre, Beauty of Waltham, Dupuy Jamain, Marchioness of Downshire, Duke of Wellington, Marquis de Litta, Duc d'Orleans, Madame Cusin, Gustave Piganeau, Madame Montet, Duke of Connaught, Mrs. J. Laing, Edouard André, Silver Queen, Horace Vernet (perfect), Souvenir d'Elise Vardon, Fisher Holmes, Mrs. R. G. Sharman Crawford, Captain Hayward, Etienne Levet, Maréchal Niel, Madame Haussman, Mrs. Paul, Mrs. Jowett, Duchesse de Morny, La France, Dr. Andry, and Ulrich Brunner. Amongst so many it must be expected that there will be a few weak flowers, but these in this stand were very few.

As has been said, the second position was accorded to Mr. B. R. Cant, Colchester, who staged many handsome Roses. We cannot afford the space to mention all, but a few good ones were Princess of Wales, Souvenir de S. A. Prince, Madame Hoste, Duchesse de Morny, Marguerite Boudet, Marie Verdier, Susanne Marie Rodocanachi, Duke of Wellington, Mrs. W. J. Grant, Madame Cusin, Maman Cochet, Bridesmaid, Madame de Watteville, Dr. Andry, Annie Laxton, Jean Soupert, and Caroline Testout. The third prize was well won by Messrs. Frank Cant & Co., Colchester, who also showed very strongly in some instances.

In the class for forty distinct varieties, three blooms of each, Mr. B. R. Cant was a splendid first with an even exhibit of fresh, well-coloured flowers of the following varieties:—Her Majesty, Horace Vernet, Mrs. R. G. Sharman Crawford, Gustave Piganeau, White Lady, Susanne Marie Rodocanachi, Caroline Testout, Alfred Colomb, Helen Keller, Marie Baumann, Marchioness of Dufferin, Dupuy Jamain, La France, Earl of Dufferin, Lady Mary Fitzwilliam, Ulrich Brunner, Marchioness of Londonderry, Beauty of Waltham, Mrs. John Laing, A. K. Williams, Jean Soupert, Merveille de Lyon, François Michelon, Madame de Watteville, Victor Hugo, Souvenir de S. A. Prince, Camille Bernardin, Madame Gabriel Luizet, Duke of Teck, Margaret Dickson, Duchesse de Morny, Madame Cusin, Etienne Levet, Catherine Mermet, Le Havre, Kaiserin Augusta Victoria, Fisher Holmes, Madame Eugène Verdier, Marquis de Litta, and Maman Cochet. Messrs. Harkness & Sons were placed second. Their stand was also highly creditable, and as usual the arranging was done with much skill and care. Noticeable in this exhibit were Mrs. John Laing, Helen Keller (splendid), Prince Arthur, Camille Bernardin, Horace Vernet, Madame Cusin, and Mrs. W. J. Grant. Messrs. Frank Cant & Co. were accorded the third position. The competition in this class was strong.

Several competitors came forward in the class for forty-eight distinct single trusses, and the Judges were a considerable time before they gave the prizes to Messrs. J. Townsend & Sons, Worcester; Messrs. J. Burrell & Co., Howe House Nurseries, Cambridge; and Messrs. G. and W. H. Burch in the order in which their names are here given. We believe this is the first occasion on which Messrs. Townsend have set up a forty-eight, and they are to be congratulated on their success. The blooms comprised Gustave Piganeau, Lady Mary Fitzwilliam, Heinrich Schultheis, Pride of Waltham, Charles Lefebvre, Mrs. R. G. Sharman Crawford, Alfred Colomb, White Lady, Marquis de Litta, Caroline Testout, Camille Bernardin, Madame Eugène Verdier, Victor Verdier, La France, Dupuy Jamain, Mrs. John Laing, Catherine Mermet, Susanne Marie Rodocanachi, Marie Van Houtte, Xavier Olibo, François Michelon, A. K. Williams Her Majesty, Duchesse de Morny, Madame Gabriel Luizet, Fisher Holmes, Marchioness of Londonderry, Comte de Raimbaud, Innocente Pirola, Marie Verdier, Kaiserin Augusta Victoria, Victor Hugo, Prince Arthur, The Bride, Horace Vernet, Souvenir de S. A. Prince, Margaret Dickson, Lord Bacon, Catherine Kuster, Marie Baumann, Jean Ducher, Madame Cusin, Comtesse de Panisse, Duke of Edinburgh, Anna Olivier, Beauty of Waltham, and Medea. Messrs. J Burrell & Co., who were second, staged The Bride, Duke of Connaught, Innocente Pirola, Horace Vernet, Captain Hayward, Général Jacqueminot, and Xavier Olibo, amongst others, in good form. Messrs. G. and W. H. Burch, Peterborough, were third.

There were ten entries in the class for twenty-four distinct single trusses, and some blooms of great beauty were staged by many of the exhibitors. Mr. Charles Turner, Royal Nurseries, Slough, was first with Victor Hugo, Marchioness of Londonderry, Xavier Olibo, Mrs. John Laing, Duchesse de Morny, Prince Arthur, Her Majesty, Caroline Testout, Mons. E. Y. Teas, Ulrich Brunner, Louis Van Houtte, Pride of Waltham, Penelope, François Michelon, Marie Baumann, Madame Victor Verdier, Lady Sheffield, Fisher Holmes, Ernest Metz, Dr. Andry, Madame Gabriel Luizet, A. K. Williams, and Gustave Piganeau. Mr. J. Mattock, New Headington, Oxford, was second, his best blooms being Duchesse de Morny, Mrs. John Laing, Innocente Pirola, Duchess of Bedford, and Earl of Dufferin. Mr. R. Crossling, Nurseries, Penarth, South Wales, was a poor third.

Messrs. D. Prior & Sons, Colchester, were a splendid first in the class for twenty-four distinct, three blooms of each, the stand being composed of many beautiful examples. The varieties were Caroline Testout, Ulrich Brunner, Marchioness of Dufferin, Alfred Colomb, Gustave Piganeau, Mrs. John Laing, Camille Bernardin, Her Majesty, A. K. Williams, La France, La Rosière, Marchioness of Downshire, François Michelon, Pride of Waltham, Etienne Levet, Mrs. R. G. Sharman Crawford, Susanne Marie Rodocanachi, Madame Eugène Verdier, Abel Carrière, Kaiserin Augusta Victoria, Marie Finger, Marquis de Litta, Marchioness of Londonderry, and Horace Vernet. Mr. G. Mount, Canterbury, was placed second, Général Jacqueminot, Ulrich Brunner, Margaret Dickson, Mrs. R. G. Sharman Crawford, Caroline Testout, and Madame Gabriel Luizet being conspicuous in this exhibit. Messrs. J. Townsend & Sons were third.

An extra class, open to all nurserymen, with the first prize in which went the Dickson cup, brought five competitors. It was for twelve distinct single trusses, Messrs. Harkness and Sons taking the coveted award. Their blooms were Helen Keller, Earl of Dufferin, Marchioness of Londonderry, Mrs. W. J. Grant, Marchioness of Dufferin, Mrs. R. G. Sharman Crawford, Muriel Grahame, Marchioness of Downshire, Margaret Dickson, Jeannie Dickson, Ethel Brownlow, and one other. Mr. B. R. Cant was second, and Messrs. F. Cant & Co. third. The blooms had to be from varieties that have been sent out by Messrs. A. Dickson & Sons, Newtownards.

TEAS AND NOISETTES.—In the nurserymen's classes in this section of the show many flowers of the greatest beauty were staged, some varieties especially being particularly rich in colour, and of perfect form and substance. The chief class was for twenty-four single trusses, distinct, the premier position being taken by Messrs. F Cant & Co. with some lovely examples. The varieties included Madame Cusin, Madame Hoste, Madame de Watteville, Souvenir de S. A. Prince, Maman Cochet, Hon. Edith Gifford, Souvenir d'un Ami, The Bride, Souvenir d'Elise Vardon, Comtesse de Nadaillac, May Rivers, Catherine Mermet, Amazone, Jean Ducher, Madame Bravy, Marie Van Houtte, Etoile de Lyon, Ernest Metz, Francisca Kruger, Ethel Brownlow, Medea, Anna

Ollivier, and Comtesse de Panisse. The second position was taken by Messrs. D. Prior & Son, whose examples of Maman Cochet, Cleopatra. Luciole, Madame Lambard, and Madame Cusin were very fine. Mr. G. Prince, Oxford, with smaller flowers, was third.

Messrs. J. Burrell & Co. were to the front for eighteen Teas and Noisettes, distinct, one truss of each, with Madame de Watteville, Madame Hoste, Ernest Metz, The Bride, Souvenir d'un Ami. Jean Ducher, Princess of Wales, Niphetos, Golden Gate, Maman Cochet, Madame Cusin, Catherine Mermet, Bridesmaid, Etoile de Lyon, Ethel Brownlow, Madame Angele Jacquier, Maréchal Niel, and Muriel Grahame. The second place was filled by Mr. J. Mattock, whose blooms were rather larger than those in the previous stand, but decidedly less refined. Amongst the best were Ernest Metz, Ethel Brownlow, Madame Cusin, Alba Rosea, and the Hon. Edith Gifford. Messrs. J. Townsend & Sons were third.

For eighteen trebles, distinct, of Teas and Noisettes Mr. George Prince was first, his blooms being very fine. They comprised The Bride, Maman Cochet, Alba Rosea, Madame Cusin, Princess of Wales, Souvenir de S. A. Prince, Souvenir d'un Ami, Innocente Pirola, Comtesse de Nadaillac, Niphetos, Catherine Mermet, Anna Ollivier, Ernest Metz, Ethel Brownlow, Mons. Furtado, Madame de Watteville, Jean Ducher, and Marie Van Houtte. Mr. B. R Cant was second, his stand containing Luciole, Madame Cusin, Marie Van Houtte, Comtesse de Nadaillac, The Bride, and Madame de Watteville. Messrs. D. Prior & Sons were third, all the stands being good.

Amateurs' Classes.

As is customary at this show, the number of classes devoted to amateurs was very large, and many of the stands comprised some perfect blooms. In a few of the classes the competition was not particularly keen, but as a rule the entries were numerous, and the pointing close. A few well known growers were conspicuous by their absence, but some new ones had come in to occupy the vacancies. Such rosarians as E. B. Lindsell, Esq., C. J. Grahame, Esq., the Rev. J. H. Pemberton, the Rev. A. Foster Melliar, Alfred Tate, Esq., O. G. Orpen, Esq., and A. Slaughter, Esq., staged strongly and well maintained their reputation.

The amateurs' champion trophy class was the one to attract the greatest amount of attention from the rosarian visitors. The excitement relative to it is always very intense, and this year proved no exception. The Rev. J. H. Pemberton succeeded in getting top place last year, while in Friday's show E. B. Lindsell, Esq., Hitchin, was the winner with a beautiful exhibit, containing several flowers of the first quality. The number of blooms required was thirty-six in distinct varieties, the winning stand containing Ulrich Brunner, Marchioness of Londonderry, Charles Lefebvre, Marchioness of Dufferin, Gustave Piganeau, Her Majesty, Alfred Colomb, Susanne Marie Rodocanachi, Mrs. W. J. Grant, Duc d'Orleans, Mrs. John Laing, Duchess of Bedford, François Michelon, Dr. Andry, Innocente Pirola, Horace Vernet, Comtesse de Nadaillac, Muriel Grahame (superb), Madame Victor Verdier, Madame Hoste, Prince Arthur, Madame de Watteville, Dr. Sewell, La France, Fisher Holmes, Catherine Mermet, Madame Haussman, Madame Gabriel Luizet, Earl of Dufferin, Madame Cusin, A. K. Williams, Kaiserin Augusta Victoria, Sir Rowland Hill, Louis Van Houtte, and Merveille de Lyon. The second position was taken by Chas. J. Grahame, Esq., Leatherhead; and the third by H. V. Machin, Esq., Gateford Hill, Worksop.

Another class for thirty-six distinct single trusses was also won by E. B. Lindsell, Esq., the exhibit again being a handsome one. The blooms were Mrs. John Laing, Susanne Marie Rodocanachi, Edward Andre, Comtesse d'Oxford, Madame Hoste, Duc d'Orleans, Kaiserin Augusta Victoria, Comte de Raimbaud, Heinrich Schultheis, Earl of Dufferin, Madame de Watteville, Duchess of Caylus, Caroline Testout, Louis Van Houtte, Charles Lefebvre, Captain Hayward, Madame Gabriel Luizet, Alfred Colomb, La France, Horace Vernet, Her Majesty, Gustave Piganeau, Innocente Pirola, Marie Baumann, Marchioness of Dufferin, Prince Arthur, Muriel Grahame, François Michelon, Catherine Mermet, Dr. Andry, Souvenir d'Elise Vardon, Le Havre, A. K. Williams, Ulrich Brunner, Merveille de Lyon, and Mons. E. Y. Teas. E. Hobbs, Esq., Easton, Bath; and Mr. W. Mease, gardener to Alfred Tate, Esq., Downside, Leatherhead, took the second and third prizes in the order in which their names are given.

In the class for eight distinct varieties, three blooms of each, the successful competitors were E. B. Lindsell, Esq.; the Rev. J. H. Pemberton, and Mr. W. Mease, in the order of their names. The winner staged fine specimens of Mrs. W. J. Grant, Earl of Dufferin, Ulrich Brunner, Marchioness of Londonderry, Mrs. John Laing, Horace Vernet, Her Majesty, and A. K. Williams.

For twelve single trusses of any Rose except Teas and Noisettes the first prize went to H. V. Machin, Esq., with superb examples of Gustave Piganeau. Mr. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford, was second; and the Rev. J. H. Pemberton third.

Open only to growers of less than 2000 plants.—In this section the class for twenty-four distinct single trusses, S. S. Berger, Esq., Bragbury, Stevenage, was placed first, though the stand exhibited by Edward Mawley, Esq., Rosebank, Berkhampsted, which took second prize, was apparently the better one of the two. R. E. West, Esq., Reigate, was third.

For six trebles, distinct, E. Mawley, Esq., went to the front with beautiful specimens of Mrs. John Laing, Horace Vernet, Madame Gabriel Luizet, Ulrich Brunner, Dupuy Jamain, and Marie Finger. Percy Burnand, Esq., Reigate, was second, and Conway Jones, Esq., Hucclecote, Gloucester, third.

O. G. Orpen, Esq., with splendid blooms of Kaiserin Augusta Victoria was first in the class for nine blooms of any Rose other than a Tea or Noisette; E. M. Bethune, Esq., Horsham, was second with Marie Baumann, and A. Slaughter, Esq., Steyning, third, with Charles Lefebvre.

Open only to growers of less than 1000 plants.—There were only two classes in this section, but the competition was keen, the entries numerous, and the quality good. For nine distinct single trusses George Moules, Esq., Hitchin, was an excellent first, with a splendid stand comprising Caroline Testout, Earl of Dufferin, François Michelon, Her Majesty, Catherine Mermet, Ulrich Brunner, Souvenir d'Elise Vardon, Comte de Raimbaud, and Beauty of Waltham. M. Whittle, Esq., Leicester, was second, and Mrs. A. F. Perkins, Holmwood, Surrey, third.

The other class was for six distinct trebles, the first prizewinner being G. W. Cook, Esq., Finchley. His blooms were La France, Captain Hayward, Mrs. John Laing, Ulrich Brnnner, Kaiserin Augusta Victoria, and Général Jacqneminot. R. H. Langton, Esq., Hendon, with small flowers, was second, and M. Whittle, Esq., third.

Open only to growers of less than 500 plants.—Those growers whose stock of plants does not exceed the above number were given three classes in which to show their mettle. For nine distinct single trusses R. F. Hobbs. Esq., Bromyard Road, Worcester, followed by R. W. Bowyer, Esq., Hertford, and F. J. Fletcher, Esq., Bray, in the order named. For six distinct single trusses, the first, second, and third prizewinners were Messrs. A. Mount, Slough; E. R. Smith, Muswell Hill; and G. A. Hammond, Burgess Hill, respectively; H. P. Landon, Esq., Brentwood, taking the fourth place. The last named gentleman secured the leading award for four trebles, distinct, with Caroline Testout, Mrs. John Laing, Victor Hugo, and La France. J. Parker, Esq., Old Headington, was second; and R. Foley Hobbs, Esq., third.

Extra classes.—In addition to the several specified classes already noted there were several others with some restrictions, and to these we shall now refer under the above heading. In a class only to those eligible to compete in classes 14 to 18, for twelve distinct single trusses, C. J. Grahame, Esq., offered a handsome silver cup to the chief prizewinner. This was won by W. Kingston, Esq, Grey Street, Bedford, who showed Ulrich Brunner, Souvenir d'Elise Vardon, Alfred Colomb, Xavier Olibo, Catherine Mermet, Louis Van Houtte, Mrs. John Laing, Camille Bernardin, A. K. Williams, La France, Général Jacqueminot, and Etienne Levet, in highly creditable form. The Rev. A. Cecil Johnson, Capel St. Mary, was second, and M. Whittle, Esq., third. For six blooms of any Hybrid Perpetual or Hybrid Tea, G. W. Cook, Esq., was first with Mrs. John Laing; J. O. Trueman, Esq., Swanley, second with Her Majesty, and R. W. Bowyer, Esq., third with Caroline Testout. This class was subject to the same restrictions as the one immediately preceding it.

In a class for six distinct single trusses, open to all amateurs, C. J. Grahame, Esq., offers a cup known as the Dickson cup for blooms of varieties sent out by Messrs. A. Dickson & Sons, Newtownards, Ireland. E B. Lindsell, Esq., secured the coveted honour with examples of Helen Keller, Marchioness of Londonderry, Marchioness of Dufferin, Earl of Dufferin, Muriel Grahame, and Mrs. R. G. Sharman Crawford in good form. The Rev. J. H. Pemberton was second, and A. Slaughter, Esq., third.

The Rev. A. Cecil Johnson was the most successful competitor in the class for six distinct single trusses. No competitor was allowed to exhibit who had previously won a prize at any show of the National Rose Society. Mr. Johnson staged Kaiserin Augusta Victoria, Ulrich Brunner, François Michelon, Marie Baumann, and Mrs. John Laing. J. C. Trueman, Esq., was second, and F. Brewer, Esq., Wood Green, third. In this class the first prize took the form of a piece of plate presented by Messrs. D. Prior & Sons, Colchester. For six blooms, distinct, from growers who had joined the Society since the Crystal Palace Show last year, S. S. Berger, Esq, was first; Miss Jebb, Rotherham, second, and the Rev. R. Powley, Warminster, third.

E. Mawley, Esq., offered as the first prize in a class for six distinct single trusses a piece of plate of the value of 2 guineas. The restriction was that the flowers should have been grown within eight miles of Charing Cross. The winner, G. W. Cook. Esq., staged La France, Captain Hayward, Comtesse d'Oxford, Caroline Testout, Duke of Wellington, and Mrs. John Laing. J. Bateman, Esq., Highgate, was second; and E. R. Smith, Esq., third.

Then there was a class for six distinct single trusses of new Roses, open to all amateurs. The Rev. J. H. Pemberton was first with Marquis de Litta, Marchioness of Downshire, Captain Hayward, Helen Keller, Mrs. R. G. Sharman Crawford, and Charlotte Guillemot. O. G. Orpen, Esq., was second; and J. Bateman, Esq., third.

Teas and Noisettes. — Corresponding in importance with the amateurs' trophy for thirty-six distinct Roses is what is designated the Tea and Noisette trophy, the class being open to all amateurs, irrespective of the number of plants which they grow. Eighteen distinct single trusses were required, and as usual the class caused a considerable amount of interest. O. G. Orpen, Esq., was the winner with a stand composed of some lovely specimens, including Maman Cochet, Madame Hoste, Souvenir d'Elise Vardon, Souvenir d'un Ami, The Bride, Ernest Metz, Innocente Pirola, Comtesse de Nadaillac, Princess of Wales, Madame Cusin, Cleopatra, Marie Van Houtte, Catherine Mermet, Medea, Maréchal Niel, Sylph, Caroline Kuster, and Madame de Watteville. C. J. Grahame, Esq., was second with a charming exhibit; and S. P. Budd, Esq., Gay Street, Bath, third.

In the class for twelve Teas and Noisettes, open to all amateurs, E. M. Bethune, Esq., was first with an even stand. The varieties were

Maman Cochet, Francisca Kruger, Madame Cusin, Medea, Catherine Mermet, Caroline Kuster, The Bride, Bridesmaid, Madame Margottin, Marie Van Houtte, Etoile de Lyon, and Ethel Brownlow. The Rev. Hugh Berners, Harkstead Rectory, Ipswich, was a good second, and S. P. Budd, Esq., third.

C. J. Grahame, Esq., was first in the open amateurs' class for eight distinct single trusses, staging Madame de Watteville, Caroline Kuster, Maman Cochet, Innocente Pirola, Catherine Mermet, Francisca Kruger, Madame Cusin, and The Bride. S. P. Budd, Esq., was a fair second, and O. G. Orpen third. For nine single trusses of any Tea or Noisette E. M. Bethune, Esq., was first with Catherine Mermet in fine form, C. J. Grahame, Esq., second with beautiful Madame Cusin, and O. G. Orpen third with the same variety.

Open only to growers of less than 500 *Teas or Noisettes.*—J. Parker, Esq., was first in the class for twelve distinct single trusses of Teas and Noisettes with Madame Cusin, Marie Van Houtte, Princess of Wales, Catherine Mermet, Madame Hoste, Madame de Watteville, Caroline Kuster, and Anna Ollivier. The second and third positions were taken by the Rev. J. H. Pemberton and Conway Jones, Esq.

For nine distinct single trusses of Teas or Noisettes, Miss Baker, Reigate, was first with Maman Cochet, Madame Hoste, Ernest Metz, Alba Rosea, Etoile de Lyon, Jean Ducher, Princess of Wales, The Bride, and Francisca Kruger. P. Burnand, Esq., second; and E. Mawley, Esq., third.

Open only to growers of less than 200 *Teas and Noisettes.*—The Rev. A. Cecil Johnson was first in the class for nine distinct Teas or Noisettes. The varieties were Medea, Corinna, Cleopatra, Madame de Watteville, Madame Cusin, Souvenir d'Elise Vardon, Princess of Wales, Madame Lambard, and The Bride. G. Moules, Esq., was a good second; and J. Parker, Esq., third.

The Rev. F. Burnside, Berrington Rectory, Shrewsbury, was first for six Teas or Noisettes, distinct, one truss of each. His flowers represented Madame Bravy, Comtesse de Nadaillac, Innocente Pirola, Jean Ducher, Hon. Edith Gifford, and Catherine Mermet. M. Whittle, Esq., was second; and R. W. Bowyer third.

Extra Tea and Noisette classes.—The following two classes were open only to those entitled to exhibit in classes 33 to 36 inclusive. In the one for four trebles, distinct, J. Parker, Esq., was first. The varieties staged were The Bride, Madame Cusin, Catherine Mermet, and Marie Van Houtte. A. Slaughter, Esq., was second, and Conway Jones, Esq., third. For six single trusses of any one variety R. Foley Hobbs, Esq., was first with Catherine Mermet in good form, J. Parker second with the same variety, and Mrs. E. Croft Murray, Ryde, third with the Hon. Edith Gifford.

Messrs. Paul & Son, Cheshunt, offer a piece of plate as the first prize in an open class for six bunches of Teas or Noisettes, seven trusses of a variety to comprise a bunch. O. G. Orpen, Esq., was first with Anna Ollivier, Medea, Marie Van Houtte, Madame Hoste, Madame Cusin, and Francisca Kruger. J. Gurney Fowler, Esq., was second, and J. Parker third.

Open Classes.

Having given an idea as to the chief prizewinners in the nurserymen's and amateurs' sections, we will now see what was staged in the section headed "Open Classes," which comprised the following eleven classes. Here again the excellent flowers staged were very numerous, and the weak ones few. The whole of the exhibitors were nurserymen, and some of the stands were of exceptional beauty.

Mr. J. Mattock was a splendid first in the class for twelve bunches, not more than seven trusses to a bunch, to consist of any varieties of H.P., H.T., T., or N. Space occupied by exhibit not to exceed 6 feet by 4 feet. Amongst the varieties were Margaret Dickson, Innocente Pirola, Comtesse de Nadaillac, Madame Hoste, Madame de Watteville, and Marie Van Houtte. Messrs. Paul & Son were second, and R. Crossling third.

For twelve single trusses of Hybrid Teas, in not less than nine varieties, Messrs. D. Prior & Sons were first with La France, Kaiserin Augusta Victoria, Caroline Testout, Marquis de Litta, White Lady, Mrs. W. J. Grant, Captain Christy, Augustine Gainoisseau, La Fraicheur, and Lady Mary Fitzwilliam in good condition. Messrs. A. Dickson & Sons were second, and Messrs. Frank Cant & Co. third.

Mr. G. Prince, Oxford, was first in the class for twelve single trusses of any yellow Rose with superb examples of Comtesse de Nadaillac. Messrs. J. Townsend & Son were second with beautifully coloured Marie Van Houtte, and Mr. B. R. Cant third with Madame Hoste.

In the class for twelve single trusses of any white Rose the competition was very keen, and many superb Roses were staged. Messrs. A. Dickson & Son were placed first with chaste examples of Kaiserin Augusta Victoria; Mr. B. R. Cant came second with Marchioness of Londonderry, and Messrs. J. Townsend & Son third.

A. K. Williams, staged by Messrs. A. Dickson & Son, was to the front in the class for twelve trusses of any crimson Rose, and excellent the flowers were. Messrs. D. Prior & Son came second with Ulrich Brunner, and Messrs. J. Townsend & Son third with A. K. Williams.

For twelve blooms of any dark velvety crimson Rose Horace Vernet was first and second as staged by Messrs. Harkness & Son and Mr. B. R. Cant, and Louis Van Houtte third from Messrs. A. Dickson & Son.

There were seventeen entries in the class for twelve blooms of any light Rose, exclusive of white, Messrs. J. Townsend & Son taking first place with Mrs. John Laing, followed by Mr. B. R. Cant and Messrs. D. Prior & Son with Her Majesty.

Mr. B. R. Cant staged Madame Cusin in superb form in the class for twelve blooms of any Tea or Noisette, and received the first prize. Mr. G. Prince was second with The Bride, and Messrs. F. Cant & Co. third with Madame de Watteville.

For twelve single trusses of new Roses there were eight competitors, of whom Messrs. A. Dickson & Son were placed first with Countess of Caledon, Tom Wood, Lady Clanmorris, Ulster, Mrs. Mawley, Mrs. W. J. Grant, Elleen, Killarney, Daisy, Mrs. Grahame, First Cross, and Bessie Brown. Messrs. F. Cant & Co. were second, and Mr. B. R. Cant third.

There was a class also for new seedling Roses or distinct sports, of which three blooms and a ground plant had to be shown, and for which cards of commendation or a gold medal were awarded according to merit. Mr. W. Rumsey got a "card" for Mrs. Rumsey, a variety soft rose in colour and of good quality; Messrs. Paul & Son, Cheshunt, for Rose Royal Scarlet, a single variety of much beauty, while Messrs. A. Dickson & Son received the gold medal for Ulster, a lovely silvery rose coloured variety of the first merit.

Garden Roses.

Nurserymen.—The display made by the garden Roses, so called, was a very beautiful one—or rather, two beautiful ones, for the classes were divided, and the interest in these Roses with the public is evidently growing rapidly, if we may judge by the admiration they elicited. It is to be hoped that at future shows the blooms in this section will be staged together, so that their full beauty may be appreciated by all.

In the class for thirty-six bunches, distinct, not less than three trusses to a bunch, Messrs. Paul & Son were first. They staged, amongst others of great beauty, Crimson Rambler, Madame Falcot, Perle d'Or, Rosa Gallica, Rosa Mundi, Madame Pernet Ducher, Carmine Pillar, Bardou Job, Marquise de Salisbury, and Rose Apples. Messrs. G. Cooling & Sons, Bath, were second.

Mr. C. Turner arranged a magnificent exhibit in the class for eighteen bunches of garden Roses, each bunch to be composed of not less than three trusses. The stand was composed of Bardou Job, The Garland, Madame Pernet Ducher, Rosa Mundi, Macrantha, Crimson Rambler, Felicité Perpetué, Commandant Beaurepaire, Laurette Messimy, Moschata alba, Cabbage Provence, Red Damask, Hebe's Lip, Common Moss, Madame G. Bruant, Perle d'Or, Reine Olga de Wurtemburg, and Anna Maria de Montravel. The second position was adjudged to Mr. J. Mattock, and the third to Messrs. J. Townsend & Son.

Amateurs.—In this section, Lord Penzance offers a silver cup as the first prize for eighteen bunches of garden Roses in distinct varieties, not less than three trusses to a bunch. For the third year in direct succession H. V. Machin, Esq., has secured the premier award, and each time it has been deserved. The stand comprised Camoens, Marie Pavie, Bandou Job, Cecile Brunner, Crimson Rambler, Mignonette, Laurette Messimy, Anna Maria de Montravel, Macrantha, Marquise de Salisbury, Perle d'Or, Bennett's Seedling, Madame Pernet Ducher, Rosa Mundi, Gloire de Polyantha, Homère, Paquerette, and Red Damask. Alfred Tate, Esq., was second for the third time in succession also. How will it be next year? It is evident both these gentlemen are fighters.

For six bunches, distinct, Mrs. A. F. Perkins was first with Madame Pernet Ducher, Triomphe de Pernet père, Madame C. Guinoisseau, Marquise de Salisbury Madame Plantier and Camoens. F. W. Campion, Esq., was second, and the Rev. J. H. Pemberton third.

Buttonhole Roses.

The class for twelve bunches of Roses suitable for buttonholes, not less than six varieties, nor less than three or more than seven trusses to a bunch, was very interesting. Mr. J. Mattock was a fine first with Gustave Regis, Rubens, Madame de Watteville, Madame Hoste, Madame Falcot, Hon. Edith Gifford, Anna Ollivier, Amazone, Niphetos, Ma Capucine, Comtesse de Nadaillac, and Innocente Pirola, each in good condition. Mr. G. Prince was second, and Mr. A. G. Green, Colchester, third.

Medal Roses.

As is customary the Society offered four silver medals for the best flowers in the show, two to come from the nurserymen's section and two from the amateurs. The best H.P. in the first named section was Horace Vernet, staged by Messrs. Harkness & Son; and the best Tea, Madame Cusin, shown by Mr. B. R. Cant. In the amateurs' division O. G. Orpen, Esq., with Kaiserin Augusta Victoria, was one of the medallists, the other being E. B. Lindsell, Esq., with Muriel Grahame.

Miscellaneous Exhibits.

The exhibits coming under this designation were very numerous, and several of them of excellent quality, but want of space precludes the possibility of our giving more than a passing reference to any of them. Messrs. J. Laing & Sons, Forest Hill, sent Begonias, Caladiums, Roses, and hardy flowers; Mr. M. Pritchard, Christchurch, hardy flowers; Messrs. A. W. Young & Co., Stevenage, Foxgloves, Canterbury Bells, and Poppies; Messrs. J. Cheal & Sons, Crawley, Violas, Roses, and other flowers; Messrs. W. Paul & Son, Waltham Cross, Roses, both cut and in pots; R. Wallace & Co., Colchester, Lilies and Calochorti; Mr. H. Foster, Brockhampton, Sweet Peas; Messrs. G. Bunyard & Co., Maidstone, Roses; Messrs. Paul & Son, Cheshunt, hardy flowers; and Messrs. G. Jackman & Son, Woking, Roses.

If the exhibition of the National Rose Society at Portsmouth were the smallest the Society has yet held, that which took place at the Crystal Palace on the 2nd inst. proved on the other hand the most extensive on record. The number of exhibition Roses staged in compe-

tition on that occasion amounted in all to 7200, or 1450 more than the average for the five previous metropolitan shows of the Society, and 100 blooms more than at the largest of those exhibitions—that of 1892.

There were over 100 exhibitors, whose exhibits, arranged according to the number contributed by each county, were as follows:—Essex heads the list with 71 exhibits, Surrey comes next with 51, then Middlesex with 35, Herts 34, Kent 32, Oxford 29, Notts 26, Somerset 20, Sussex 20, Worcester 19, Gloucester 15, Suffolk 15, Berks 12, Leicester 10, Wilts 8, Bucks 7, Devon 6, Hants (including Isle of Wight) 6, Derby 5, Northampton 5, Yorks 3, Bedford 2, Cambridge 2, Shropshire 2, Dorset 1, Stafford 1, and Warwick 1. In addition to the English contributions, seven exhibits came from Wales and eleven from Ireland, but, unlike last year, there were no Scottish-grown Roses. Seldom, if ever, has the Society held a more enjoyable exhibition.

The day, although dull, proved fine and cool, thus allowing the blooms to continue fresh and bright during the whole day. The general quality of the flowers was remarkably good, and particularly was this the case in the exhibits from many of the smaller growers. Moreover, there was at no time any overcrowding, so that the blooms could be inspected in comfort by both members and visitors.—E. M., *Berkhampsted.*

DEATH OF MR. W. K. WOODCOCK.

We much regret, as will many of our readers, to hear of the death of this well-known excellent gardener and worthy man. The sad event occurred on Friday night last at the Victoria Nurseries, Leicester, from pneumonia and a complication of diseases following a chill. Mr. Woodcock was for a considerable time gardener to Sir F. Mappin and Mrs. Mark Firth, near Sheffield, where he acquitted himself most creditably and well. He took an active part in the Horticultural and Chrysanthemum Society of Sheffield, as well as in gardeners' educational societies in the West Riding of Yorkshire, and his services were much in demand and willingly given in the reading of papers. He subsequently took a small nursery near Syston, devoting much attention to Chrysanthemums, and working with great diligence generally, eventually taking the Victoria Nursery, Humberstone. He was at the same time horticultural instructor for the Norfolk County Council, a position which he filled with satisfaction to all. He leaves a widow and grown up family, who, it is hoped, will be able to carry on the business as before, when they had the supervision of the experienced head. Mr. Woodcock was a genuine type of a British gardener, and we do not think was sixty years of age. We reproduce a portrait that was taken a few years ago.

Fig. 6.—Mr. W. K. Woodcock.

I am sure that many of the readers of the Journal will be sorry to hear of the death of Mr. Woodcock. He caught a chill while delivering a lecture in the open air at Norfolk, and, although he got better, he had a relapse from which he did not recover. I have known Mr. Woodcock for about ten years, and I have always found him a most kind, genial, and true friend. He was well up in all horticultural matters, and always tried to keep abreast of the times, and I am sure he will be greatly missed by a large circle of friends.—J. Lansdell, *Barkby Hall, near Leicester.*

RIPE STRAWBERRIES.

Illustrating the earliness or otherwise of the seasons by the ripening of the first fruits is always an interesting subject to me. To be brief, I will mention that last year our first fruits were ready for picking on the 6th of June; this year our first picking took place on the 23rd of the same month, just seventeen days later.

The following sorts were planted on the same day—namely, Royal Sovereign, Scarlet Queen, Noble, King of Earlies, and John Ruskin, and for all practical purposes ripened together. Although all alike in this respect, there is a great difference in the quality of the ripe fruit. Royal Sovereign takes the first place here for size and flavour; next I prefer Scarlet Queen, John Ruskin, King of Earlies, and last of all Noble. These remarks may not coincide with other growers in other districts on diversities of soils.

Last year several short notes appeared in the Journal on this subject; a few more this year would be welcome if the districts were indicated by the writers.—J. Easter, *Nostell Priory Gardens.*

OXYLOBIUM CALLISTACHYS.

This ornamental shrubby plant does not appear to be so generally well known as it might be, or it would be more extensively cultivated. Either as small plants for the side stages of the conservatory or as plants 4 feet high in large pots it would be found very useful. Like most of the Australian plants Oxylobiums require only ordinary greenhouse treatment, but to make them flower freely allow them enough sun to thoroughly ripen their shoots. They will be found to thrive best in a compost of fibry loam and peat of about equal parts, with plenty of silver sand added. Oxylobium callistachys (fig. 7) has bright yellow pea-shaped flowers produced in dense clusters, and is very showy, as are also many of the other species. The genus is a large one, but many of the species are not known in English gardens.

THE YOUNG GARDENERS' DOMAIN.

Lilium Harrisi.

Plants of Lilium Harrisi which have been forced for early decoration will now have ceased flowering, and many of them will be starting into growth from the base. Such plants as appear to be throwing up strong shoots may render capital service later in the season by cutting down the old stems and repotting in smaller sized pots, thus giving a fresh start. A cold frame will be suitable to grow them in and make dwarf plants. The stems do not attain much height when treated in this way, about 6 inches being the average. A very pleasing effect is obtained during the late season of the flower garden if they are plunged about the edges of herbaceous or mixed borders.

I have one bulb which has produced three stems, each bearing two fairly good blooms. It was forced amongst a number for the Whitsuntide decorations, but as the flowers were malformed it was cut down and allowed to start again from the bottom. Perhaps the deformity of the first blooms and cutting down the stem before allowing it to ripen would tend to increase the subsequent rapid growth.—R. A. Anderson, *Alnwick.*

Acalyphas.

For decorative purposes this is a very useful class of plants, their foliage contrasting effectively with Crotons and other kinds. If possible the tops of o'd plants should be selected for cuttings, as they, being stronger, grow more freely than side shoots. Insert them in thumb pots of light soil in early spring, and place in a brisk bottom heat, where they quickly emit roots. The plants may be soon afterwards placed in larger pots, using a compost of loam and peat, with a little leaf soil and sand. Peat is not used by some growers, but I consider it enhances the dark rich colour of the foliage. After potting place the plants in a stove temperature till they are established, when they may be either retained in the stove or arranged in the greenhouse. They last longer and assume a better colour with cool treatment during the summer, but they require a stove for wintering in. Liquid manure is very beneficial when the plants are root-bound.

It is a good plan to insert several cuttings at intervals during the summer, as the earliest plants get too tall towards the end of the season, while the latest last well through the winter, and serve for stock plants the following spring.

Acalyphas are sometimes employed for bedding, but the plants require to be strong and well prepared before being placed outside in the beds. Their worst enemies are thrips and mealy bug. A sharp look-out must be kept for these pests, and some approved insecticide promptly used, as the leaves are soon spoiled, and will drop, especially so in the case of attacks by thrips.—Balcarres.

Peaches and Nectarines.

Of late years these fruits have been more extensively grown outside than formerly, still they may be grown a great deal more yet with advantage to all concerned. Gardeners are becoming aware of the fact that excellent fruit can be produced by attention to cultural details from south, south-east, south-west, or east walls in various parts of England. The best aspect, of course, is south, although the finest wall of trees and fruit I have seen faces east. In ordinary seasons good-flavoured Peaches and Nectarines from this wall have turned the scale at 12 ozs. I am of opinion that more failures occur through neglecting cultural details than from aspects of walls. This is not so much a matter of want of knowledge on the subject, as sparing the necessary time to do what is needed at the right moment.

Elaborately made borders are not necessary for growing Peaches, as ordinary garden soil will in most cases suffice by adding clayey loam to light, and wood ashes, lime rubble, or road grit to heavy soils, rich borders being very detrimental to good fruit-bearing wood. The best time for planting is the autumn, selecting young trees without any trace of gumming. Plant about 6 inches from the wall, just deep enough to cover the top roots 2 inches. Make the soil firm by treading, and mulch with strawy manure to prevent radiation and conserve warmth.

The mode of training generally pursued is fan-shaped, which is perhaps the best, as it tends to arrest what would otherwise be exuberant growth. It is better to secure the growths and stems to wires, than to nail them to the walls, as the trees can be cleaned more easily, and the walls from constant nailings soon afford harbour for insects. If the disbudding is done properly, and sub-laterals stopped, very little pruning is necessary, with the exception of removing old

fruiting wood and rank growths. Strong growing trees should be root-pruned in the autumn.

Disbudding the growths is one of the most important features connected with successful Peach growing, and perhaps the most neglected. It should be done at intervals of about ten days, beginning as early as possible; first removing those growths which are badly placed, and also such strong growths as might be likely to develop into rankness, gradually reducing to the required number, erring rather on the side of sparseness than overcrowding, which is ruinous.—J. L. G.

(To be continued.)

Useful Winter Plants—Richardias.

In former papers I have treated on Salvias, Chrysanthemums, and Zonal Pelargoniums; I will now continue with the so-called Arum Lily, Richardia æthiopica, named after Mons. Richard, a French botanist. Richardia or Calla æthiopica is the best known and most grown of the genus. It is also called the Trumpet Lily and Lily of the Nile, though why the latter I do not know, as the plant is a native of South Africa. The spathes are much in demand for church decoration at Christmas and Easter, market growers often obtaining fancy prices at those times. Like enterprising men, as they are, they try to have as many flowers as possible at such seasons, when the wholesale price is a shilling or more each.

This Richardia is a most accommodating plant, succeeding well under various systems of culture. For growing for cut flowers I find planting out in trenches, prepared as for Celery, the best method, though they need scarcely be so deep and less manure may be used. Stand the pots of Lilies outside in a sheltered spot in May to harden, little water being required. The time to increase the stock is when the planting is done by dividing the crowns of large plants. Lifting is done about the first week of September, standing the plants under a north wall for a couple of weeks after potting. They may then be moved to a warm or cold house according to the time a large number of flowers are required.

A plentiful supply of water must be given after the plants start growing in the trenches, liquid manure doing good if used a few times. The soil used for potting the plants must be rich, as generally the roots nearly fill the pot, and may consist of loam two parts and a part each of leaf mould and horse droppings, with a sprinkling of bonemeal and soot. Liquid manure may be used with advantage. Water often after the pots are full of roots. Market growers usually use 5 and 6-inch pots for plants with one growth, and it is surprising how many flowers such plants give in a season.

For specimen plants in pots and tubs I prefer to dry the plants off, reduce the old ball, and repot in July, placing the plants where heavy rains may be warded off for a time. By placing them inside before those planted out flowers in quantity may often be had very early. The soil for potting specimens need not be so rich as for potting those planted out. Loam one-half, leaf mould one-fourth, and a fourth of horse droppings with a dusting of soot and bonemeal, or any of the artificial manures advertised in the Journal answering well.—W. T., *Ireland*.

Cucumber Culture (*continued from page* 11).

When the roots of the plants have pushed through the small mounds they are planted in, more compost must be added, and this should be of the same kind as before. Continue this process whenever the roots show outside the soil. Stop the plants the first time at the fourth joint, and afterwards always at the second.

Never allow the shoots to become crowded, but keep them thinned; and the fruit should also be kept thinned, allowing only one to each joint. All male flowers and tendrils ought be removed. The night temperature of the house should be about 70°, and may be allowed to rise to 90° or 100° in the daytime.

Winter Cucumbers.—The treatment for these varies somewhat from the summer, but the compost may be the same as mentioned for the summer plants, with a little charcoal added.

The main point is to get the plants well established before the winter months, and this can be done by sowing early in September. Allow the plants to grow about 2 feet before the first stopping, and afterwards stop at the second joint. Great care must be taken that the soil does not get too wet, or the plants will fail. Syringing should only be done on bright days, and then only once, for damping the paths will afford sufficient atmospheric moisture. A night temperature ranging from 65° to 70° will be sufficient for them.

Cultivation in Frames.—The first thing is to prepare plenty of litter and leaves. These should be well mixed, and a bed made at least 3 feet thick, and 2 feet wider than the frame. Tread the bed firmly, and set the frame on it with a southern aspect. Place a ridge of soil in the frame, and in this, when the steam from the bed is exhausted, insert the plants at a distance of 3 feet apart. A light shading will be necessary during the hottest part of the day, and adequate air must be afforded. Like Cucumbers in houses, they require plenty of atmospheric moisture, and the frame should be damped morning and afternoon. No trellis will be required, but the shoots should be stopped at the second joint, and also kept thinned out.

As to varieties there are many, and each grower has his favourite, but for general use I think Telegraph has yet to be excelled. Green fly, thrips, and red spider are the chief enemies of the Cucumber, and as soon as these put in an appearance fumigate with tobacco, or syringe with a solution of quassia. Eelworms are dreaded enemies, and plants that are attacked soon succumb. They live in the tissues of the roots, and from thence derive their nourishment. The safest way to be rid of this pest is to take the plants up at once and burn them, then clear the bed thoroughly out, and make a fresh start.

Whilst visiting a friend last summer he took me to see a house of Cucumbers, which he said he has cleared from an attack of eelworms. He had used a mixture of gas liquor, soluble phenyle, sulphate of iron, and kainit. The plants instead of being "droopy" presented a healthy appearance, and were bearing abundance of fruit.—Elveden.

Humea elegans.

Humeas rank amongst our best plants for decorative purposes. Whether in the conservatory, flower bed, or drawing room, they show their grace and beauty to advantage.

The seed should be sown in July or early in August, in pans, clean and well drained, in a mixture of well sifted turf and leaf mould, with a little sharp silver sand added. Place the pans on shelves near to the glass, in a house with the temperature ranging from 65° to 70°. As soon as the seedlings are large enough prick them into boxes, and when well rooted pot singly in 2½-inch pots, using the same mixture as before. Keep the plants near the glass to prevent their becoming drawn, and grow them steadily in a cool temperature.

Fig. 7.—Oxylobium callistachys.

They will require another shift later on into 5-inch pots, and when these are well filled with roots they may be transferred into the pots in which they are to flower. For the final potting 8-inch pots may be used, and they should be clean and well drained. Pot firmly in a compost of fibry loam, leaf mould, with broken charcoal, and coarse river sand added. Humeas require very careful treatment in the way of watering. If the soil become in any way sour or waterlogged the roots decay, leaves turning to a sickly yellow colour in consequence, and flagging; when this occurs the plants may as well be thrown away at once, as recovery is almost hopeless.

For bedding purposes Humeas are well adapted. They make a charming display when planted alternately with Dahlias Formosa, or Lady of the Lake, or in sub-tropical bedding. After they have served their purpose in the beds or conservatory, the plants may be cut down and dried, and their inflorescence will be acceptable for room decorations in winter.—E. J. B.

FRUIT FORCING.

Peaches and Nectarines (*Early Houses*).—The trees having been cleared of the fruit, cut away the wood on which it has been produced to the successional shoot at the base, and stop growths making more than 12 to 14 inches of wood required for bearing next year, always excepting extensions, which may be allowed to grow where there is room. Pinch the laterals at the first leaf and to subsequent as made, thinning where crowded. Syringe forcibly to expel red spider, and if necessary apply an insecticide. Admit all the air possible, and where practicable withdraw the roof lights from the earliest forced houses. Maintain a proper condition of moisture in the outside as well as inside borders.

Succession Houses.—Where the fruit is ripening syringing over the fruit must cease, air being given day and night so as to prevent moisture being condensed on the fruit, and thus inducing "spot" to affect and spoil the finest specimen. Moderate air moisture, however, should be secured by damping the paths and borders in the morning and afternoon, not neglecting to afford due supplies of water at the roots, with light mulchings, especially on light soils.

Where the fruit is swelling syringe morning and afternoon, not allowing red spider to get the least footing, or it will increase to the prejudice of the current and succeeding crop. Expose the fruit to the light by drawing the leaves aside, shortening them or raising on laths, with the apex to the sun. Keep the growths fairly thin and tied down, not too tightly, as they advance, stopping next year's bearing shoots at about 14 inches, if they exceed that length, and pinching the laterals to one leaf as made. Extensions may be trained in full length as space permits, but avoid crowding, and maintain, as far as possible, an even growth throughout the tree. Afford liquid manure or top-dressings of fertilisers after making the border moist, and wash in moderately to weakly trees, not neglecting the watering. A little air constantly will do much to prevent scorching, and the enlarging of the openings early in the morning will secure a long day's work of elaboration, always provided the temperature be not lowered but advances with the sun heat.

Late Houses.—It is only possible to have fruit very late by keeping the houses as cool as possible during the hot summer months, ventilating day and night, but not in windy weather, this causing the current to rush through the structure and dry the atmosphere excessively. Nothing is gained by that, but often a rich harvest of battered leaves and a plentiful crop of red spider. This pest must be laid low by forcible syringings in the morning and late afternoon, the trees having also plenty of water and nourishment at the roots, with mulchings of partially decayed lumpy manure, and these kept moist will keep the roots near surface. Avoid, however, heavy mulching, about an inch thickness sufficing, adding to it from time to time. Do not allow too many fruits to remain for the crop, but thin them betimes, leaving about a fruit to each square foot of trellis covered by the trees.

Pines.—*Starting Suckers*.—In order to accommodate these from the early section of summer-fruiting plants, a fermenting bed in a low house or pit must be got ready, and its heat steady at 90° about 6 inches from the surface. Take the suckers from the parent plants carefully, trim the base smoothly, and place directly into 5 or 7-inch pots, according to the size of the suckers, and water once in order to settle the soil about them. Good fibrous loam, torn up by hand, without any admixture, is the most suitable compost; embed it firmly in the pot, so that a sturdy growth may be insured in the plants. Keep the suckers rather close and shaded for a week or ten days, sprinkling through a fine rose syringe once or twice a day, according to external influences. When growth takes place ventilation with less shade is desirable, but this must be proceeded with gradually until the growth is well decided and inured to the sun; then accord them ordinary treatment.

Placing in Fruiting Pots.—When the suckers are well rooted they should be transferred to the largest pots before the roots become matted together. Queens and Black Jamaica should be given 10-inch pots, other sorts 11 or 12 inch, using fibrous loam, but more lumpy than for suckers, adding a sprinkling of steamed bonemeal; and to prevent worms entering the pots either use worm excluders or a handful of soot or wood ashes sprinkled over the drainage. Pot firmly, and accelerate growth as far as it is consistent with a sturdy habit.

Strawberries in Pots.—For securing sturdy runners early planted ones of last year afford them soonest and best, especially when not overcropped and not neglected for watering. The plant should have shown blossoms, because runners from fruitful plants always turn out better than those from fruitless strong-growing parents. The runners may be (1) layered in the fruiting pots, (2) on turves, and (3) in small pots. All three plans are good. In any case it is essential that the first runners, which give the finest plantlets, should be selected, and that they be induced by watering to emit roots freely at once, so that they may by judicious attention develop into sturdy plants and form good crowns. If layered into the largest pots they need not be detached until thoroughly established. Those layered in turves or 3-inch pots should, as soon as rooted properly, be detached and stood in a shady place for a few days, preparatory to shifting them into the fruiting pots. These may be 5-inch for very early work and 6-inch for succession, with 7-inch for late forcing. Nothing is gained, however, by using large pots.

For very early use La Grosse Sucrée is unrivalled, as it both sets and swells the fruit well, this being of good size, colour, and quality. Vicomtesse Hericart de Thury also sets, swells, and finishes fine glossy fruits of good flavour. Royal Sovereign cannot well be termed a first early, but is excellent as a second, or where few are grown may take the former position. It is everything that can well be desired in cropping, colour, and quality. If the Keen's Seedling be had true it has merits that are always appreciated for home use, the deep colour and fine quality always pleasing. Similar remarks apply to Sir Harry and President, but neither travels well. Noble has much to recommend it for cropping and size, but there it ends; and Auguste Nicaise, though much brighter in colour and in flavour, is considered coarse by some, but both are esteemed for supply and appearance. Sir Joseph Paxton yields to no other for affording full crops of large and first quality fruit as a mid-season or rather late forcer. For brightness of colour Sir Charles Napier stands supreme, not any shine like it, but it belies the looks in quality. Lucas, a very compact grower, produces abundance of the choicest quality fruit, and gives a fitting foretaste of British Queen, as also does Gunton Park. Dr. Hogg and Cockscomb, with La Constante, run the "Queen" hard for quality, yet spite of all it remains supreme. Waterloo as a darkie of good using quality may have place, but some do not, while others appreciate very dark-coloured fruit.

The pots must be clean inside and outside, have a large crock over the opening, three or four of lesser size, and some smaller still, so as to form about an inch of drainage. This should be secured with the rougher parts of the compost rammed tightly down. Turfy loam, strong rather than light, must form the staple of the compost. Break it up roughly, adding about half a pint of bonemeal, pint of soot, and a quart of wood ashes to each bushel of soil. If these are not at hand, the advertised fertilisers answer equally well, following in each case the instructions given with them. Let the compost be moderately dry when used, for if wet it will shrink after potting, leaving the sides of the pot. Bring the soil in the pot up to the required height, ram it firmly, and finish, so that the base of the crown will be about half an inch below the rim, which must be left clear for watering, allowing a little more for the large size of pot. Stand the pots on a hard base in an open situation, but sheltered from strong winds, with sufficient space between them to allow the full exposure of the foliage. Give water as required, and sprinkle the foliage for a few days after potting. If this be followed each evening it greatly assists the plants. When the roots are working freely in the fresh soil copious supplies of water will be needed, and always give sufficient to moisten the soil through to the drainage. The plants must not be allowed to flag, and the soil ought not to be soddened by needless waterings. Remove runners and weeds as they appear.

THE KITCHEN GARDEN.

Asparagus.—Abundance of sunshine has so materially hastened the crops of Peas that there ought to be no further excuse for continuing to cut Asparagus shoots, even in the latest districts. It should always be remembered that the foundation for next season's success is laid during the preceding summer. Unless the plants form strong growths moderately early in the summer, and these are taken good care of, by roughly supporting with stakes and raffia, or Pea stakes, if need be, there will be no strong basal buds formed, and no resulting fat shoots the following spring. Where growths come up very thickly none of them will be extra strong, and it pays to thin them out in June or early in July. More good can also be done now in the way of feeding with liquid manure or by washing in a surfacing of salt and guano or special manure than can be done by heavy autumnal or spring dressings of manure. A summer mulching with short strawy manure acts beneficially, as it conserves the moisture and keeps down weeds. Too often these are allowed to get the upper hand during a busy season, and the consequence is a legacy of seeds, that proves to be a great nuisance in after years. They must be kept under now.

Runner Beans.—On no account delay staking the late rows till the plants are all entwined round each other. Those grown thinly, or nearer 12 inches than 4 inches apart, will be found to be the last to fail in hot dry weather, and, as a rule, much the heaviest croppers. Regulate them early, and if comparatively short stakes are used top the running growths directly they have reached the ends of these. Those to be grown without stakes ought to be gone over every week, and have all running growths cut hard back. Unless this is done they will quickly become matted together, and the crops will be of little value accordingly. Mulch with strawy manure for the double purpose of keeping the ground moist and the pods clean.

Cabbage.—Leaving old stumps to form fresh heads has a most impoverishing effect upon the ground, and is also objectionable where perennial weeds are apt to be troublesome, but they frequently produce very acceptable supplies of tender young hearts for autumn and winter use. Coleworts or small quick-hearting Cabbages if grown in quantity may, however, prove more profitable and less impoverishing. It is not yet too late to sow seed of the popular London Rosette or other favourite small varieties, but a fortnight earlier would, perhaps, have best met the case; a bed of small plants being ready to plant thickly in close succession to autumn-sown Onions, Garlic, and Shallots. The plan of sowing the seed where the bulk of the Coleworts are to grow

is a good one, and the best that can he followed now. If the ground to be devoted to this crop is poor dig in manure freely, making the soil firm and fine at once. Drills to be drawn 15 inches apart, and watered, if dry, prior to sowing the seed thinly. Eventually thin out the plants to 6 inches or even less apart, and the result will be a heavy supply of neat hearts of excellent quality, because quickly grown.

Leeks.—These are among the most reliable of all winter vegetables, and are proverbially hardy. They can be grown cheaply and simply on well manured, deeply dug borders. Supposing the plants were raised in the open they ought now to be 10 inches or more high, and quite large enough to put out. Give the ground about them a good soaking of water to facilitate drawing them without breaking the roots unduly, and after they are drawn lightly shorten the tops. Holes 8 or 9 inches deep, 1½ inch across, and 12 inches apart each way to be formed with an ordinary stout dibble, and a plant dropped in each. The holes not to be closed, and a watering will fix the roots. All that is further needed is to water once more if the weather keep very hot and dry, and to keep the surface free of weeds. No moulding up to blanch the stems is necessary in this case.

Endive.—In order to have extra fine, moderately early Endive. seed ought to be sown either late in June or during the first fortnight in July. The plants do not move well in hot, dry weather, and in common with Lettuce the seed may well be sown where most of the plants are to develop. As it happens, there are few vacant plots of ground in most gardens at this time of year, and the Endive has to be raised in beds accordingly. If the seed is sown thinly in shallow drills 6 inches to 8 inches apart, and a portion of the plants resulting are planted out when large enough, the rest may be left where they are. Being somewhat thick, they will press against each other and close up, an excellent supply of early, well-blanched hearts resulting.

Tomatoes. — Those planted out against walls and in sunny positions generally have made good progress, and most probably will continue to do so, provided they are not neglected in any way. Unless extra leading growths are wanted for furnishing blank spaces, all but the most central shoot should be early cut or pinched out, and the requisite training he done before the plants become set crooked. Early Ruby and a few other varieties are apt to form coarse central flowers, and these if retained are invariably followed by rough ugly fruit. Pinch them out as soon as this can be done safely, and this will greatly benefit the smaller later flowers, adding considerably to the value of the crop. A good soaking of water once a week will not be wasted on the plants in hot, dry weather, and a mulching of strawy manure will also do good.

Turnips.—Early in July is a good time to sow Turnip seed in quantity. In some seasons and gardens it not unfrequently happens that this sowing results in the production of the most serviceable supply of roots for the winter, especially where the value of the Chirk Castle Blackstone is realised. A cool site is desirable, and the ground well prepared, good Turnips seldom being had from poor soil. Open drills 15 inches apart, water if dry, and sow the seed thinly.

PLANT HOUSES.

Crotons.—Pot all free-growing plants that are well furnished at the base into 7 and 8-inch pots, or even into larger if plants in these sizes can be employed for furnishing. Plants that have become too tall may have their heads re-rooted, so that well coloured side shoots will be produced for rooting later in the season. Where quantities of decorative plants with ornamental foliage are needed in rooms during the winter months too many Crotons in various sizes cannot well be produced. We have always a good stock of highly coloured plants in 2 and 3-inch pots, which are most useful for association with Ferns, Mosses, and other dwarf-growing plants. Do not shade the plants, but expose them fully to the sun, so that their rich colours can be developed. Syringe them liberally, and close the house early in the afternoon. Give a little artificial manure to the surface of those that it is necessary to keep in certain sizes when they are full of roots.

Dracænas.—Where plants are becoming too large and have lost their lower leaves the stems may be cut and mossed. In a close moist atmosphere they throw out roots quickly, and may he taken off with good balls, and placed at once in 6 and 7-inch pots, according to the variety. If placed in the shade for a fortnight well-furnished plants are again produced. Where narrow leaved kinds are appreciated for table decoration superba is one of the best. To have really good plants those raised from portions of the stem need to be grown strongly and the top re-rooted before plants can be had in their best condition. The same remark applies to Guilfoylei, and when well grown it is a very handsome table plant. To colour these plants highly they must be exposed to plenty of light, but this must not be overdone, or their foliage becomes too highly coloured, and is liable to go had at the points. Young stock raised from portions of stem this spring and well established in 3 and 4-inch pots should be placed into larger ones. It is a great mistake to allow plants that it is intended to grow on to become root-bound before they are repotted. Plants checked by this cause seldom do any good afterwards. These plants need careful watering for a time after potting until they are rooting freely in the new soil. The same treatment should be given to green varieties that can be grown in a lower temperature; but if well-developed plants are needed as soon as possible they may be grown in heat during their early stages, or until they are large enough for the purpose for which they are required. Dracænas do well in equal parts of fibry loam and leaf mould, with one-seventh of manure and a liberal quantity of coarse sand. Peat may be substituted for the leaf mould if plentiful.

Allamandas.—Plants growing in pots will have filled them with roots by this time. If they are to continue producing the largest size flowers a liberal top-dressing of manure must be given them, the roots will soon take full possession of it. Liquid manure may also he given in a weak state every time the plants need water. Do not allow them to become dry; the object should be to keep them growing, then they will continue to flower. Do not shade the plants, but grow them fully exposed to the sun. The reason these plants make vigorous growth, and often fail to flower profusely, is due to overshading.

Stephanotis floribunda.—Plants that have been trained upon trellises and have done flowering should he taken off and cleaned. If they are to flower well another year train the growths under the roof of a light house, where they will he fully exposed to the sun, and where air can be given freely until September. In this position the wood will become thoroughly ripened, and the plants will flower well another year. If kept closely trained upon trellises the whole season the wood has but a poor chance of being well ripened. Plants that are growing freely may have weak stimulants every time water is needed if the pots in which they are growing are full of roots. If mealy bug exists upon the plants syringe them occasionally with petroleum and water, 3 ozs. of oil to 4 gallons of water. Shade for a few days afterwards until the oil has heen evaporated.

Clerodendron fallax.—Plants raised from seed and well-established in small pots may be placed into 5 and 6-inch. Once they are fairly established in these pots and have been gradually hardened they will do in cold frames, provided they are kept close and closed early in the afternoon, so as to run up the temperature.

Asparagus plumosus.—Young plants raised from cuttings and well established in thumbs may be placed into 4-inch pots. In this size they will make bushy little plants. Those in 4-inch pots may be placed into 6-inch. This variety in small pots is very useful for decoration, especially for grouping with other plants in large conservatories.

Fittonias.—A good stock of these may be raised in small pots. They are useful during the winter. When once they are rooted they will grow freely under the shade of Crotons, Dracænas, and other plants where it is warm and moist.

Panicum variegatum.—Well furnished plants in 4 and 5-inch pots are always useful where furnishing is carried out on a large scale. A number of pots should be made up at once by inserting cuttings thickly into the sizes required. They root readily in any warm, moist, shady place.

THE BEE-KEEPER.

WORK IN THE APIARY.

ALL will now be life and bustle in the apiary. The weather, unfortunately, has not been altogether favourable for honey production, as only one really bright day has been chronicled since my last notes. There have been several days when the sun shone out brightly for an hour or two, then it became cloudy for the remainder of the day. There have been heavy thunder showers at intervals, which, although beneficial to the growing crops, prevent the bees from storing a large surplus.

It is interesting to observe bees on the first sound of distant thunder—how they hurry home; sometimes the air is quite darkened by masses of bees anxious to reach their hives before the storm comes. Many are lost when heavy showers come on without much warning, being beaten down and unable to rise again with their load. If the storm is of short duration, and the sun shines brightly afterwards, some will be able to dry themselves and rise on the wing again, and be little the worse for their drenching.

It is surprising the amount of work a strong colony of bees will do during a few hours of bright sunshine at this season, and I find that the stronger the colonies the harder the bees appear to work. They mix readily during the summer months without sprinkling with either flour or syrup. It will at once be seen how easy it is to make strong colonies when there are extra stocks from which to obtain frames of brood and bees. The present season shows the wisdom of working them on these lines, as with a few hours' sunshine a surplus will be stored which may otherwise have been wasted, as weak stocks would be unable to collect it in the time.

REMOVING SECTIONS.

It is advisable when working for comb honey in sections to examine them every two or three days. Although the weather may be dull for a few days after a spell of fine weather, work will be still going ahead in the hive. This is more apparent in a stock that is being worked for comb honey than for extracting purposes. When the honey is first collected from the flowers it is not all stored at once in the supers, but is placed in empty cells wherever found. During the night or dull days it is removed into the supers, and when properly ripened is in due course sealed over. Directly this has taken place the sections should be removed, or the bees by constantly passing over them will cause them to become

discoloured, and good sections will soon deteriorate in appearance, and will be classed as second rate, whereas through judicious management they would have been of superior quality.

If a second crate of sections has been placed under those that were partly sealed over, the latter will now be ready for removal from the hive. If a carbolic cloth is laid over the top of sections for a few minutes the bees will beat a retreat down into the brood nest. The sections may then be lifted out, and any stray bees remaining brushed off with a feather. Any sections not properly sealed over may be replaced in the crate again, and the empty spaces filled with the more forward sections from the lower crate, and the latter again filled with empty sections.

The two crates are then placed as before, and should the weather be favourable and honey plentiful they will probably be filled before the end of the season, as bees do not remain idle in their hives during dull weather, but, as is shown in the case of sections of comb honey, they remove the honey from the cells where it is not required, placing it in the section, and sealing it over; they have then space at liberty to store a surplus when a favourable change in the weather comes.

Extracting Honey.

Working for extracted honey requires similar methods in the early stages to that for comb honey; afterwards it is somewhat different. If the full frames are left in the hive until they are quite sealed over, unless an extra storey were placed on the hive as in the case of sections, much valuable time would be lost, and in all probability the bees would swarm, and that, too, just at a time when they are most required as workers in storing a surplus. It is not necessary for the combs to be fully sealed over when required for extracting purposes; all that is needed is that the honey be thoroughly ripe, and it is usually so when the frame is about half sealed over. A little practice will enable the bee-keeper to know when it is in a fit state for extracting. If the honey is unripe it will ferment and be useless, and if placed on the market even before it shows sign of fermentation it will give the bee-keeper an unenviable repute, and he will afterwards have a difficulty in finding a market for his produce.

If fermented honey is fed back to the bees it will often cause dysentery, so it is worse than useless, and bee-keepers have only themselves to blame if their honey is not of the first quality. Of course, one cannot always command honey in all seasons of the quality of that obtained from White Clover, as it varies considerably from the different varieties of flowers, but each should be obtained in perfect condition. Honey should always be extracted early in the morning, so that all has had the advantage of being at least a few hours in the high temperature of the hive.—An English Bee keeper.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," *8, Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Fine Strawberries (*G. R. Allis*).—We are much obliged by the fine specimens of Leader and Monarch, and note that the first named ripened with you on the same date as Royal Sovereign—June 14th. We agree with you that Ganton Park is a good firm Strawberry, and travels well. Your expressions of approval of our extra number in honour of the Queen are appreciated. We have never published an issue that has met with such a welcome acceptance.

Roses for Town Gardens (*F. W.*).—On page 23 you will find an excellent article that will be of more service to you than the brief reply that could be given in this column.

Mustard and Cress (*A. E. B. and T. C.*).—The number containing the article you require has been out of print for some time. We propose, however, to republish the notes, as we feel sure they will be of assistance to others as well as you.

Cheap Work on Greenhouse Management (*M. D*).—We know of no work in which so much sound information is given for a shilling as in the *Primer* on "Greenhouse and Window Plants," by the late Mr. Charles Collins, and published by Messrs. Macmillan & Co. It can be obtained through a bookseller. Some plants are more fully treated in the *Garden Manual* (which also treats on fruit and vegetables), and can be obtained post free from the publisher, 171, Fleet Street, for 1s. 9d. It is one of the cheapest works on gardening extant, and has had a very large sale.

Strawberries Diseased (*J. W.*).—The berries and flower scapes are overrun by a mould, sometimes referred to as Botrytis vulgaris—a common mould on decayed fruit and other dead vegetable matter, but the web-like and felted mycelium is that of Botrytis cinerea, var. sclerotiophila, *Sacc.*, and the "fruits" it bears very sparingly the conidial condition of the Potato, Tomato, Carrot and Parsnip smother fungus, Sclerotinia sclerotiorum, *Mass.* The fungus produces small black bodies (sclerotia), and these pass the parasite over the winter, whence spring the conidial condition again, and infest the parts of plants already decayed or in a weakened epidermal condition from excess moisture acting on parts containing a large amount of watery or nitrogenous matter. We can advise nothing but cutting of the older leaves with the diseased trusses, burning them, and dressing the plants with basic slag phosphate, 7 lbs. per rod, after clearing away the weeds and rubbish. In the autumn apply kainit, 3½ lbs. per rod, and supply the dressing of manure then, if any be applied, or point the kainit in lightly. In the spring use bone superphosphate, 1½ lb. per rod, mixed with three-quarter lb. nitrate of soda, following when the plants are showing flower, with another application of nitrate of soda, crushed fine, and kept off the plants, three-quarter lb. per rod. Apply the litter for keeping the fruit clean then, so that it may get washed and be sweet. We have found this procedure very effectual against fungi, but the greatest care should be taken not to damage the fruit, and all mouldy ones should be cleared away and burned, for it really is in these that the fungi first find a nidus, and then spread to sound fruits, especially if the weather prove damp. We have also found great benefit from dusting the plants by means of bellows apparatus just before they come into flower, with a preparation of lime and sulphate of copper, such as anti-blight or fostite. The fungicide must not be applied later, or there is danger of its remaining on the berries to the prejudice of their use—that is, injury to the health of those eating them. To guard against this we have used a mixture of air-slaked chalk lime with one-tenth of flowers of sulphur against these forms of mould, applying by means of a bellows apparatus just before the plants come into flower, and again directly the first fruits were set.

Melon Fermenting (*A. A.*).—The very fine solid fruit has the flesh permeated by the mycelial hyphæ of a fungus, which may be readily seen with the suckers (haustoria) in the cells. It is Gloeosporium fructigenum, commonly called ripe rot or bitter rot, as the mischief does not appear generally till the fruit is nearly mature, imparting to it a bitter flavour. We have often found this disease in Melons, usually attacking the white-fleshed varieties, Colston Bassett being liable to it, as are also the highly flavoured green-flesh, such as Exquisite. But it attacks all varieties more or less at times, and almost invariably the hard-rinded, very solid-fleshed fruits. There are no "fruits" of the fungus, but, if you like to keep a Melon for the purpose, they will ultimately appear, and you may see small black pustules, which contain the fructifying bodies, these bursting through the apex and liberating the spores. The fungus germ-tube appears to enter the fruit at the blossom end, but when we have not been able to ascertain; but the injury does not become apparent until the fruit changes for ripening, when that process, instead of proceeding, seems to be retarded, the flesh decaying from the inside. Sometimes, however, the fruit decays externally from a central spot, and this spreads till the fruit is ruined. The most common cause of its prevalence in Melons is high concentration of the juices in the earlier stages of swelling. It is incited by a deficiency of water then, and later on supplying too plentiful supplies with too much atmospheric moisture or not enough air to allow of effective evaporation. By cause we mean cultural, for the fungus is really the sole cause, and it gets its chance as the fruit becomes somewhat soft at the blossom end, the rind being thinnest, hence the germ-tube finds entrance, and the mycelium spreads "fast and furious" in the tissues. There is really no remedy, for the mischief is done before it is discovered, and we know of nothing better than using lime with the soil, and feeding with bone superphosphate, nitrate of potash, and sulphate of magnesia, in mixture, six, three, and one part respectively, 2 to 4 ozs. per square yard. By attending to free growth in the early stages, with drier conditions later on—say, from netting, not parching at the roots, the fungus has a very poor chance. at least, such has been our experience. Burn affected fruits, clear out and thoroughly cleanse the structure, using a little sulphur in the whitewash for the walls, about a handful to a pailful. A light brushing over of the hot-water pipes with a cream of sulphur and skim milk is useful against the fungus, as the fumes kill the germ-tubes of the spores.

Model Gardens at Shows (*T. R.*)—The miniature models of which you speak are nearly obsolete, and some which are produced are miserable poor objects of what gardens should be. The size you mention is very small; but whatever the size, all the features, such as walks, beds, borders, or whatever may be represented, must be in due relative proportion, and the work must not be "roughly done;" on the contrary, it cannot be done too carefully and well.

Lilium candidum Leaves Diseased (*A. Mc*)—The bulbs are perfectly clean, indeed, very fine and sound. This is important, as indicating that the fungus on the leaves has not reached the roots, where its mycelium does great mischief, outgrowing them and causing their decay. We congratulate you on this, for the parasite is very malignant to most Liliums. Dusting with a preparation of sulphate of copper with lime, 10 per cent. of the first, is a good preventive against the disease spreading. We should simply remove the withered stems and burn them, as they may probably when decaying produce the conidial form, and the disease thus be carried over a wide area. Keep your plants healthy, using manure only in a thoroughly decomposed state, and then the Lilies will hold their own against their parasites, especially if the cultivator promptly adopts repressive measures, and affords sustenance enabling the plant to resist its enemies successfully. Use mineral matter, especially lime, as this quickly reduces organic matter into inorganic, the first being needful to the parasite, and the latter the stability of the host against it. We should not destroy the Lilies.

Black Stuff on Greenhouse Plants (*Mercy*). — The "black stuff" on the leaves is the filthy excreta of aphides or "green fly," taken possession of by a fungus, commonly called black mould, Fumago vagans, which does injury by its overgrowths, hindering the elaborating functions of the leaves, causing them to become pale in colour, and to fall prematurely. The cause of the mischief is the aphides, and these must be destroyed before there can be any relief from the "black stuff." Any of the advertised insecticides would rid you of the green "flies," or if you do not like a liquid application, which would be best, as it would destroy the fungus as well as the aphides, you may fumigate the house with tobacco paper on a calm evening, repeating occasionally until the pests are destroyed. As a home-made preparation procure tobacco juice, sold by horticultural sundriesmen, and add one part to five of water, in which 2 ozs. of softsoap has been dissolved, to every gallon, apply with a syringe in the evening, and wash the plants with clear water in the morning. Tobacco powder may also be dusted on the affected parts, and this, from the sulphur it contains, acts well on the fungus, whilst the tobacco kills the aphides. If applied in the afternoon the powder may be washed off in the evening, or if used at the latter time syringe in the morning. There is no preventive other than thorough cleanliness, keeping a watchful eye on the plants, and on the first appearance of the pests promptly take measures to prevent their spreading by destroying them.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*P. S.*).—Your specimens were not in a proper condition for naming, and moreover had no numbers attached, so that it would be impossible to discriminate. Send fresh ones properly numbered, and addressed and packed as suggested above, and we will endeavour to assist you. (*C. O. A.*).—1, Adiantum trapeziforme; 2, Asplenium bulbiferum; 3, Pteris cretica albo-lineata. (*S. R.*).—Chrysanthemum maximum. (*A. D.*).—Erigeron philadelphicus.

AN ENGLISH CHICAGO.

AMONG the middle and lower classes of England cookery has not reached its zenith. It is by no means a fine art. We like viands that cook themselves, as it were; we scorn foreign kickshaws, and prefer plain boiled and roast. For emergencies we are unprepared. Certainly there is the tough steak and the leathery chop, but even these fail in outlying districts, and we fall back upon the universal ham and eggs or bacon. Now these are very good, pleasant victuals if the eggs are sound and the bacon home-fed. The egg question can be left for another time, it is of the "genus" pig we would speak.

There is, we think, more variation in the quality of ham and bacon than anyone could imagine. The raw material must be right in the first instance, the breeder wants a profit, and the customer wants something toothsome and eatable. To our mind there is a great deal of bacon on the market that in the shape of an old sow has weathered many a blast. Anyone who manipulates a pig when turned into pork can soon tell the difference between a tender middle-aged pig and the venerable matron. Cut up the fat for rendering into lard, prepare the liver for the fry, pick out the tit-bits for pies, and the knife soon reveals the age. Now we hold that such ham and bacon, cook them as you may, are always more or less stringy, and do not melt in the mouth as they should do.

Then, again, there are various breeds, and each one has his special fancy. We hold that a middle-sized pig is always to be preferred to those monsters of the sty so often seen. In pigs of that description there is so much waste—the thick end of the flitch is almost uneatable. There is not a gleam of lean meat, and pounds of good meat are a perfect nightmare to the careful housekeeper. There is a certain amount of this fat that can be used to form an armour for roast poultry or game, but this is only

a small quantity of the whole. We find it the best course to take a straight piece off before salting, and we "render" it with the rest of the inside fat. Then, again, in the hams. Who but knows that rounded end that makes so good a beginning, and must at the last be supplemented with lean beef or potted meat to make it go down at all?

There is a great deal of meat spoiled every season by (1) undercuring, (2) overcuring. We do not care to kill our pigs too early in the season; in close muggy weather thick sides and big hams have no chance of curing properly. Some people have such an exaggerated idea of the value of saltpetre. True, it imparts a beautiful red tinge, but it also is very hardening in its effect on the lean of the meat. A pennyworth is quite sufficient for a 30-stone pig. The salting process is often hurried, the meat not turned and rubbed sufficiently often, and the curing room close and damp.

No good bacon can be made unless there is ample time allowed for gradual and steady drying. How much "reasty" bacon is trimmed off rashers and boiling pieces every year simply because the drying room has been too hot and the process too long. Much bacon is lost every year through the attacks of the bacon weevil Once that wretched insect gets into a chamber it is almost impossible to eradicate it.

We recommend in cases where there is the slightest suspicion of such an enemy that the bacon and ham, immediately it is dried should be coated with limewash, sewn up closely (not tied) in cotton stuff, and limewashed again.

Some people keep their bacon in chests full of lime. It is certainly safe from the attacks of mice and insect life, but a good deal of "outside" is made. Some, again, prefer malt culms; but these, to our thinking, impart an unpleasant flavour.

Our English market has of late years been flooded with millions of tons of foreign produce, which, being sold at a low price, has met a ready market. It certainly is sound meat, but so tasteless and insipid in character; this is possibly from want of proper drying. It also has another great fault—it wastes so in the cooking. An effort is now being started in one of the large pig-producing parts of Yorkshire to turn out ham and bacon wholesale, in fact on the American factory system.

Who but has read of the fame of York hams? Well, there is a little town about fifteen miles from York, on the banks of the Ouse, a great Potato and corn growing district, called Selby. The lord regnant in those parts is the Earl of Londesborough, a nobleman with vast estates, a nobleman always the first to forward any scheme for the betterment of his numerous tenantry and his hundreds of employés. The pigs are there of a fine type; the food is there in unlimited quantities, the energy and the skill are there, and the work only needed a little start and a little encouragement. Already Selby and the immediate neighbourhood annually breed 27,000 pigs, the greater portion of which are sent South, and there must be something in the quality, or the demand would not be so great.

If this be the result of individual effort we are not oversanguine when we prophesy far greater achievements for the newly formed bacon factory. Denmark has had the pull of us some time in regard to factory or co-operative butter. The farmers were not slow to find out that uniformity could not be attained when each farmer made up his few lbs. of butter at home. They grasped the situation, and took the world by storm with their tons of prime butter, all of which was absolutely of one quality and colour. Just glance for a moment at a few facts respecting Danish bacon factories and the impetus they have given Danish trade.

Up to 1887 the shipments of bacon from that country never exceeded 15,000 tons. In that year the exports were doubled, and the following year nearly trebled. Bacon factories are at the bottom of this wonderful advance. Denmark has not the population of Yorkshire, and yet she has no less than sixty factories, one-third of which are co-operative. Roughly estimated the value of the bacon industry in Denmark cannot fall far short of 2½ millions sterling; that and the butter trade fairly "make" Denmark.

From our personal knowledge of Selby and the adjacent district, from our knowledge of the men who are the promoters of the scheme, we have little doubt but that the bacon factory of Selby will, when fairly in working order, come to be numbered amongst the great commercial enterprises of Yorkshire, a credit to its originators and a profit to its proprietors.

WORK ON THE HOME FARM.

Thunderstorms have quickly broken up the short spell of fine weather inaugurated by the Queen's Jubilee, and farmers with a large breadth of grass in swathe are anxiously studying the weather forecasts. With the commencement of July we invariably have more or less of electrical disturbance, and it behoves every haymaker now to make hay while the sun shines, for storms must be expected.

With thundery weather we have a considerable increase of temperature—a very welcome change, for both Swedes and Turnips were coming very slowly to the hoe; and as rapid growth in the early stages is very essential to success in Turnip growing, humid warmth was just the thing we were longing for. Wheats are in full flower, in some cases getting past that stage. We are hoping that the straw, which at present is rather short, may lengthen out considerably. Barley, on the other hand, is quite high enough, and may become badly laid by heavy rains.

We are about drilling a piece of Rape for autumn feed; we are in doubt which is the better system, drilling in rows or broadcasting. In the present case the land is not quite clean, and can hardly be made so without completely working it as a summer fallow, so we are adopting the drilling plan, as with rows 20 inches apart we can keep the horse hoe at work between the rows until the plants begin to cover in. Then, again, less seed is required, for 3 lbs. per acre is enough in rows, whereas broadcast 7 or 8 lbs. would be none too little.

It might not appear likely that much benefit would accrue from striking out or thinning the plants of Rape in the rows, but we have proved the value of such thinning—the plants grow more rapidly, with a much sourer and stronger leaf, whilst if a portion of the crop be thinned out and a portion left thick, the sheep when folded will eat off the thinned portion level with the ground, leaving no stalk, whilst the unthinned portion will be a mass of hard fibry stalks, that no animal will consume.

With haymaking to complete, the great bulk of the root crops to hoe and clean, and the stock of winter coals to get in, there will be no lack of work before harvest, which may be here sooner than we expect if we are favoured with any great heat during the next week or two.

THE "LIVE STOCK JOURNAL."—The summer number of this excellent periodical contains two coloured plates, and two plates from wood engravings. There are also a large number of engravings throughout the text, every page in fact being illustrated with portraits of live stock. The articles are numerous and well written. The progress of stock-breeding during the Queen's reign receives due attention.

REMARKS.

27th.—Overcast early; heavy rain from 10.15 A.M. to 11.30 A.M., and some sunshine in afternoon.
28th.—Overcast till 10 A.M.; frequently sunny after; overcast evening; and rain from 8 30 to 10 P.M., followed by lightning
29th.—Dull and damp early; cloudy morning; sunny afternoon.
30th.—Bright sun all morning; cloud from 0.30 P.M.
1st.—Bright sunshine almost throughout.
2nd.—Overcast all day.
3rd.—Alternate cloud and sunshine all day.
Another fine seasonable week; nights very warm.—G. J. SYMONS.

Journal of Horticulture.

THURSDAY, JULY 15, 1897.

THE JOURNAL OF HORTICULTURE *can be obtained from the Office*, 171, *Fleet Street, London, post free for a Quarter*, 3*s.* 9*d. Editorial communications must be addressed to* 8, *Rose Hill Road, Wandsworth.*

STRAWBERRY CULTURE.

THERE can be no doubt that during the last ten years sound knowledge on Strawberry culture has been very widely circulated. This is clearly shown by the good supplies of fine fruit to be met with in the markets of our great towns. To writers in the horticultural press, as well as to commercial competition, this improving state of affairs is, I think, due. The former urged the necessity of supplying a long felt want, and showed the way to do it. This induced market growers to take up the matter with spirit, then competition amongst themselves speedily brought about improved results. There is, however, still room for further advance, as towns of moderate size are by no means overstocked with good Strawberries in a perfectly fresh condition, and many amateurs who like to produce their own fruit have not yet succeeded in doing so to their satisfaction. I trust, therefore, that the notes I am about to pen on this important subject will be productive of good in many ways.

Fortunately this delicious fruit is by no means fastidious in regard to soil, as stiff, light, peaty, or even naturally poor soil, will, with suitable culture, produce good crops, but the ideal soil for the purpose is the moderately stiff yellow or brown loam, which gardeners and farmers rightly set high value upon. No one should, however, be discouraged if they have to deal with a light and poor soil, as deep digging and mulching with manure will enable the poorest soils to produce good crops of Strawberries. But in such cases fresh plantations should be made each year, whereas when planted in good loamy soils the plants may be profitably allowed to occupy the same ground for three years.

In preparing light soils for the reception of Strawberry plants, trenching to a depth of 2 feet should be resorted to. As the work proceeds, plenty of half-decayed manure must be incorporated with the soil, more especially in the lower strata. The subsoil should not be brought to the surface except in very small quantities, as

the surface of land which has been for years exposed to atmospheric influences, as well as to continual digging and stirring, is comparatively rich and sweet, and therefore more capable of inducing active root action in plants and finer crops of fruit than is the soil beneath it, for however deep and naturally fertile soil may be, the penetration of air is necessary to bring out its full capabilities. It is, therefore, not difficult to see the immense advantage of periodical trenching, which sweetens and enriches soils to a great depth, and gives to crops a double sized larder to draw their supplies of food from. One reason why very light soils are less fertile than heavy ones is that they do not possess the power to retain, for any length of time, the food stored in them, as water goes through them too rapidly, carrying with it the elements of fertility far away from the reach of roots. A surface dressing of clay applied to land of this description is of great advantage by gradually making it more "holding" in texture. When this is applied in winter, it should be spread roughly upon the surface, and allowed to lie for some weeks till the action of frost has reduced it to small particles. If applied during the summer, it should be dried and crushed. Manure from cowsheds is preferable to that obtained from other sources for light soils, as it is not only a powerful fertiliser, but is close in texture, and therefore tends to make light soils more retentive of moisture.

In dealing with very heavy land, we have in many respects to reverse our plan of action, so as to render the soil more open and workable, and prevent it from becoming hard and brick-like under the influence of sun, or soft and sodden during and long after heavy rains. The first step toward improving these very heavy soils is to drain them; then trenching must follow, working in freely during the operation burnt refuse, old mortar rubble, coal ashes, or any materials of a like description, which will serve to keep the soil open and sweet. The most suitable manure to use in such cases is fresh strawy material, just as it comes from the stable. Land well prepared in this way will, especially in dry seasons, bear grand crops of Strawberries, if othor details of culture are well carried out.

An old plan of growing Strawberries on heavy land was to plant them on raised beds. Drainage was in this way secured; but in dry seasons the soil caked and cracked badly, while watering could not be satisfactorily done. It proved to be an expensive method of making beds, and all operations were performed at a disadvantage. The principle to work on in the improvement of heavy soils is to make them open and friable; the raised bed system does not do this, hence its failure, and therefore almost total abandonment by our foremost cultivators.

Raising Plants.

It is important that plants be established early, so as to be ready for planting in the prepared ground by the first or second week in August. Those who raise large numbers of plants yearly make a practice of having a row or plot of young plants in a warm position, which are grown principally for supplying early runners. Those who watch Strawberry plants closely will observe that young plantlets usually form just before the fruit begins to change. To layer these in the usual way would greatly interfere with the gathering of the fruits, and yet it is from such early runners that the best plants are obtained. It is, therefore, obviously a good plan to grow plants entirely for supplying early runners. Where, however, this is not done, layering should commence directly fruit picking is completed. Only the best and strongest runners ought to be layered, the others being cut away. Some cultivators peg the young plantlets into small pots filled with soil, others use turves cut into pieces about 3 inches square, and many successful growers simply loosen the soil round the old plants and peg the young ones into the loosened surface. Either plan answers well provided regular waterings are given during the absence of rain until the plants are well established. As the work of layering proceeds a sharp look-out must be kept for barren plants. These must on no account be propagated from, although they usually produce extra good plantlets, and seem to invite attention on account of their exuberant growth. Those who have only a limited number of plants to raise their stock from, and these perhaps not being in good condition, should purchase young plants from a reliable Strawberry grower or nurseryman. Such can be obtained at a wonderfully cheap rate, and an occasional change of stock is a distinct advantage.—Pomona.

(To be continued.)

HONOURS IN HORTICULTURE.

Under this heading last week we made reference to the "Victoria Medal of Honour," which has been founded by the Royal Horticultural Society to commemorate the Queen's long reign, and we published a list of (as we supposed) the first recipients of the honour. We much regret that the list was not accurate. Some names were included which ought not to have appeared in accordance with the final decision of the Council, while others were left out which ought to have been there.

In response to our application a list was obligingly supplied to us shortly before going to press, but in his haste to supply it to us in time the Secretary made use of an old printed list of many names, some of which were erased, and others were added in writing, and unfortunately the explanation as to which of the erasures and additions were to stand and which to be ignored was misunderstood. It was simply a list sent most kindly, but in a hurry, and equally printed in a hurry, time not permitting a proof being submitted to the Secretary, the result admirably illustrating the truth of the maxim—"the more haste the less speed." Our list contained the names of several members of the Council, who, in our opinion, were fully entitled to the distinction, and who might well have received the honour but for the self-sacrifice they have preferred to make. The sentiment is admirable, and though we are pleased to see the additions, we cannot but regret that gentlemen who have rendered signal services to horticulture in various ways, and over many years, should have deemed themselves ineligible for the distinction simply because they happen to have been elected to a position of honour—a seat at the Council table of the Royal Horticultural Society.

In one sense, therefore, we are glad that the mistake occurred, as it has given us an opportunity of expressing the estimation in which we, in common with all the gardening world, hold those gentlemen whose names do not now appear in the final list

But since we have said thus much we feel entitled to say a little more—namely, that as some of our remarks may, at least in a negative way, be regarded as a reflection on those recipients of the honour whose names should have appeared in our list last week, but did not, we have the pleasure of stating that with two exceptions the names of all the gentlemen omitted were included in a list that we drew up for the purpose of comparison with the final selection.

We are requested by the Secretary to say that the erroneous list accidentally published last week was one of numerous lists submitted to the Council some time ago, but was never at any time adopted or approved by them. It was only carefully considered, as were all the others submitted.

As we accidentally published an incorrect list of what one gentleman calls the "Academy," it is incumbent that we publish a correct one as follows:—

The following are the names of the first sixty recipients of the Victoria Medal:—

Baker, John Gilbert, F.R.S., F.L.S., Royal Herbarium, Kew.
Balfour, Prof. Isaac Bayley, M.A., Sc.D., M.D., C.M., F.R.S., F.L.S., &c., Royal Botanic Gardens, Edinburgh.
Barr, Peter, King Street, Covent Garden.
Barron, Archibald F., Sutton Court Road, Chiswick.
Beale, Edward John, F.L.S., Stoneydeep House, Teddington Grove.
Boxall, W., 186, Brook Road, Upper Clapton, N.E.
Bunyard, George, Royal Nurseries, Maidstone.
Bull, William, F.L.S., King's Road, Chelsea.
Burbidge, Frederick William, M.A., F.L.S., Trinity College Bot. Gardens, Dublin.
Crump, William, Madresfield Court Gardens, Malvern.
Dean, Richard, Ranelagh Road, Ealing.
Dickson, George, Chester.
D'Ombrain, Rev. H. H., Westwell Vicarage, Ashford, Kent.
Dunn, Malcolm, Palace Gardens, Dalkeith.
Druery, Charles T., F.L.S., 11, Shaw Road, Acton, W.
Ellacombe, Rev. Canon, Bitton Vicarage, Bristol.
Elwes, H. J., F.L.S., Colesborne, Andoversford, Glos.
Foster, Prof. Michael, M.A., M.D., LL.D., F.R.S.
Fraser, John, South Woodford.

Gordon, George, Endsleigh, Priory Park, Kew.
Heal, John, 10, Musgrove Crescent, Fulham, S.W.
Henslow, Rev. George, M.A., F.L.S., &c., Drayton House, Ealing.
Herbst, H., Stanmore, Kew Road, Richmond.
Hole, The Very Rev. S. Reynolds, Dean of Rochester.
Hooker, Sir Joseph Dalton, M.D., K.C.S.I., G.C.S.I., F.R.S., Sunningdale, Berks.
Horner, Rev. F. D., Kirkby-in-Lonsdale.
Hudson, James, Gunnersbury House Gardens, Acton, W.
Jekyll, Miss Gertrude, Munstead Wood, Godalming.
Kay, Peter, Claigmar, Finchley, N.
Laing, John, Forest Hill, S.E.
Maries, Charles, F.L.S., The Residency, Gwalior, Morar, India.
McIndoe, James, Hutton Hall Gardens, Guisborough.
Milner, Henry Ernest, F.L.S., Dulwich Wood, Norwood, S.E.
Molyneux, Edwin, Swanmore Park Gardens, Bishop's Waltham.
Monro, George, Covent Garden.
Moore, Fred. W., A.L.S., Royal Botanic Gardens, Glasnevin.
Morris, Dr. Daniel, M.A., C.M.G., D.Sc., F.L.S., Royal Gardens, Kew.
Nicholson, George, A.L.S., Royal Gardens, Kew.
O'Brien, James, Harrow-on-the-Hill.
Paul, George, The Old Nurseries, Cheshunt.
Paul, William, F.L.S., Waltham Cross.
Rivers, T. Francis, Sawbridgeworth.
Rothschild, Hon. Walter, 148, Piccadilly, W.
Sander, Frederick, St Albans.
Schröder, Baron, The Dell, Staines.
Seden, John, Middle Green, Langley.
Sherwood, N. N., Dunedin, Streatham Hill, S.W.
Smith, James, Mentmore Gardens, Leighton Buzzard.
Smith, Martin R., Hayes Common, Beckenham.
Speed, W., Penrhyn Castle Gardens.
Sutton, Arthur W., F.L.S., Reading.
Thomas, Owen, Royal Gardens, Windsor.
Thomson, David, late of Drumlanrig, N.B.
Thompson, William, Ipswich.
Turner, H., Slough.
Willmott, Miss Ellen, Warley Place, Great Warley, Essex.
Wilson, George F., F.R.S., F.L.S., &c., Heatherbank, Weybridge Heath.
Wolley-Dod, Rev. C., Edge Hall, Malpas, Cheshire.
Wright, John, Rose Hill Road, Wandsworth.
Wythes, George, Syon House Gardens, Brentford.

JUBILEE REFLECTIONS.

Founders of Our Faith.

(*Concluded from page* 2.)

There is no more honoured name in the annals of scientific horticulture than that of Sir Joseph Banks, who, like the illustrious Swede, Linnæus, early in life became the devotee of our imperious mistress—Nature. Like, and unlike, for whilst the latter in early life wrestled with poverty, young Banks was born with the proverbial silver spoon with which to sip the sweets presented by affluent circumstances. In 1743 the subject of our brief sketch first saw the light, and the death of his father whilst he, the eldest son, was yet a youth brought changes which resulted in the family estate of Revesby in Lincolnshire being given up, the widowed mother with her family removing to Chelsea. No happier choice of a residence could have been made to foster the love of that particular study so early displayed by this eminent man; Chelsea and the neighbourhood, it need scarcely be remarked, affording great facilities to the young student, being then famous for its scientific gardens, including that of Sir Hans Sloane.

Having here introduced the name of this distinguished man—Sir Hans Sloane—who died in 1752, at the time when young Banks had only attained his ninth year, we may, by reason of the undoubted influence his life and labours exercised over him, and of which his—Sir Joseph's—life was in many ways a replica, digress with a few details. In the highest rank as a physician and naturalist, Sir Hans, as a boy, showed a remarkable propensity for the study of those subjects which brought to him honour and length of days. Born in 1660, he was created a Baronet by George I. in 1716, and in 1727 succeeded Sir Isaac Newton as President of the Royal Society, resigning this post in his eightieth year. From his marvellous collections, which were at his death accepted by Parliament for the nation conditionally upon his family receiving the sum of £20,000, which had, indeed, cost him some £50,000 in forming, originates the British Museum. The whole career of Sir Hans Sloane marks him a man of high moral principle, and his rigid adherence to a temperate life which overcame a constitutional delicacy evidenced in his youth also preserved a noble intellect clear and bright to the end, which came in his ninety-second year.

How peculiarly fascinating the study of Nature must have been to the young gentleman, to whom we now return, it is easier to conceive by observing that neither fashion nor fortune, he being possessed of ample means, which, eventually, were chiefly devoted to the ruling passion of his life, could lure him from his early love. On coming of age a voyage was made to the then little known Newfoundland and Labrador coasts, and a valuable collection of plants, insects, and other natural productions was made and brought home, this being the first practical work of our young enthusiast, who was soon to engage in more extended research.

There is, I fear, some little danger of the rising generation taking rather a commonplace view of the travels of our great pioneer naturalists, viewing them in the strong light the latter days of our good Queen's reign now shed upon distant scenes. It would not, I think, be wasted time if our young gardeners would follow intently the tracks of these travellers; those, for instance, of the great circumnavigator, Captain Cook, upon his wonderful journeys. I, at least, found "Cook's Voyages" intensely interesting at that period of my life. Such would, moreover, convey a clearer idea of that dauntless character, which neither dangers nor difficulties, now all but disappeared, could dissipate. We may now couple the name of our young naturalist with that of this famed explorer, who was sent out to the Pacific to observe the transit of Venus, and make a voyage of general discovery. Mr. Banks not only accompanied him on this, a three-years voyage, but we find him sparing neither pains nor expense to make the self-imposed mission a complete success. To this end he engaged skilled draughtsmen to aid his own efforts, and secured the services of Dr. Solander, a pupil of Linnæus, to the great advantage of this phase of the enterprise.

At this period may be noted a friendly rivalry among the nations of Europe to further the cause of science, similar expeditions being despatched contemporaneously by the Empress Catherine of Russia and King Louis of France. Banks brought home a splendid collection of specimens, including a number from Otaheite, where, eventually, the intrepid seaman, Cook, laid down his life in the great cause, also from New Zealand and Australia. After this voyage, in 1772, Mr. Banks sailed at his own expense to Iceland, accompanied by Solander, Dr. Lind, and Von Troil, where two months were spent among the volcanoes. In 1777 Mr. Banks was elected President of the Royal Society, holding that position for over forty years. In 1781 a Baronetcy was conferred upon him, and further honours rewarded his assiduous labours by his being invested with the Order of the Bath in 1795, two years after being sworn in as a member of His Majesty's Privy Council.

Sir Joseph took a leading part in the management of the Royal Gardens at Kew, and promoted the interests of the Horticultural Society, founded in 1804. In his private life our great countryman is conspicuous by a highmindedness which sunk all petty considerations and jealousies, whose stings his eminent services did not exempt him from being the butt of during his active labours to advance the object of his life, independent of party feeling at home or national contention abroad. He finally gained the unqualified admiration and recognition of his learned contemporaries of all countries and creeds.

Indelibly engraved upon the roll of honour connected with our subject are various illustrious names—men who have here and there taken up the tangled web to patiently unravel it for our benefit. Only a few can be included here. Amongst these we may note Auguste Pyramus de Candolle, who, born at Geneva in 1788, was early inspired with the love of botanical research. The later part of his life was devoted to an attempt to simplify the classification of plants, which work, continued by his son, brings us down to modern times. Prior to this Antoine Laurent de Jussieu, born in 1748, was engaged upon similar work, and the combined efforts of these savants have given great and lasting results. So many of these names emphasise what has been previously mentioned—viz., that intimate relationship of the study of medicine with that of plants. Another example of this is furnished by the learned Sprengel, a leading physician and botanist of the last and present century. Previous to his death in 1833, upwards of seventy learned societies and academies had sent him their honorary diplomas, and several ruling monarchs conferred upon him orders of distinction. This not only shows the importance with which the work we must be more or less interested in was regarded, but speaks volumes for those who delighted to honour men who from the very nature of their work were probably the last to seek it.

There are no young thinkers and readers of to-day who can fail to be acquainted in a measure with the lives and labours of men of our own times, but they—we all do, perhaps—lightly estimate the riches of literature spread around us in such profusion. We take such things as a matter of course, although they are, we may admit, a consequence of progress under our good Queen. In our Jubilee reflections (horticultural reflections) it must be a matter of pride and of pleasure to think and to know that, as directly concerning us, all is not fleeting. Flower shows are fleeting, we do not disparage their educational value in saying so. Vast indeed is

the difference between our specimens and those illustrating the pages of old Gerarde's "Herbal," published 300 years ago, but greater still is the difference in that quaint volume and the modern work, which under the modest title of "The Flower Grower's Guide," comes so opportunely to leave its impress as a lasting record of what has been done—to show all practical gardeners what they can do—in this the sixtieth year of the Queen-Empress's reign. —INVICTA.

COMMEMORATIVE TREE PLANTING IN 1897.

THIS subject, in this memorable year, has worthily engaged the attention of the many more or less interested in it, but whether the work already carried out is sufficiently pronounced to warrant the assumption that the far-reaching object may reasonably be expected to obtain is a matter for conjecture. There is, in fact, a combination of circumstances militating directly or indirectly against it, tending to the conclusion, which many upon reflection may arrive at, that the outlook is not one of unqualified satisfaction; whereas, *per contra*, there are no reasons why it should not be made one of the most pleasing features of the present, that is so far as the contemplation of future effect is concerned. Upon this year's work is, of course, hinged the door of prospective possibilities. That this particular planting should—must—take place in this particular year goes without saying, and that we have yet before us the most suitable time in late autumnal or early winter planting to accomplish the most important part of it may be admitted.

Much has probably been done even with our noble deciduous trees by special preparation of them in some instances to undergo the ordeal of summer planting, as well as spring planting in the natural way; yet in the latter case, from various reasons, it may have, as in some cases I know it has, been too long deferred to expect the best results, and the former has been far too desultory to fully attain the end in view when viewing it under its most comprehensive aspect. Therefore much that has been done was probably done at an unsuitable time, and a great deal of that with, possibly, more or less unsuitable subjects—trees. If we could reasonably hope that the coming planting season would in this direction be met with the same zeal practically demonstrated in other ways, any present comment upon the matter would be needless, but there is more than a slight danger of a too rapid evaporation, not of our loyalty, but of that jubilance which finds with it a ready outlet of ways and means to the end—commemoration.

In the normal course of things thousands of suitable trees will doubtless this year be planted in permanent positions, many of which will eventually become interesting objects so far as tree life is concerned; but that does not affect the question. Keeping our special object in view, it is obvious that some kind of identification, which must be both simple and reliable for the benefit of generations to come, is both desirable and necessary, and those planters who yet intend to take advantage of the best opportunities, which are yet ahead, will, by bearing this in mind, be governed more by reason than led by inclination to plant new or untried varieties, which planting must be more or less experimental, and for which properly our subject has no margin. Considering first the methods which best suggest themselves to the end of permanent identification, we need only consider that phase of it which directly concerns the general public, taking it for granted that in private places, demesnes, or what not, such matters will be well considered.

Hypothetically considering that every parish in the kingdom which has not done anything in this direction, or as much as might have been done, intends doing the right thing at the right time—the coming planting season, and further supposing that the good, yet inexpensive, work will be judiciously done, the question of future identification should present but little or no difficulty. One parish may, possibly, devote a suitably enclosed space for its grove of a dozen "Victoria" Oaks, and grave on stone the why and wherefore of its being; whilst to others various methods may commend themselves which do not admit of labelling *in perpetuo*. In the latter cases, which would, probably, embrace the majority, correct data inscribed upon the parish records might be expected, so far as one can see, to fulfil all requirements. In this case particulars might include the correct measurement of distances from the nearest permanent landmarks available for the purpose.

Relative to suitable varieties for memorial planting amongst the large number now available, or supposed to be, for the purpose, a little serious consideration of the matter will show that all desire for novelty should give place to the trusty and tried over long periods, as proved in the annals of arboricultural history. Moreover, that local conditions of soil, situation, and general suitability will be duly recognised. Probably here the simplest plan would prove the safest, and those giants of the tribe who stand as silent witnesses of long endurance under the vicissitudes of our climate are the best kinds for the purpose. With these it is but reasonable to expect that history will repeat itself.

Turning up the pages of an historical work of this kind—viz., "Sylva Britannica," a handsome old folio volume of plates drawn from nature of trees remarkable for their antiquity, magnitude, or beauty, also etched and published by Jacob George Strutt in 1826, data are furnished which should be both of interest and service to us now. Of the forty plates and descriptive letterpress relative to England (eight plates of remarkable Scottish trees conclude this work), we find the author visiting at least fifteen different counties for his purpose, without a doubt drawn to each particular spot by the name and fame of some particular tree. Predilection may in some measure account, perhaps, for Strutt's honourable mention of so many famous Oaks, but judging by his enthusiastic description of other species illustrated, that alone cannot be answerable for the pre-eminence given to them, exactly half of the forty fine plates being those of famous Oaks. The remaining twenty consist of six Elms, three Chestnuts, two Limes, two Yews, and one each of Maple, Sycamore, Poplar, Willow, Ash, Beech, and Cedar.

Where we require on the larger scale grandeur and endurance we may from the data adduced, coupled with personal knowledge of the kingly tree and various associations linking it with English history, acknowledge its supremacy for the object in question. Dwarfed as is the English Yew by comparison with the Oak, it holds, we may allow, the same prominent position on the smaller scale, and its adaptability to various positions from which the former might be precluded no less commends it to our notice. For longevity the Yew, as far as I am aware, takes the highest rank. Details of other suitable species need not detain, for in this case variety will, doubtless, charm future generations if a judicious selection guides our efforts in this phase of commemoration. These lines are penned by a lover of our noble indigenous trees in the hope that ere this year of Jubilee has fled that in every village and in every hamlet over the length and breadth of Old England something will be done in this direction, and well done, and that means will also be taken to attest the fact for the benefit of posterity. May I also suggest that brief particulars might be forwarded to our Editor, that the *Journal of Horticulture* could also tell the tale to tree lovers yet to come?—SYLVA.

MARGUERITE CARNATIONS.

SINCE the introduction of Marguerite Carnations it is possible to sow seed, raise good plants, and obtain useful sweet-scented flowers for cutting in autumn. A period of seven months' cultivation suffices to obtain the first results. It is true the plants are not so floriferous the first year as the second, but this is simply owing to their being less in size. However, the blooms, if good, whether produced in quantity or not, prove very welcome, either as buttonhole flowers or for adding to a miscellaneous collection. An additional advantage gained in their flowering the first season is that of ascertaining the quality of the blooms. Few if any strains of seed furnish plants having all double and no single-flowered plants. The latter, therefore, being discovered when the seedlings bloom may promptly be discarded and the best retained.

A packet of seeds of a good strain, either of mixed colours or all white, may be sown at the end of February or early in March. White varieties are usually kept separate, so if white Marguerites are in demand include a special sowing, which may be cultivated separately.

Employ well drained pots or pans and a light open compost. The seed will germinate in a temperature of 55°. Keep the seedlings from their first appearance near the light so as to avoid their becoming drawn, watering lightly but sufficiently. As soon as the young seedlings attain strength and soon would be crowded it will be best to separate them, pricking them out 2 inches apart in boxes drained and filled with a similar compost. They may remain there for some time, say until the end of May, when they can be finally planted. Light is very essential to their steady progress, and a cooler position with a moderate amount of air given, but freely on favourable occasions, favours development while in the boxes. The waterings must be applied lightly during the first few weeks, so that the plants can easily form rootlets, which they will do more freely in a healthfully moist medium rather than a wet one. No place is more suitable than a cold frame. The lights may be removed and the plants fully exposed prior to planting.

Though the Carnation prefers a fairly moist and rich soil, yet it will succeed in a somewhat dry position, such as a sloping bank, when once the roots have taken deep hold. The plants winter well in a position of that kind, not being subject to damp. A flat

and open position, well drained in winter, must be considered the best position, because there is adequate provision for their demands with regard to moisture and food in the soil at a period when both are required to well support the advancing flower stems.

Encourage the first blooms to be produced as early as possible so that the quality may be noted. The double flowering varieties only are worth cultivating, and as these plants are quite as free in the production of blooms as inferior varieties, it is simply waste of space to retain the latter. The flowers open successionally and last a fair time in good condition. Seed sown at the period indicated produce plants which will, with fairly good culture, commence to bloom in August, and continue until late in autumn.

Plants well furnished with buds are frequently found serviceable in winter if carefully lifted and potted. In a genial greenhouse temperature with the plants close to the light on a shelf many useful blooms may be cut in winter or early spring. Replanted outdoors again in spring they would bloom freely at the usual time, supporting the growth as required with adequate supplies of water. Where it is found difficult to winter Marguerite Carnations outdoors some seedlings should be grown on in pots or planted in a frame where the needful protection from frost and damp can be readily afforded.

The practice of layering in the same manner as choice Carnations are treated is really not necessary owing to their reproduction from seed being so quickly effected. This renders it quite easy to maintain the stock of plants. When one batch of plants commences to decay in vigour another may readily take its place. —E. D. S.

CALOPOGON PULCHELLUS.

Considering the comparative scarcity of greenhouse and hardy Orchids it is a matter for great surprise that Calopogon pulchellus (fig. 8) should so seldom be seen. As it was brought into this country from North America as long as 125 years ago it might have been expected that it would have received wide attention, but as a matter of fact it is little known. When well grown it is about 1½ foot high, bearing three, four or five flowers on a stem, and its attractiveness is unquestioned. The individual flowers are about an inch across, and though not large they are eminently pleasing in appearance and bright in colour. Paxton describes the blooms as purple, but they are in reality bright rosy mauve and borne on slender stems. Though usually grown in the greenhouse it has been found perfectly hardy in a cool shady spot in moist soil.

HARMFUL AND HARMLESS GARDEN MOTHS—4.

The renowned Linnæus grouped with the large or middle-sized hawk moths, I have mentioned already as adorners of gardens, some insects much smaller, whose principal resemblance to their big brethren lay in the antennæ, which are thickened towards the ends, and slightly feathered. By this arrangement they were placed also upon the list of twilight fliers, but really these brisk moths are, with few exceptions, lovers of sunshine, delighting to hover round the flowers, or skip from leaf to leaf. Now we call them the clear-wings, because these are transparent, and many of the species, in fact, closely resemble flies, or slim insects of the bee tribe. Doubtless, many a gardener passes them and does not think they are moths; possibly the resemblance also deceives insect-eating birds and predatory insects, though it may not matter much to these whether moth or fly has been secured. The caterpillars of clear-wings, unlike those of the hawk moths, which mostly feed in full view, pass their lives under concealment, and if brought into daylight by the pruning or cutting of their food-plants, seem considerably embarrassed. To anyone ignorant of entomology their appearance would suggest the larva of a fly or beetle rather than that of a moth.

We cannot take a better example of this family than the Currant clear-wing (Sesia tipuliformis), which is common at midsummer and for a short time after, occurring about gardens, also in orchards. It is a pretty sight on a fine day to see parties of this moth, their gauzy wings radiant with sunlight, and the dark tuft expanded at the end of the belted body; but we remember the species is one of our garden enemies, and to capture some of them is allowable. However, they can seldom be taken by the fingers, nor is it easy to catch them with a hand net. The caterpillars, pale in colour, and muscular though small, live in the branches and twigs of the Currant, evidently preferring the black variety, but they occur also on other kinds. Sometimes it may happen that bushes infested bear plentifully for awhile, yet in time we find that those boughs where the pith has been mined die off, and I have noticed that when several caterpillars have pierced the main stem the bush may be killed. From observation, I believe they pass two winters in the caterpillar state, that is to say from the eggs laid this summer moths will not be produced till 1899. Probably they do not feed during very cold weather, and they seem to choose for their winter life such positions in the bushes as are most protected. Now, this lengthy period of caterpillar existence is of some moment with this and with the larvæ of some other moths, of some beetles too.

Let us look at its bearing upon the injuries such a species may do, if it is a destructive one. We perceive that there are two broods of the caterpillar or larva always living, and capable of doing mischief. But when a species runs through its course during

Fig. 8.—Calopogon pulchellus.

a year, for several months thereof no harm is done while it is in the perfect state, or is a chrysalis or egg. Many of these caterpillars may be got rid of by judicious pruning.

Next in importance as a garden insect is the pretty red-belted clear-wing (S. myopæformis), so named from its resemblance to a sort of fly. It is certainly not "myopic" or near-sighted, but a lively insect, and occasionally flies high. Its period of emergence is about midsummer, though it has been taken in May and up to the end of July. Some years ago the insect swarmed amongst the Surrey orchards to the south of the Metropolis. Another name for it is the Apple clear-wing, but it is quite as frequent on the Pear, where the trunks or larger branches are its usual abode. The caterpillars living on Apple select generally the slender wood. Productiveness may not be interfered with at first, but after a time the branches attacked are killed and the whole tree will suffer should there be hundreds of caterpillars in it, which is now and then the case. Their presence is often discernible by moist spots on bark or by the appearance of small particles extruded through a crack at the nodes. A correspondent of this Journal sent us, in 1879,

specimens of Apricots from a wall at St. Fagans which had been seriously damaged by the caterpillars of the above species; there may have been similar instances elsewhere, though not reported.

There are other clear-wings, some tolerably abundant, several rare and local, which join the company of our garden insects in the summer months, attracted by flowers, yet which have bred elsewhere in plantations or shrubberies, perhaps on waste ground. A few seldom travel far from the home of the caterpillar; the yellow-legged species, for example, which occurs in Hyde Park, probably in other London parks and elsewhere, is reluctant to go many yards beyond the Oaks and Elms after it has emerged. But the red-tipped clear-wing (S. formicæformis), sometimes abundant enough within Osier twigs to cause damage, likes to take an excursion on the wing, and when an entomologist is searching for this moth amongst the Osiers and Willows he may be disappointed—the insects he seeks are taking the air elsewhere, to return home at dusk. Gardens near parks and woods may invite the Birch-eater, S. culciformis, another species that is red-belted, and thrives while caterpillar in old stumps of that tree. Much larger than these, and really not unlike a hornet, is the hornet or Poplar clear-wing, a midsummer insect that has scared some people. But the antennæ are longer, the wings rather more ample, and the banded body downy, not hard to the touch. Nor does it produce the warning sound which gives notice of a hornet's proximity. The caterpillar lives two years in the solid wood of Poplars or Aspens, then quits it to make a cocoon outside of silk and chips, usually placed near the foot of the tree.

Pass we now to another moth of larger size, which about this season we may happen to see in flight after dark, or resting by day upon a tree. Though its wings are not clear they are partly transparent, especially in the females, which are larger than their male companions, and remain out till the middle of August, the egg-laying operation taking some time. This is the leopard, also named Zeuzera Æsculi, but it has no marked partiality for the species of Æsculus, being rather a general feeder as a caterpillar. It is certainly one of our beautiful moths, the snowy white of the wings and thorax being thickly dotted with black or bluish-black spots, the abdomen is also banded. Indeed, the first observed specimens of this moth were regarded as so curious during last century that they were sold at half a guinea each. Probably the insects would be much commoner if sundry birds did not seek it, frequently seizing one before the wings are expanded, and it is chased by bats. The caterpillars commence life by feeding on the bark of some tree, but soon pierce into the wood, and construct galleries along stem or branches. They work on for nearly two years before they assume the chrysalis state. Before changing each caterpillar (which is spotted similarly to the moth, having a horny plate behind the head) makes a cocoon of wood dust close to the surface, so that it can easily emerge.

Long is the list of ornamental trees it attacks; amongst the trees of our orchards, the Apple, Pear, and Plum are selected. If, for awhile, the fruit-bearing power seems unaffected, by degrees the branches that are ruined show signs of the attacks, or the tree itself becomes feeble. Indications of the presence of these caterpillars are discernible outside the burrows, and they have been killed by running flexible wire into their holes; also by the injection, with a syringe, of liquid ammonia and other poisonous fluids, perhaps at some risk of mischief to the infected tree. Blowing the fumes of sulphur or tobacco into the openings has also been suggested. The still larger and sombre-hued goat moth (Zyleutes Cossus) occasionally careers slowly over gardens in July, having bred, it is likely, in some Elm or Willow near, for these trees are the special favourites of the caterpillar, which is presumed to exist three or even four years in that state, doing damage to many trees. It has been said the moth has been captured at sugar spread as a bait upon trees or palings.—Entomologist.

SCHOOL GARDENS.

I apologise to "T. D. S." for not having previously answered his request for further information, given under the above heading at page 10. It was needful to obtain a copy of the Education Department's code of regulations for the year to get the required knowledge. As previously intimated the subject of "Cottage Gardening" is a special and exceptional one, and is of course chiefly applicable for use in rural schools. These, because generally so poor, hardly care to take a subject that, whilst of the highest practical value to the scholars, is such a poor grant earner, so much of our educational work—to our shame be it said—being dependent not on its ultimate value to the children taught, but to the managers and teachers in a pecuniary sense now in a rural school.

But whilst grants may be earned in history, geography, and elementary science, purely academical subjects, cheaply—that is, at the cost of a few books—such very important technical or practical subjects as cottage gardening, dairy work, laundry work and cookery, cannot be taken without there being in the first place considerable outlay. Thus in cottage gardening the grant is but 2s. per head per annum if only twenty hours instruction be given, and but 4s. per head if forty hours be thus employed. Each class must also comprise not more than fourteen scholars, whilst it is obvious that a practical instructor could just as well teach twenty as fourteen. But the requirements of such practical instruction are ground for gardens, tools for the boys, manures, and seeds for cropping; also a tool shed, wheelbarrow, and water appliances. The provision of these things would require at the outset an outlay equivalent to all that a class would earn in two or three years. Then unless the school teacher be a capable gardener, a practical gardener teacher must be hired to instruct the lads for one or two hours per week.

Thus it is seen how very heavily the suggested subject is handicapped at the outset. It is very easy to understand also that inspectors of schools of the ordinary academic class would look askance on a subject of which they were entirely ignorant. I take it for granted if "T. D. S." would like to do something useful in this direction in Birkenhead he had better approach some of the School Board or voluntary managers first, and seek to induce them to take up cottage gardening as a special subject in their boys' schools. It is entirely for them to do as they please. It would not be a matter for surprise if on the threshold of his beneficent labour in the cause of real technical education in elementary schools he were met by the objection that the subject would earn little or no money.

Still, if land for the purpose could be freely placed at initial disposal, and contiguous to the schools, one difficulty would be overcome, so very much would then depend on finding sympathy, or otherwise. County Councils in their Technical Education Scheme have not to consider grants, and can, as is done in Surrey, start cottage gardening for lads who have left school in a liberal as well as in a practical way. Cottage gardening is found in the Year's Education Code, on page 26, article 101, section K.—A. D.

ROYAL HORTICULTURAL SOCIETY.

Drill Hall, July 13th.

The major portion of the exhibits at the Drill Hall on Tuesday were composed of hardy flowers. Messrs. Veitch's Gooseberries and Mr. Beckett's vegetables made a handsome display, but Orchids were far from numerous.

Fruit Committee.—Present: T. Francis Rivers, Esq. (in the chair); with Messrs. G. Bunyard, P. C. M. Veitch, J. Cheal, A. H. Pearson, A. Dean, G. H. Sage, G. Wythes, C. Herrin, and H. Balderson.

Messrs. T. Rivers & Son, Sawbridgeworth, Herts, exhibited a splendid collection of Cherries, comprising a score of distinct varieties. Almost all the varieties were represented by superb fruits, but Frogmore Bigarreau, Bigarreau Noir de Guben, Géant d'Hedelfinger, Monstreuse de Mezel, Bigarreau Napoleon, Turkey Black Heart, White Bigarreau, Early Rivers, Elton, and Empress Eugénie were certainly the handsomest (silver-gilt Knightian medal)

A collection of Lettuces was exhibited by Messrs. J. Carter & Co., High Holborn. Both Cos and Cabbage sorts were represented to the number of thirty-one. With so many it was difficult to decide which were the best, but All the Year Round, Perpignan, Continuity, New York, Grand Admiral, Victoria, and Tom Thumb amongst the Cabbage varieties, with Sugarloaf, Baldwin, Paris Green, and Dunnett's Giant White of the Cos, were some of the best. Ten varieties of Turnips were also shown by this firm, and included Early Milan, Early Munich, Extra Early French, Golden Rose, and others (silver Banksian medal).

Upwards of fifty dishes of Peas were sent by Messrs. W. W. Johnson and Son, Boston. Some of the varieties were shown considerably too early, the pods not being nearly full, while others were quite ready. A few of the best were Duke of York, Gradus, Boston Unrivalled, Witham Wonder, Telegraph, Sutton's Excelsior, Goliath, Telephone, Sutton's Forcing, and Empress of India (silver Banksian medal).

Mr. H. Eckford, Wem, Salop, staged Peas Diamond Jubilee, Wem Giant Marrow, Prior, Ideal, and Pioneer, all of which were handsome podded varieties. Messrs. R. Veitch & Son, Exeter, staged Veitch's Perfection and Goldfinder Peas and Exhibition Long-pod Beans.

Messrs. J. Veitch & Sons, Ltd., Chelsea, exhibited a box of Veitch's Perfection Strawberries; and Mr. W. Allan, gardener to Lord Suffield, Gunton Park, sent two boxes of Strawberry Lady Suffield.

The finest exhibit in this section was that arranged by Mr. E. Beckett, gardener to Lord Aldenham, Aldenham House, Elstree. Every single dish was good; some were perhaps better than others, but there was not one weak on the table. There were Potatoes Rivers' Royal Ashleaf and Sharpe's Victor; Cauliflowers Webb's Mammoth, Veitch's Autumn Giant, and Walcheren; Lettuces Sutton's Early Mammoth, Webb's New Wonderful, and Sutton's Superb White Cos; Carrots James' Intermediate, Early Gem, and Sutton's Intermediate; Peas Duke of Albany, Telegraph, and Carter's Early Morn; Beans Canadian Wonder, Ne Plus Ultra, Mammoth Broad, and Leviathan Broad; Turnip Sutton's Snowball; Vegetable Marrows Moore's Cream, Pen-y-byd, and Long White; Cabbage Carter's Model; Tomatoes Polegate and Sutton's Perfection; Cucumber Beckett's Victory; Onions White Leviathan and Red Italian; Globe Artichokes Green and Purple; Radish French Breakfast; Beet Sutton's Red Globe, and a dish of Mushrooms (gold medal).

Messrs. J. Veitch & Sons, Ltd., sent a collection of Gooseberries, comprising standards, bushes, cup-shaped and gridiron-shaped trees. They were splendid examples of training, and were carrying large

numbers of fruits. The varieties were Railway, Gipsy Queen, Hue and Cry, Whitesmith, Forester, Alma, Champagne, Trumpeter, Industry, High Sheriff, Tiger, Queen of Trumps, and Yellowsmith (silver-gilt Banksian medal).

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, C. T. Druery, H. B. May, C. E. Shea, W. Bain, H. J. Jones, D. B. Crane, E. Beckett, G. Gordon, J. Fraser, R. M. Hogg, and J. Walker.

Mr. B. R. Davis, Yeovil, staged a bright collection of Begonia flowers, double varieties only being represented. Amongst the best were Hercules, Albert Crousse, Salmon King, R. B. Parsons, Countess Temple, Mrs. W. H. Fowler, Exquisite, and Eldorado (silver Banksian medal). Mr. H. B. May, Upper Edmonton, sent a group of Aspleniums, comprising some dozens of distinct species and varieties (silver-gilt Flora medal). Messrs. F. Sander & Co., St. Albans, again sent plants of Watsonia Ardernei. Messrs. A. W. Young & Co., Stevenage, contributed a collection of hardy flowers in considerable diversity.

Sweet Peas from Mr. Henry Eckford, Wem, Salop, were very beautiful, and comprised some charming varieties. Very fine were Lady Grisel Hamilton, Salopian, Peach Blossom, Stanley, Dorothy Tennant, Prima Donna, Her Majesty, Lottie Eckford, Mars, Emily Eckford, and Blanche Burpee (silver Flora medal). Mr. B. Ladhams, Shirley, Southampton, sent a handsome collection of hardy flowers, comprising Campanulas, Achilleas, Chelones, Œnotheras, Coreopsis, Scabiosa, Potentillas, and others (silver Flora medal).

The usual position was occupied by Messrs. Barr & Sons, Covent Garden, with their hardy flowers. We noticed amongst the many others Gypsophilas, Sweet Peas, Calochorti, Irises, Phloxes, Alströmerias, and Gaillardias (silver Banksian medal). Messrs. H. Cannell & Sons, Swanley, sent a collection of seedling Begonias, the seeds of which had only been sown five months previously. The plants were dwarf, sturdy, and well flowered (bronze Banksian medal) Mr. John Charlton, Tunbridge Wells, exhibited a well diversified collection of herbaceous flowers (silver Banksian medal).

Mr. Jas. Douglas, Great Bookham, Surrey, sent a collection of fine Carnations, in which the most noticeable were Pelegia, Miss Violet Douglas, Badminton, Sir Henry Irving (these four received awards of merit), Zoe, Golden Eagle, Distinction and Garnet. Messrs. R. Wallace & Co., Colchester, staged Liliums, Calochorti, and Brodiæas in their customary excellent manner (silver Flora medal). Messrs. F. Cant & Co., Colchester, exhibited a charming stand of Roses, amongst which A. K. Williams, Susanne Marie Rodocanachi, Mrs. Frank Cant, Madame de Watteville, Madame Abel Chatenay, Maman Cochet, Madame Lambard, and several garden Roses were most conspicuous (silver Flora medal).

Messrs. J. Veitch & Sons, Ltd., occupied the whole of one side of a table with Coreopsis, Campanulas, Gypsophilas, Erigerons, Gaillardias, Phloxes, Lychnis, Scabiosas, Malvas, Iris Kæmpferi, and many other hardy flowers. The same firm sent also a number of Carnations and Picotees, which were clean and beautifully coloured (silver-gilt Banksian medal).

Messrs. W. Paul & Son, Waltham Cross, sent a collection of Roses comprising Sylph, Madame Ada Carmody, Waltham Standard, Milton, White Lady, Empress Alexandra of Russia, and others. The Water Lilies sent by Mr. J. Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury, were very beautiful.

Mr. C. Herrin, gardener to Lady Louisa Fortescue, Dropmore, was first for twelve bunches of hardy flowers; and Miss Debenham, St. Albans, for eight bunches.

CERTIFICATES AND AWARDS OF MERIT.

Begonia Miss Griffith (B. R. Davis).—A beautiful double variety, with large creamy-white flowers (award of merit).

Calochortus Plummeræ aurea (R. Wallace & Co.).—A very beautiful form, with bright yellow flowers (award of merit).

Lælio-Cattleya Canhamiana albida (J. Veitch & Sons, Ltd.).—The sepals and petals of this handsomely formed Orchid are white very slightly tinged with rose; the fine lip is rich velvety purplish maroon (award of merit).

Lobelia tenuior grandiflora (B. Ladhams).—This Lobelia, of which the many flowers are bright blue, grows to height of about 15 inches, and is very showy (award of merit).

Logan Berry (G. Bunyard & Co.).—This is an American plant, the growth of which resembles the Raspberry. The fruit is very acid, but should have some economic value. It is a profuse fruiter (award of merit).

Melon Syon Perfection (G. Wythes).—A medium-sized variety of handsome appearance. The flesh is deep scarlet and of exceptional depth. The flavour is very fine, and the aroma pleasant. The green skin is well netted. The parents were Syon House and Beauty of Syon (award of merit).

Nymphæa Ellisiana (J. Hudson).—A handsome variety with flowers of deep crimson hue (award of merit).

Nymphæa Marliacea albida (J. Hudson).—An immense white flowered variety of much beauty (first-class certificate).

Phaius Ashworthianus (F. Sander & Co.).—This is the result of a cross between P. Manni and P. maculatus. The sepals and petals are yellow and the lip crimson veined yellow (award of merit).

Platanus occidentalis argentea variegatus (J. Russell).—A singularly handsome leaved plant about 6 feet high. The foliage is green and silver (first-class certificate).

Rose Sylph (W. Paul & Son).—A new Tea variety of chaste beauty. The colour is cream suffused with rose and saffron (award of merit).

Salvia bicolor (W. Bain).—A very beautiful Salvia with lilac and white coloured flowers borne on spikes about 3 feet high. The plant is quite hardy (award of merit).

NAPHTHALENE.

THIS substance was noticed as existing in coal tar as early as 1820. Faraday first determined the composition of naphthalene, and Laurent greatly elucidated its chemical history. Now we have the substance in "cake" form and in "crystals." The coal tar, already having the lighter oil removed, is distilled in large iron vessels, and the oil which distils (after a certain portion has passed over) is treated with sulphuric acid cooled to 0°, when the naphthalene which it contains is deposited. Repeating the process, more naphthalene is obtained from the still liquid portions of the oil. Strained in cloth strainers, and pressed in bags to get rid of the adherent oil, the crude naphthalene is redistilled, and the result is "cake." This melted in basins, covered with paper so as to sublime, and then set aside to cool, colourless hexagonal crystals of naphthalene are found between the paper and cake in the basin. This pure naphthalene has the formula $C_{10}H_8$ = ten atoms of carbon and eight of hydrogen, or its rational formula may be expressed as $C_4H_4(C_2)C_4H_2$. It melts at about 80° and boils at 218°, sublimes—that is, wastes away, as camphor even at low temperature, and rotates upon water somewhat like camphor. Both, it is needless to say, are excellent germicides, and have been used a long time—camphor in rooms and naphthalene, as naphthal beta, in bee hives against foul brood germs, "bacteria."

Some time ago I drew attention to aniline as a safe and very cleanly insecticide for destroying aphides, thrips, and similar pests, briefly also alluding to naphthalene as a "cure-all" for the diseases to which useful plants are liable. Aniline (C_6H_7N) is obtained from benzole or benzene, discovered by Faraday in 1825, consisting of hydrogen and carbon (C_6H_6). This acted on by nitric acid produces nitro-benzole ($C_6H_5NO_2$), and this probably would tell more quickly as a fungicide and insecticide than aniline, which is obtained by treatment with nascent hydrogen, as the oxygen means burning up the "hides" of the vermin more quickly. When soluble, as it may by treating the derivative oil with potash and amalgamating, there would not be any harm to vegetable life of the higher forms either on the foliage or at the roots when used in moderation, and I am not certain whether this would not be better than naphthalene for the well-doing of the plant—that is, as a manure. Even aniline is a better substance as food than naphthalene, as in aniline (C_6H_7N) there is the nitrogen already; but in naphthalene ($C_{10}H_8$) the nitrogen does not come in until we produce the analogous substance, naphthylamine ($C_{10}H_9N$). Thus aniline and naphthylamine place the two substances on an equality, and both are very safe fungicides or insecticides—aniline, 1 in 20 parts water; and naphthylamine, 1 in 30 parts water. To place aniline on a level with naphthalene as a keen fungicide or insecticide we must pass the first back to benzene (C_6H_6), but naphthalene ($C_{10}H_8$) is the stronger.

Might is, as it always has been, the great thing in these days. The "big battalion," however, does not always win, and strength is a very bad thing for plants in the way of eelwormicide, fungicide, germicide, insecticide, and miticide, some of the prescriptions, either in themselves or in the manner of administration, being more harmful than the diseases produced by the infesting pests. I therefore go in for safety first and preventive or remedy afterwards, for the plant will aid itself to the best of its power and opportunities; hence the cultivator throws in pathological measures on the side of the plant, and this secured the killing of pests is a comparatively easy matter. Indeed, some cultivators so manage to grow things as to have very few pests of any kind, which may be due to particular conditions quite unassociated with the procedures of cultivation. But growers need no reminder of these things. What all aim at is the "big battalion" on their side and the little one on the opposite. The case is reversed when a strong fungicide or insecticide is requisitioned, hence naphthalene is preferred to benzene, naphthylamine to aniline, and naphthaline red ($C_{30}H_{21}N_3$) to rosalene ($C_{20}H_{19}N_3$). The two latter substances are used as dyes, and the refuse of the carpet manufacturer used as manure, and as such have been found extremely valuable for the freeing of the land from pests.

Make no mistake, there exists a relationship between naphthalene and benzene. Thus we have nitrobenzene and nitronaphthalene related to the parent substance in the same way, and from these nitro compounds reducing agents give rise to aniline and naphthalamine, from which again are obtained rosalene or base of the aniline colours, and on the other hand naphthalene red. The naphthalene is the stronger as a destroyer of pests, and the benzene the weaker as expressed by the formulas. If we look at the manurial or benefit to the plant side, nitrobenzene and nitronaphthalene are both manures of no mean order, as also are aniline and naphthylamine, and rosanilene and naphthaline red. The "kill" properties are more pronounced in the naphthalene than benzene, and this made soluble gives naphthalene superiority both ways, as the power to reduce organic matter in the soil is greater.

Thus the weight of evidence is in favour of naphthalene, and when this is made soluble we get something corresponding to soluble phenyle (C_6H_5)—namely, soluble naphthalene ($C_{10}H_7$), and with soluble benzene (C_6H_5). So much for the "killing" power—soluble naphthalene tops the lot, and to it I will now confine my remarks, and may say that to get full value out of it we must go a few stages further; but I am not going to bother the reader with any more chemical equivalents, only to

say that when we introduce potash to naphthalene we get naphthalene-potassium ($C_{10}H_8K_2$). Gardeners will smile—something again in return for spending money on a fungicide and insecticide—and, perhaps, rub their hands. Well, we get chemically additive and substitution products, which I will not follow only so far as to say that we add four atoms of chlorine to the naphthalene ($C_{10}H_8$), and thus secure a substance having the formula $C_{10}H_8Cl_4$, which surely Mr. W. Dyke will admit is a stinger, even for root eelworm. Too strong, well, it will kill either fungoid or insect pests, also plants of a useful character until made soluble and diluted to a safe strength.

This brings us to the crucial point. Naphthalene is not a particle of use as it is, and to make it of any use we must go back to the derivative—the coal oil; but this will not do, therefore get the lighter, clear burning oil = paraffin oil, which in solid form—that is, paraffin—amounts to about 0·12 per cent. of English bituminous shale. The oil, as everybody knows, is clear, and whether "boghead," or whence derived it may be, answers. Napthalene melts in that oil by the application of heat—that is, it goes back into the oil, and then this compound of naphthalene and paraffin oil saponifies by the addition of potash to form a softsoap, or with soda to form a hard soap. That makes all the difference, and one part of this as strong as it can be made in 1000 parts water—1 oz. to 6¼ gallons of water—kil's pests of all sorts.

All the preceding is laboratory work, which, as before stated, will not farther be followed, but enough has been said to let chemists work out a substance for us as clear as crystal, neither staining foliage, flowers, nor fruit, yet killing pests without nauseous smells, but such as a lady may use in boudoir for killing germs of disease, and preventing them from coming in. These are what we are coming to sooner or later, and everybody will be the better. But what we ordinary mortals, termed gardeners, want is for chemists to prepare for us a preparation of paraffin containing a certain percentage of napthalene, say 10 per cent. Chemists could do it easily by heat, but I do not advise my brothers of the spade to try, for fear of accident, as paraffin flares so when ignited, and too much heat spoils the whole affair, or may do worse.

Given the naphthalin-paraffin we can go ahead in this way :—Dissolve 1¼ lb. softsoap in a gallon of soft water by boiling, remove from the fire and add 2 gills (½ pint) of the compound whilst hot (not under 185°, and as near that as may be), stirring briskly till amalgamated, and then dilute with hot water to 13 gallons. This gives something like 1 in 2000 of naphthalene, 1 in 170 of paraffin, and 1 in 100 of softsoap. At that strength there is no danger of injury to tender foliage, whilst it would kill either fungi or insects in their young state. Then, in degrees upwards, it could be "stiffened" so as to suit mature or not tender foliage and hard-to-be-killed full grown or adult insects, bringing the naphthalene up to 1 in 1000, paraffin 1 in 85, and softsoap 1 in 50 by only diluting the compound to 6½ gallons. At this strength there is little danger of injuring the roots, and it certainly must kill all soil pests and afterwards act as manure.

The foregoing is a homely way of doing things, and could, no doubt, be improved upon; but I prefer to let chemists prepare more concentrated forms, such as naphthalin-paraffin compound. First get this—10 per cent. napthalin in paraffin oil; then, second, softsoap dissolved in an equal amount of rain water; and, third, take one part of naphthalin-paraffin and six parts of softsoap solution and emulsify. If that is not clear enough to the chemical mind, put it this way :—

Naphthalin	1 oz.	one part.
Paraffin oil	10 ozs.	
Softsoap...	33 ozs.	six parts.
Rain water	33 ozs.	

Amalgamate the naphthalene with the paraffin oil by heat, dissolve the softsoap in the water by heat, and at 185° add the naphthalene-paraffin, and thoroughly emulsify. Place in boxes or jars, and label naphthalene-paraffin-potassium compound.

Altogether there is some 4 lbs. of compound, and this will make 25 gallons of solution, sufficiently strong to kill aphides, without injury to the tenderest foliage. This is in the proportion of 1 part compound to 62½ parts water = 1 lb. compound to 6¼ gallons of water. The naphthalene, therefore, runs 1 in 4000, paraffin 1 in 400, and softsoap 1 in 120 parts water respectively. In ordinary practice softsoap is used in the proportion of 1 in 80 = 2 ozs. to a gallon of water, and petroleum 1 in 192 = a wineglassful (2 ozs. fluid) to 3 gallons of water. Naphthalene therefore strengthens up the compound, so that less paraffin and softsoap is used, for after all the new insecticide* is only paraffin emulsion naphthalenised. In the same way phenol could be used advantageously, and other substances of similar series.

To get at root pests we must come down to naphthalin or naphthalene (the older name) at lessened solution, 1 in 1000 of naphthalene being about the thing for disinfecting purposes, and then comes the question of safety for the plants when used during their growth. About 1 in 2000 is as much as root hairs can bear and some not that, so there must be judgment in these matters as in everything else. What may be done with paraffin-naphthalene emulsion remains to be seen, but I believe a patent has been applied for both in this country and on the Continent, but the whole business is well known to chemists, though the form is not such as the science would lead us to expect, for we want naphthalene in such soluble form as may be used at a strength of not less than 1 in 100 parts for root pests, when, but not before, it may rank with soluble phenyle, and similar preparations for effective use as eelwormicides, germicides, fungicides, insecticides, and miticides.—G. ABBEY.

* Paraffin-Naphthalene Emulsion, Pharm. Centralh xxxviii, 242 ("Pharmaceutical Journal.")

Notes & Gleanings

EVENTS OF THE WEEK.—The number of Rose Shows is now rapidly dwindling, and soon will be over for 1897. A list of those still to be held will be found on page 52. On Saturday, July 17th, the National Viola Society will hold its exhibition in the Royal Botanic Gardens, as will the National Carnation and Picotee Society on the following Wednesday.

—— WEATHER IN LONDON.—Though we have had many indications of rain in the metropolis during the past seven days, none has fallen. As a rule the days have been warm, but on one or two nights the winds have been quite cold. A warm, steady rain of some hours duration followed by fine weather would be greatly appreciated.

—— CARLISLE SHOW.—The schedule of the exhibition of the Carlisle and Cumberland Horticultural Society, to be held in the Drill Hall, Carlisle, on November 10th and 11th, comprises nearly sixty classes, some of which are open and others restricted. Some of the prizes are very good, while others are comparatively small, but it is hoped they will prove sufficiently good to insure a fine exhibition.

—— FREAKS OF TOMATOES.—I notice in your Journal of the 8th inst. a paragraph on the above subject, and your correspondent would like to know if any of your readers have had similar experience. I am an amateur, growing about forty plants, and have one plant which, after making eight leaves, instead of growing in the ordinary way, is crowned with five trusses. It has two fruits and about sixty blooms, some just setting, some fully expanded, and some not yet opened. The variety is Goldfinder. All my plants are from 3 to 4 feet high, and well set with fruit.—JOHN PILLMOOR, *Grove Terrace, York.*

—— MR. G. J. SYMONS.—The Albert medal for the present year has been awarded, with the approval of H.R.H. the Prince of Wales, the President of the Society of Arts, to Mr. G. J. Symons, F.R.S., "for the services he has rendered to the United Kingdom by affording to engineers engaged in the water supply and the sewage of towns a trustworthy basis for their work, by establishing and carrying on, during nearly forty years, systematic observations (now at over 3000 stations) of the rainfall of the British Isles, and by recording, tabulating, and graphically indicating the results of these observations in the annual volumes published by himself."

—— BIRMINGHAM SHOW.—The Chrysanthemum Show, annually held in the capital of the Midlands, has long been celebrated for its excellence — in fact it is one of the very finest of the provincial exhibitions. This year it bids fair to excel itself, for the Committee, desirous of showing the Society's loyalty to our Queen, has added £50 to the prize list, and in addition offers nine cups in two classes, the value of these ranging from £25 to £3. One is for a floral arrangement, and the other for a collection of fruit, but the particulars of these and the remaining eighty-eight classes may be had from the schedule. The dates fixed are November 10th, 11th, and 12th, in the Bingley Hall. Mr. J. Hughes, 140, High Street, Harborne, Birmingham, is the excellent Secretary, to whom all communications must be addressed.

—— IMPROVED VARIETIES OF FLOWERS.—In raising seedlings of ornamental trees, fruits, or flowers there are noted great variations in every character, from leaves to flowers and fruits. It is the practice of those who wish to improve or obtain new varieties to watch for such variations as may be in the line they desire to improve. For instance, a plant which usually bears entire leaves may have some seedlings with the leaves slightly lobed. If seeds are taken again from these the probabilities are that fine, cut-leaved varieties will eventually be obtained. So with the forms or characters of flowers. Any tendency noted in a seedling to vary in a line we may think to be an improvement is selected for seed, and in that way the desired improvements are secured in the progeny. The Germans, who are, says a transatlantic journal, famous for their patience, and are willing to wait two or three years for good results, are among the foremost in this branch of flower progress. Many improvements in garden flowers are made known to us by the efforts of German seedsmen, although the French are rapidly competing with them in this line.

—— GARDENING APPOINTMENTS.—Mr. G. Dance, general foreman at South Lychett Manor, has been appointed head gardener to Sir Elliott Lees, Bart., at the same place. Mr. E. Seal, gardener at Pownall Hall, Wilmslow, has been placed in a similar position at Sharston Hall, Northenden, the residence of R. Clay, Esq.

—— KENTISH STRAWBERRY CROPS.—In some parts of Kent this year the crop of Strawberries is quite phenomenal. From Sandwich alone during seven days over 100 tons of this luscious fruit were despatched. In one day the consignments exceeded 30 tons, requiring special goods trains to convey them to London. Large quantities, however, go beyond London to the great centres in the Midlands and the North, the average price being 1s. per gallon. There is now a very considerable acreage under Strawberry cultivation in Kent.—("Westminster Gazette.")

—— NEW YORK MARKETS.—The first new Apples, green and small, came from North Carolina recently, says a New York contemporary. Niagara Grapes, from Florida, are already offered here, a 3 lb. basket of large berried attractive bunches costing 45 cents. Other new-crop fruits are Currants and black and red Raspberries from Maryland, Delaware, and New Jersey. Water Melons and Musk Melons are now of good size and flavour, and sell readily. Choice English Gooseberries of immense size bring 20 cents a quart. Nectarines, from California, large and showy, cost 50 cents a dozen, and new Grape-fruit, from Jamaica, 25 cents apiece. Forty-four carloads of California fruits were sold here last week. Lemons have advanced 1·00 dol. a box during the past ten days, in anticipation of warmer weather.

—— THE LATE MR. WOODCOCK.—Under the heading of a "Public Loss," we take the following particulars from the "Eastern Evening News" of the 5th inst. "Mr. Woodcock began lecturing under the Norfolk County Council in 1892, and in consequence of the success attending his lectures he was given a permanent appointment in May, 1893, since when he has been continuously at work lecturing in school rooms or in the open air on the management of allotments and gardens; inspecting allotments for the award of the County Council prizes, and acting as Judge at the various county shows. The deceased gentleman was held in the highest possible regard by members of the County Council, who placed a high value on his labours. He had an immense store of experience in agricultural pursuits, and he had a happy knack of imparting his knowledge to others. Amongst cottage garden and allotment holders all over Norfolk he made a large circle of friends. Applications for his services were constantly being received at the County Council offices, and whenever he lectured he was asked for a second time. Personally he was a man of genial unobtrusive character. He had only attained the age of fifty-six. A pathetic circumstance in connection with the sad event is that at the meeting of the County Council on Saturday morning Mr. Lee Warner, as Chairman of the Technical Education Committee, speaking in ignorance that death had already taken place, expressed a cordial hope that Mr. Woodcock would soon be restored to health."

—— A NEW USE FOR SNAILS.—In Paris, as in London, there are critics who believe that Government clerks, who for the most part discharge their duties with zeal and punctuality, in return for a comparatively trifling salary, are in the possession of sinecures, and lead a butterfly existence. The latest story which has been circulated at the expense of the officials of one of the departments in Paris, is so droll that it has at least the saving merit of ingenuity. It seems to be meeting with any amount of credence, though it is hardly necessary to add that it should be accepted with the proverbial grain of salt. In order, as the narrative goes, to beguile the tedium of office hours the clerks have invented a novel kind of "sport"—to wit, snail races, which are run in a large and unused upper chamber under the roof. The snails are ranged at one end of the room, and at the other is laid a collection of vegetables, for which they naturally make with as much celerity as their rather inadequate means of locomotion will permit. But it is not entirely on level ground, in the shape of the floor, that the contest takes place. The excitement is increased by the fact that in their slow but sure career the snails have to surmount various obstacles ere the winning-post, represented by Cabbage leaves, Carrots, and so forth, is reached, so that the match partakes of the character of a steeple chase rather than of a race for the Grand Prix at Longchamps. A sweepstake is got up, and the winnings are pocketed by the backers of the liveliest snails. Such is the story, and already it has brought down upon the devoted heads of the unfortunate employés a heavy storm of reproaches, which, as may well be believed, are quite unmerited.—("Gardeners' Magazine.")

—— THE WEATHER LAST MONTH.—The prevailing direction of the wind was W. on sixteen days. Total rainfall 2·37 inches, which is 0·25 inch above the average for the month. This fell on thirteen days, the greatest daily fall being 0·72 inch on the 28th; barometer (corrected and reduced), highest reading 30·281 inches on the 12th at 9 A.M.; lowest, 29·316 inches on the 18th at 1 P.M. Temperature: highest in the shade 83° on the 13th; lowest 41° on the 10th. Mean of daily maxima 69·36°; mean of daily minima, 50·60°. Mean temperature of the month 59·98°. Lowest on the grass 37° on the 10th; highest in the sun 145° on the 28th. Mean of the earth at 3 feet 55·40°. Total sunshine 156 hours 40 minutes. There were three sunless days.—W. H. DIVERS, *The Gardens, Belvoir Castle, Grantham.*

—— ISLE OF WIGHT.—During the past week the Potato disease has spread with great rapidity in all parts of the Island. The varieties Late Rose and White Beauty of Hebron, from reports to hand, are the most badly affected. The cause of the disease is no doubt the dampness of the atmosphere, which, according to meteorological observations, stands out very prominently during the month of June. On six days the atmosphere was almost completely saturated, and the rainfall was greater than in any preceding June for the last ten years. Several thunderstorms have visited the Island, and the total rainfall for the month is 3·30 inches. In the valleys and sheltered situations the disease is most conspicuous. Peas, Grapes, and Onions are reported from various districts to be suffering from diseases, though not to an alarming extent, or anything in comparison to the Potato disease. The early Potatoes are turning out very well indeed, particularly Sutton's Ringleader, Early Regent, and Sutton's Seedling. The prices are, retail, from 3s. to 4s. a bushel in Newport, the capital and oldest market town in the Island.—S. H.

—— OLEARIA MACRODONTA.—Where this shrub will stand the winter it makes a welcome addition to the evergreens. Although it grows well and has stood unprotected in Shropshire it requires a very sheltered position to keep it unharmed about London. In any garden, however, where it does stand it is worth growing largely, as apart from the beauty of the graceful heads of white star-shaped blossoms during June and the early part of July, the leaves are beautiful the whole year round. During the summer the plant grows very fast, and probably this is the reason why it does not stand the winter well in some places, the shoots not getting thoroughly ripened. The leaves are very freely produced. They are ovate in shape with deeply dentated margins. The upper surface is deep olive green and very glossy, the under surface silvery. As cuttings can be easily rooted it is as well to keep a few small plants in a frame each winter to insure a stock in case of injury by severe frosts. It is a New Zealand plant, and is worth growing as a cool greenhouse plant where it cannot be grown outside, as it makes a good plant for decoration during winter.—K.

—— BATTERSEA PARK.—A proposal will shortly come before the London County Council for the construction of a suitable embankment along the whole river frontage of Battersea Park. The existing river wall is of a very slight nature, and a large proportion of it is in an extremely bad condition. The Parks and Open Spaces Committee of the Council, who are making the proposal, state that the present wall may be described as a mere skin of concrete blocks, generally 9 inches in thickness and in some cases less. For some years past it has been the practice to patch the worst places from time to time at an annual outlay of some £400 or £500. The result, however, has not been satisfactory, and the deterioration which has arisen in past years has not been overtaken, so that the wall is steadily growing worse. The Council's engineer reported in 1895 that the cost of putting the wall into a proper state of repair, if undertaken at that time, would be about £6000, and that even then there would be a subsequent annual charge of about £200 for its maintenance. Under these circumstances the Committee are firmly of the opinion that the best and most economical course would be to reconstruct the wall in a substantial manner. The length of the river front of the park is about 1300 yards, or about three-quarters of a mile, and the engineer is of opinion that a granite-faced wall with a granite parapet can be constructed there for the sum of £43,500. In view of the large recurring charge for maintaining the existing wall, and of the economy that would ultimately be effected by the substitution for it of a permanent granite embankment, and also taking into account the enhancement of the appearance of the park, the Committee strongly recommend the Council to adopt the scheme. It is proposed that the cost of the improvement shall be charged to capital account, the repayment being spread over the full term of the stock, out of the proceeds of the issue of which the cost would be defrayed.—("Garden.")

—— Adorning Liverpool.—At Liverpool an interesting experiment has been inaugurated. The Chairman of the Parks and Gardens Committee of the Corporation (Mr. Ball) has made a tour of some of the poorest streets, and has distributed about 500 window boxes and plants. The novelty of the procession (Mr. Ball was accompanied by large carts containing the boxes) naturally attracted great attention. No difficulty was experienced in obtaining ready helpers with the work, and great eagerness was displayed by the inhabitants to become possessors of the boxes. These have been given gratuitously upon an undertaking that the plants and flowers shall be well cared for, and a notification that if the gift is abused it will be withdrawn. Other districts please copy! Such a scheme will doubtless necessitate some supervision by the donors at the start, but it must ultimately tend to a considerable extension, and a corresponding demand for all sorts of plants, pots, boxes, seeds, and other requirements. What a rush there would be, says the "Irish Farmers' Gazette," for those window boxes if the Dublin Corporation would take the hint thus given by their Liverpool brothers. But there, we have no Parks and Gardens Committee here, and the only attempt made by our City Fathers to encourage a love for flowers among the poorer citizens is the distribution of a few scraggy Geraniums at the end of the year, when they are practically worthless to those on whom they are conferred.

—— Bananas.—The Banana trade of Santiago de Cuba has been much hindered and damaged by the long-continued war between the insurgents and the Spanish troops. The trade, at all events for the present, says Consul F. W. Ramsden, may be considered at an end as far as regards Baracoa, Sama, and Banes, but Gibara still produces the fruit. Baracoa in 1895 only exported 1,019,567 bunches, or about two-thirds of its average, this decrease being due to the cyclone which on September 23rd, 1894, destroyed a great many of the plantations in the districts of Sabana and Gran Tierra. In the year 1895 the Cuban insurgents sacked and burned the town of Sabana, causing damage to the extent of about 1,000,000 dols. The Baracoa crop of 1896 has simply been allowed to rot in the country, as it has been impossible to collect it, and exports only amounted to 2000 bunches, or, in other words, were virtually nil. Banes exported in 1895 807,000 bunches, and 755,000 in 1896, which is about three-quarters of the previous crop of 1894; but the place is now entirely abandoned, having been evacuated in August, 1896, and shortly afterwards burned by the insurgents. Sama is also abandoned, as far as the plantations are concerned. Sama exported 608,000 bunches in 1895, and 550,000 bunches in 1896, both of which crops may be considered as average ones. Gibara exported 1,415,000 bunches in 1895, and 1,305,000 bunches in 1896, which are also good average crops, and which for the immediate future are the only exports of this fruit likely to be realised. It may therefore be considered, says a contemporary, that the former total production of Bananas on the north coast of this province, amounting in round numbers to about 4,000,000 bunches, will now become reduced to one-quarter.

—— The Southampton Horticultural Society.—The executive of this well known southern Society, in spite of its now, in the light of its troubles, absurd prefix "Royal," and of the announcement made with respect to its proposed summer Show on July 31st, is yet an object of sincere sympathy. Its former lease at Westwood having expired, it is absolutely without a habitation, not having a place in which to hold its shows. Seeing, however, that the Borough Corporation, the custodians of the huge area of some 300 acres on the north of the town, had granted the Bath and West of England Agricultural Society leave last year to enclose some 30 acres of this common to erect needful sheds for its Show held a few weeks since, the horticultural executive, being a purely Southampton body, naturally thought that the Corporation would not be less generous in their case, and grant not 30, but about 6 acres, for the purpose of holding their Show at the end of the present month. After a good deal of equivocation, the assent was at last grudgingly given, although asked for this one season only. As a consequence, the executive have issued a schedule, made all needful contracts and engagements, and have largely advertised the Show; but it is even now, at this moment of writing, uncertain whether the Show can be held on the Common. A meeting of the Corporation will be held on Wednesday, July 14th, and a great effort will be made by a number of undoubted dog-in-the-mangerites to rescind the sanctioning resolution. It is earnestly hoped that the Corporation will not stultify itself by altering its previous decision. To do so would be indeed cruel and vindictive. The inhabitants of the town have immense areas for recreation, and the enclosure of 6 acres on the Common injures them nothing, whilst the Flower Show is with the people wonderfully popular. —A. D.

—— Fruit in Surrey.—After seeing how very moderate is the fruit crop over in the Middlesex market gardens I have been surprised to find that there are parts of Surrey where the crop of certain fruits is excellent. Thus the other day at Roehampton, looking through Dover House gardens, I saw Apples in abundance, hardly a tree being fruitless. Pears were thinner, and Plums almost nil. A day or two later, when looking through numerons gardens about Reigate, I found trees literally heavily laden with Apples in all directions. Pears were fair, Plums thin, and bush fruits plentiful. Then a day later, down in the Clandon and Merrow districts, Apples again were fairly abundant, some trees very heavily cropped. Pears fairly plentiful, Plums few, and Gooseberries and Currants in great abundance. Of these latter many bushes in the cottage gardens were almost breaking down with the weight of fruit. Such experience naturally renders it difficult to fairly estimate the probable fruit crop of the season, and the general returns are therefore looked for with exceeding interest. With a season that bids fair to be equal to the best of past seasons in vegetable, corn, and grass production, for these crops in every direction are splendid, it will be a misfortune if the fruit crop should prove to be really bad generally. So far as Strawberries and Raspberries are concerned, we know both crops have been, or are, good.—A. D.

ROYAL HORTICULTURAL SOCIETY.

EXAMINATION IN HORTICULTURE.—April 6th.

We have pleasure in placing before our readers the list of candidates in this examination in the order in which they were placed by the examiners. The report preceding the names will be found very interesting.

Examiners' Report.

To the President and Council of the Royal Horticultural Society.

Gentlemen,—We beg leave to report that we have examined the papers submitted to us—in all 184.

Of these we selected 89 as worthy to be placed in the first class, 55 in the second, and 28 in the third. The remainder (12) are not placed, the number of marks attained being below 100.

The distribution of the examinees were 169 in England, 6 in Scotland, 1 in Ireland, 1 in Wales, and 7 gave no address.

The present examination shows a very considerable improvement upon the results of that held in 1896. This will be apparent from the following comparison of percentages:—

Those not classed are only 12 in number, or nearly one-third of that last year (34).

The percentage of the third class (100 to 149 marks) has fallen from 32·2 (1896) to 15·2 (1897).

The percentage of the second class (150 to 199 marks) is nearly stationary—viz., 34·8 (1896); 29·8 (1897).

The percentage of the first class (200 to 300 marks) has made the astonishing increase from 10·5 (1896) to 48·3 (1897).

These results are most encouraging. Speaking generally, the answers are extremely well done. The information is accurate upon the whole, and the subject matter well expressed. Perhaps the "Practical Horticulture" showed, as might be anticipated, a slight superiority over the "Elementary Principles."

George Henslow.
Jas. Douglas.

The names and addresses of the successful candidates, together with the marks assigned to each, are given in the following Class List, to which is appended the questions set by the examiners:—

MAXIMUM NUMBER OF MARKS OBTAINABLE, 300

	First Class.	No. of marks gained.
*1	H. S. Langford, Horticultural College, Swanley	300
2	Miss F. M. Broade, Horticultural College, Swanley	288

QUESTIONS UPON WHICH THE EXAMINATION WAS BASED.

Eight questions only to be answered; four from Division A and four from Division B.

Division A.—Elementary Principles.

1, What are the three chief mineral ingredients of a soil? Name garden plants or shrubs which delight in each kind respectively.

2, What differences may be expected from growing unripe, perfectly ripe, and long-kept seeds respectively?

3, In transplanting, why is it necessary to preserve the extreme and most delicate tips of the root-fibrils?

4, Why does covering Rhubarb redden and lengthen the leafstalks and stop the growth of the blade?

5, Describe the structure of a Hyacinth bulb, and explain why the Dutch method of slashing or hollowing out the bottom induces the formation of bulbils?

6, What are the essential conditions for successful grafting?

7, How does the structure of a Plum differ from that of an Apple? Explain the origin of each.

8, Name the Natural Orders or Families to which the following plants belong:—Cyclamen, Rhododendron, Clematis, Stock, Pelargonium, Borage, Potato, Onion, Parsley, and Turnip.

Division B.—Horticultural Practice.

9, Explain the process of cross-fertilisation in garden flowers, and give examples of both hardy and exotic plants that have been improved thereby.

10, After seed of the Chinese Primula has been ripened describe the method of sowing and subsequent treatment of the plants up to the period of their flowering.

11, What is the native country of the Celery plant, and under what conditions does it grow naturally? Give a short account of its culture, such as time of sowing and subsequent treatment.

12, When and under what conditions is Seakale found in a wild state? Describe its culture, and state the time of the year it is in use.

13, Where is the common Asparagus said to be found in a wild state? State all you know of its culture, and for how long a period it may be had in use.

14, Give an account of the Apple. How are the trees propagated? State what you know of its culture, and the diseases to which the trees are liable, and the remedies. Name one good cooking variety for use in each month from August to April inclusive.

15, State all you know about the Raspberry. What sort of soil is best adapted to its culture? Give method of training and pruning, and the best varieties to cultivate, both yellow and red.

16, Give an account of the usual method of Gooseberry culture adopted in gardens; and also the Lancashire method to obtain prize fruit. Name six of the best prize varieties, and six best for ordinary garden culture.

Rose Show Fixtures for 1897.

July 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
,, 22nd (Thursday).—Halifax, Trentham, and Bedale.
,, 23rd (Friday).—Ulverstone.
,, 27th (Tuesday).—Tibshelf.
,, 28th (Wednesday).—Chester.*
,, 31st (Saturday).—Liverpool.*

* Shows lasting two days.

Three New Roses.

Roses become more and more numerous every year, but such is the enthusiasm displayed in their culture that no matter how many there are, they will, if of good quality, quickly secure supporters. Amongst the comparatively recent introductions that promise to become popular are Madame Abel Chatenay, Beauté Lyonnaise, and Souvenir de Madame Eugène Verdier, of which Mr. Charles Turner, Royal Nurseries Slough, sent us the photograph from which our illustration (fig. 9) is reproduced. Each variety is of great beauty, and is classed by the raisers as Hybrid Tea. Madame Abel Chatenay, which is shown on the left, is a handsome Rose with flowers of a rosy carmine suffused with salmon and buff. The flowers are of fine shape, especially in the bud state. At the top of the photograph is Beauté Lyonnaise, an almost pure white, full and globular flower, which is deliciously fragrant, while at the bottom we have Souvenir de Madame Eugène Verdier. This is a fine Rose, the colour of which is white suffused with saffron, and the bloom is of good shape. The blooms shown were taken from pot plants in Mr. Turner's nursery, and the flowers may vary a little in colour from plants in the open ground.

Medea, Maréchal Niel, Maman Cochet, and Muriel Grahame.

In the last number of the Journal (page 23) Rev. D. R. Williamson repeats his opinion that Medea is the equal of Maréchal Niel. He does not state it as his opinion, but as a matter of fact. It is my opinion, and I have grown and shown good blooms of Medea, that it is not fit to hold a candle to Maréchal Niel, which is far and away the finest yellow Rose known.

In his interesting report of the Hereford Rose Show "The Herefordshire Incumbent" alludes (page 29) to Maman Cochet as "long in bud, poor habit." This will surprise the many admirers of this splendid Rose, which if it were not rather late in blooming I should expect to see at the head of Mr. Mawley's analysis, for most of us find it a very good grower, of thoroughly vigorous habit.

I am in hopes that Mr. Lindsell has had a photograph taken of his grand bloom of Muriel Grahame, exhibited at the Crystal Palace, as it was quite worthy of being ranked with Mr. Burnside's Cleopatra and somebody else's Madame Cusin, and other specimen blooms of note. The shape and texture were perfect, and it looked as if it were capable of even further development.—W. R. Raillem.

Rosa indica var. sanguinea.

Of the many varieties of Rosa indica none is prettier or makes a more charming effect than this. Like most of the class, it is an almost perpetual flowerer, and can be had in good condition, outside, from early in May until October. The flowers are blood red, semi-double, and 1½ to 2 inches across. These, however, are not the only attraction, for the young foliage is of a beautiful bronze, and adds greatly to the effect.

Like most of the class, it will pass through ordinary winters unharmed. In exceptionally severe winters, however, it is cut to the ground, but springs up again as warmer weather comes. As cuttings can be rooted with the greatest ease it is advisable to keep a fresh stock of plants growing, as after three or four seasons the old ones usually deteriorate. By rooting cuttings in July and potting them singly into 3-inch pots, then in February moving into 5 inch, good plants may be had for planting in May. They are not so much trouble through the winter as ordinary bedding "Geraniums," and if grown as bedding plants they will be found to give as great, if not greater, satisfaction than many of the plants usually used for the purpose.

The brilliant colour of the flowers, together with the freedom with which they are produced and the little trouble necessary to insure success, should make this one of the most popular of bedding Roses.—W. D.

Comments.

I have often noticed in passing through life how very seldom alterations of dates for any event are advantageous, and certainly in the case of the National Rose Society this idea has been strengthened. Twice during its career have dates for shows been altered, and in both cases with disastrous results. The exhibition at Chester in 1892, and that of Portsmouth in 1897, were altered at the request of the local Committees, and under such circumstances the parent Society has only to give way. In the case of Chester I believe it was utterly uncalled for, and the result was, that while the day originally fixed was very fine, that to which it was altered was as wet and unpleasant as it was possible for it to be.

As far as Portsmouth was concerned it was of course unavoidable. The day at first decided on was the one after the Jubilee celebration in London, and everyone felt that to hold a show on the day after a Bank Holiday, and such a holiday, when all the world was in an uproar, was quite impossible. I suppose the local Committee had its reasons for putting it back instead of forward, but at any rate the 23rd was a fine day, and the 18th, to which it was altered, was boisterous and wet; indeed, had it not been for the exceptionally strong manner in which the tents were secured the York catastrophe would have been repeated. There were other causes also which interfered with the exhibition. The season was a late one, and consequently putting the show back was unfavourable to it; and then again the local Committee was unfortunate in losing the services of a gentleman who for twenty years and more had managed the Ryde Show, but who through domestic affliction was unable to be present.

I may add yet another item that was unfavourable; the show was held in two tents instead of one large one, and though they were contiguous to one another, it created a difficulty which is always experienced in such cases. One of the tents was devoted to the exhibition Roses, and the other mainly to garden Roses, and when an exhibitor is wanted in one of these he is sure to be in the other. All this militated against the success of the arrangements, and though Captain Ramsay exerted himself to the utmost, complaints were made that the judging did not commence at the time it was announced to do; in fact, this is nearly always the case at all shows, and the fault is generally not with the executive, but with the exhibitors. With these unfavourable circumstances it is not to be wondered at that the exhibition was the smallest in extent and, I think, the poorest in quality that the National has ever held.

Many of the leading exhibitors, both professional and amateur, were absent. Neither Messrs. Harkness & Sons, nor the East Anglia amateur Tea growers, Messrs. Foster Melliar, Orpen, Berners or Page Roberts were there; neither was the champion grower, Mr. E. B. Lindsell. The two classes which most interested both exhibitors and visitors were those for the cup presented by Capt. Ramsay for twelve blooms, and that for the Prince Memorial cup for eighteen Teas. In the former the prize was given to a beautiful box exhibited by Mr. A. Tate of Downside, Leatherhead, and I think it was impossible that such blooms could be shown without protection of some sort having been given to them. This stand was remarkable also for containing the two medal blooms in the amateurs' division for the best H.P. and the best Tea, the former being won by a beautiful but not very large bloom of Mrs. John Laing, and the latter for the best bloom of Madame de Watteville I ever saw staged. The Prince Memorial cup was won by Alex. Hill-Gray, Esq., Beaulieu, Bath, with a fine stand of eighteen blooms of fair size and excellent quality. It was anticipated that there would have been much keener competition in this class, but for the reasons I have already mentioned many failed to put in an appearance, and the other prizes were awarded to almost unknown exhibitors.

It was hardly likely that at so early a date and in such a season that there would be many noticeable flowers, and certainly there is nothing in the newer varieties which calls for special notice. There were good blooms of Medea, especially considering that it is a Rose that requires a warmer season. White Lady, which is a creamy white sport from Lady Mary Fitzwilliam, was shown in fair condition. Golden Gate is another pleasing Tea, and was placed in several stands. It is not, as persons might be inclined to think from its name, a yellow Rose, but is a creamy white of good form. Captain Hayward is a Rose of brilliant colour, though perhaps not quite so full as one might wish, yet cannot be dispensed with, and appeared in several stands.

It is not, however, too much to say that the chief features of attraction were the collections of garden Roses. They were, as I have said, in a separate tent, and it was a great pity that more space was not awarded to them. If more room had been left between the boxes they would have made a better display. The Committee of the N.R.S., being afraid that the late season and the early date would militate against the exhibition Roses, had at the last introduced some extra classes which helped to fill up the tent. There were but few competitors in any of the classes, and the chief interest was centred in the large class of thirty-six for nurserymen, where Messrs. Cooling & Sons of Bath carried off the principal prize. Amongst their flowers I noticed Marquis of Salisbury, most brilliant in colour; W. A. Richardson, which in its way has not been beaten; Bardou Job, very bright; Macrantha, pure white; the true York and Lancaster, not the Village Maid or Gloria Mundi which so often do duty for it; Isabella Sprunt, a bright yellow; Commandante Beaurepaire, a brilliantly striped Rose; Anne of Gierstein, one of Lord Penzance's Briars; Gloire des Polyanthas; Homère and other well-known favourites. There were beside these two not usually seen, Lucida Plena, a double variety of the pretty old Lucida, and Purity, a seedling

raised by Messrs. Cooling & Sons, most floriferons and likely to prove a most usefnl flower both for garden purposes and exhibition.

In the amateur division Mr. A. Tate of Leatherhead occupied the chief position, and amongst his flowers were Alister Stella Grey, which was very well shown, and is an exceedingly pretty garden Rose, very free flowering and very vigorous. There was also a good bunch of the Crested Moss, a Rose which is not very often seen and always attracts people by its curious buds. Mr. Campion of Reigate and Miss G. Carter of Ryde were also successful exhibitors. People sometimes wonder that there are not more exhibitors in this class, but the flowers require a great deal of trouble in bringing them to the exhibition tent.

There are one or two regrettable incidents, one in which Messrs. Frank Cant & Co. were disqualified for a Rose, unnamed, and marked as a sport from Susanne Marie Rodocanachi. It was only last season that a somewhat similar case occurred, and the Committee decided that it was irregular; the sport may not be a fixed one, and may revert to the type. The other case was that of a local exhibitor, where duplicates were shown, two blooms of Charles Lefebvre being in the stand and one bearing the name of Camille Bernardin. The exhibitor stated that she had received it from the grower of whom she purchased it under the name of Charles Lefebvre, and consequently the case was a very hard one, but still the Committee can have but one rule by which to go, however hard its application may seem at times

The Judges and exhibitors were hospitably entertained in the beautiful new Town Hall, which adjoins the park where the Exhibition was held, by Mr. Alderman Evans, who introduced the happy innovation of dispensing with toasts; in fact everything was done that lay in the power of the local people to remedy those evils over which they had no control.—D., *Deal.*

FIG. 9.—THREE NEW ROSES.

BRIEF NOTES ON ALPINE FLOWERS.

(*Continued from p.* 11.)

DIANTHUS ALPINUS.

THE dwarf Dianthi are deservedly favourites with growers of alpine flowers, and a good collection of such plants generally contains at least a proportion of these Pinks. Some growers are rather unsuccessful in retaining them for more than a year or two, and the species under notice is one which gives some trouble to these cultivators. I do not pretend to offer a panacea certain to remove these difficulties, but if one can state the conditions under which Dianthus alpinus succeeds in some gardens it may be a help to those who have hitherto failed with it.

In order to raise a satisfactory stock of plants to begin with it will be found a good plan to obtain a packet of seeds. Seedlings are, as a rule, more vigorous than plants from cuttings or divisions. Seeds can be procured from some seedsmen, and with proper treatment germinate quickly and satisfactorily. Take a pot or pan and fill it nearly half full of drainage, composed of broken pots properly laid so as to allow free drainage. Fill up to within an inch of the top of the pot with light soil composed of equal parts loam and leaf mould, with a good dash of silver sand thoroughly mixed. Press the soil firmly so as to make it level, but not too hard.

On this sow the seeds thinly, and cover these with about a quarter of an inch of similar soil, sifted through a fine sieve. Press this gently down with a flat piece of wood or metal, water gently, and place the pot or pan in a cool shady frame or in a cold greenhouse. Take care that the surface of the soil does not become too dry. To prevent this, without giving too much water, it is a good plan to cover the pot with paper, removing this gradually as soon as the seedlings appear. When these make their appearance they ought to have air and light, but need to be shaded from strong sun. As soon as large enough to handle the seedlings should be pricked out about an inch apart in other pots or boxes filled with similar soil. When a little larger they may be planted out in the places they are intended to occupy. Care must be taken to prevent the young plants from being destroyed by snails or slugs, which are often destructive to both young and old plants.

This Alpine Pink succeeds best in a rather gritty soil, with a good admixture of peat or leaf mould and sand. Here it is found to thrive best on a rather elevated terrace of the rock garden, and where it has full exposure to the S., S.W., and W. It is thriving admirably in this position, whereas on lower and moister terraces it could not be persuaded to live long after flowering. It has also been seen to do well only a little above the ordinary level, but facing due south, and in dry gritty soil, in front of a greenhouse. It appears to be partial to dry soil in the climate of Great Britain, and provided the arch enemies—the slugs—are kept from it, there should be little difficulty in many gardens if this advice is followed. This note is long enough to be hardly in keeping with the word "brief" at the head of these notes, but the beauty of this exquisite little flower warrants one in straying somewhat from our usual in speaking of its requirements. Its beautiful deep rose flowers with crimson spots, and produced so freely on the dwarf stems as to cover the foliage, are worthy of our highest praise amid the rival claims of the gems of the alpine flora. So charming a flower deserves full notice.

ONOSMA ALBO-ROSEUM.

It is unfortunate that this pretty and distinct alpine is even less amenable to cultivation in our climate than the more showy O. echioides, which was spoken of on p. 10, and illustrated on the following page. Whatever may be the reason, it usually succumbs after having been grown for a year or so, even if protected overhead from the winter's rain. The leaves appear to dry up gradually, and the plant in time becomes weaker until it finally dies off. One would like to be able to say that this can be avoided, but so far as we know the plant can only be depended upon as a biennial, to be raised from seed, which is not readily obtainable. Sometimes young, fresh shoots may be taken off with a heel and struck in a similar manner to those of O. echioides; but these are seldom produced, and cannot be relied upon, so far as it has come under the writer's observation in his own garden and elsewhere.

O. albo-roseum is much less robust in its habit of growth than O. echioides, and its pretty white flowers have a tendency to hide themselves more than those of the better known species. Altogether it cannot be said that it is a satisfactory plant, nor one to be recommended to the ordinary grower of alpine flowers. The flowers are similar in form to those of O. echioides, and the foliage, which is lighter and more greyish in colour, is also hairy. O. albo-roseum is a native of Asia Minor, &c.

SAPONARIA CÆSPITOSA.

It is not to be supposed that high-priced or rare plants are necessarily the best of those in the genera to which they belong. Unless in the case of newly introduced plants a high price is generally an indication that the species offered is difficult of propagation, or is not very satisfactory under cultivation. This little Soapwort may be included in the latter class, and those who wish to have a satisfactory representative of the Alpine Saponarias cannot do better than grow S. ocymoides splendens, although this also presents difficulties in some gardens.

The one under notice comes from the Pyrenees, and its defects in gardens are its shy flowering and liability to destruction from slugs. I grew it for several years, but had only the pleasure of seeing a flower

to two occasionally during that time. This will not prevent some from trying it, and, for the benefit of these it may he said that this "Tufted Soapwort" is a neat habited plant, with its linear leaves in tufts like those of a dwarf Thrift. The flowers, should they he formed, may be expected to appear in June or July, and are produced a few together in a cluster on very short stems. They are bright rose in colour. S. cæspitosa likes a sunny airy position in sandy soil. It is increased by division or by seed.—ALPINUS.

(To be continued.)

HORTICULTURAL SHOWS.

FARNHAM.—JUNE 30TH.

THE twenty-seventh annual Show of the Farnham Amateur Rose and Horticultural Association was held in the Gardens of Farnham Castle on Wednesday, June 30th, by the kind permission of the Bishop of Winchester. The Show was certainly one of the largest and best that has ever been held by the Society, and the four large tents were closely packed with exhibits, which even overflowed on to some staging placed under the Castle wall.

In the open classes for Roses there were some splendid blooms exhibited, Mr. Taylor of Hampton being first in the class for twenty-four; Mr. West, Reigate, second; and Mr. Bide, Farnham, third.

It is, however, in the members' classes that one best sees how strong a hold Rose growing has taken in the neighbourhood, for in the class for the Association's challenge cup there were as many as twelve competitors. Mr. Knight, Leigh House, one of the oldest and most successful members of the Society, was first, with Mr. Anderson of Waverley Abbey, an equally successful member, and donor of the present challenge cup, second.

Mr. Knight also showed the best bloom in the members' classes in a "Her Majesty," Mr. Anderson's Catherine Mermet being the best Tea. The best bloom in the whole show was, however, found in the open classes, an Ulrich Brunner, shown by Mr. West.

If Roses were good at the show, herbaceous plants were better, and the two large exhibits, not for competition, made by Mr. Prichard, Christchurch, Hants, and Messrs. G. Jackman & Co., Woking, were quite the grandest feature of the show, completely filling as they did one of the tents. The local exhibits of hardy flowers were also good.

The arrangement of flowers in vases and haskets has always been noteworthy at this show; and this year, though hardly as many as last, the tasteful decorations showed that the hands of the ladies of the district had not lost their cunning. In groups of plants, General Marsack was first with a fine arrangement, containing many Orchids and other good things, the Bishop of Winchester being second with a group nearly as good. Strawherries were not so good as last year, and the same may he said of Potatoes and Peas, but there were some fine dishes of Tomatoes shown.

During the afternoon the mounted band of the Royal Artillery played on the lawn of the Castle, and at five o'clock the prizes were distrihuted by Mrs. Davidson, the wife of the Bishop of Winchester.—M. P. T.

HANLEY.—JULY 2ND.

WELL done, Hanley! may be exclaimed on this the first attempt of the busy Staffordshire town to hold a flower show, and the promoters of it are greatly encouraged by the satisfactory results that are forthcoming. The show was held in the new park, which is 85 acres in extent, with all the modern conveniences, grand buildings, a fine lake, and well-kept grounds. Five years ago this place was a disused fen and swamp, now it is a most enjoyable place for the recreation of the public. One can hardly imagine in the densely populated district to find such an extensive place. There are many difficulties also to overcome in gardening, for the park is surrounded by manufactories. Various styles of gardening suitahle for the district are well carried out, over 200,000 plants of various kinds having been bedded out. The grounds are hilly, there are fine terraces, and the place is greatly appreciated by the inhabitants.

A better arranged show we have never seen for a first one. Four enormous marquees were arranged side by side, all being provided with that grand illuminant at night, the electric light. This was a great novelty and happy introduction; the plants, flowers, and fruit looked remarkably well under the strong light. Water was also laid down in each tent, while in the Secretary's office a post office and telephone were introduced, to the great satisfaction of many. To Mr. Joseph Kent, the Superintendent, we offer our congratulations upon the splendid arrangements he made for the exhibitors; everything was well studied and as well carried out. The show was a great success in every way; over 20,000 people paid admission the first day, and considerably more, we should say, the second day. There is a most promising future for this Society, which we trust it may long live and prosper.

The principal feature at most shows now are the groups arranged for effect. It was so here. With 300 square feet groups there were five competitors. Various strong opinions were freely expressed by many regarding the awarding of the first prize, which went locally to Messrs. Jenkinson & Son, Newcastle, Staffs, but many persons thought the second should have had the honoured position—viz., that shown by Messrs. J. Cypher & Son, Cheltenham. The prize was £20 and a special "heraldic porcelain flower centrepiece," presented by Mr. W. H. Goss. In the class for a group of Orchids arranged for effect, in space not exceeding 100 square feet, Messrs. W. Thompson, Stone, Staffs, and Messrs. J. Cypher & Son were the successful competitors. These famous exhibitors also took premier honours for specimen plants in flower, Palms, Ferns, and Orchids. Other successful exhihitors in the above classes were the Duke of St. Albans, and Messrs. C. H. Wright, Oswestry; W. Vause, Leamington; F. Maddock, Alsager; and A. S. Dix, Skelton.

Roses were admirably represented, as will be understood from the prize list as under. Forty-eight distinct varieties.—First and special (presented by Messrs. Beck & Moss), Messrs. A. Dickson & Son, County Down, Ireland; second, Messrs. Harkness & Sons, Bedale, Yorkshire; third, J. Townsend & Sons, Broadheath, Worcester. Thirty-six distinct varieties, three blooms of each variety.—First and special (presented by Mr. Pennington), Messrs. Harkness & Sons; second, Messrs. J. Townsend and Sons; third, Messrs. A. Dickson & Sons. Twenty-four distinct varieties.—First, Messrs. J. Townsend & Sons; second, Messrs. A. Dickson & Sons; third, Messrs. Harkness & Sons. Twelve distinct varieties.—First, Messrs. A. Dickson & Sons; second, Messrs. J. Townsend and Sons; third, Messrs. Harkness & Sons. Twelve distinct Teas, three blooms of each.—First and special (presented by Mr. R. Hastings), Messrs. J. Townsend & Sons; second, Messrs. A. Dickson & Sons. Decorative arrangements of Roses, not exceeding 12 feet by 5 feet.—First and special (presented by Mr. J. R. Howlett), Messrs. M. Jenkinson & Sons; second, H. Chandos Pole Gell; third, Messrs. J. Townsend and Sons. Twelve Hybrid Perpetual, one variety.—First, Messrs. A. Dickson & Sons; second, Messrs. J. Townsend & Sons; third, Messrs. Harkness & Sons.

Fruit and vegetables were excellently represented. Good collections of fruit were staged; black Grapes were very good, but many bunches of white Grapes were not finished. It seems a pity to cut Muscats so green, though the bunches were very fine. The prizes in the chief fruit were adjudicated in the following order:—Collection of nine dishes of fruit.—First and special (presented by Messrs. Bratt and Dyke) and second, divided between the Earl of Harrington and Lord Bagot; third, Duke of St. Albans; fourth, Earl of Carnarvon. Two bunches Black Hamburgh Grapes.—First, Lord Bagot, Rugeley; second, Earl of Harrington, Derby; third, Alderman Ridgway. Two bunches black Grapes, any other variety.—First, Earl of Carnarvon; second, Lord Bagot; third, H. H. France Hayhurst, Wellington. Two bunches White Muscat Grapes.—First, Lord Bagot; second, J. Bratton; third, T. Bolton. Two bunches of Grapes, any other variety, white.—First, Earl of Carnarvon; second, Lord Bagot; third, J. C. Waterhouse. Six Peaches.—First, Mrs. Meakin, Cresswell Hall; second, Duke of Sutherland; third, C. H. Wright. Six Nectarines.—First, Earl of Carnarvon; second, Duke of Sutherland; equal third, Lord Bagot and Mrs. Meakin. One Melon, green-fleshed.—First, H. H. France Hayhurst; second, B. Fitzherbert, Swynnerton Park; third, J. C. Waterhouse. One Melon, scarlet-fleshed.—First, Duke of St. Albans; second, Duke of Sutherland; third, Lord Bagot. In the class for a collection of nine dishes of vegetables, first and special (presented by Mr. J. G. Fenn, Stoke-on-Trent) Lady Guest; second, Earl of Carnarvon; third, H. H. France Hayhurst; fourth, C. H. Wright.

Commendable and successful endeavours were made to encourage school children to grow plants and flowers, and exhibit bouquets. This section was under the patronage of a special Committee, with the Mayoress as President. The object of the Committee was, as far as possible, to encourage, especially amongst the poorer portion of the inhahitants, a love of flowers, and the knowledge and method of their cultivation. Subscriptions, limited to 1s. each person, were invited, and these were devoted to the purchase of prizes. Rooted cuttings were supplied to the children who applied for them by Mr. Kent, the donors being Messrs. Wallis of Keele, Roherts of Oswestry, Bolas of Wirksworth, and Hill of Spot Acre, whilst Mr. R. Sydenham, of Birmingham, gave a large quantity of seeds. Numerous prizes were forthcoming, and the result was a very successful show, in which great interest was taken. There were over 350 entries, and the exhibits were excellent in quality. The Mayor of Hanley, M. Tunnicliffe, Esq., opened the show, and also presided at the luncheon. In all respects the exhibition appeared to be a gratifying success.

DISS.—JULY 6TH.

WANTED, by a gentleman beginning to call himself elderly, and obliged to do all his work himself, a nice quiet Rose show, in a secluded country spot, where he can escape such severe competition as is to be found in the company of Messrs. Orpen and Pemberton. Diss seemed to answer the advertisement, but things are not always what they seem. The show was held in the Rectory grounds, which are conveniently close to the station, and moreover have the reputation (not lost in this instance) of securing fine weather for the Rose show.

In the trade class, thirty-six Roses, Mr. B. R. Cant was easily first with a fine stand. His most remarkable Rose was a magnificent bloom of Luciole, wonderful in size, shape, and colour. Soft as this Rose is, with not many petals, it often "stands" well, and I believe has generally been in Mr. B. Cant's seventy-two at the Palace. It ought, I think, to be restored to the N.R.S. list of exhibition Roses. A grand bloom of Mrs. Sharman Crawford, with good examples of La Boule d'Or and Comte Raimbaud, were also here. Messrs. Frank Cant & Co. were second, some way behind, but a fine specimen of Victor Hugo, which has been good this year, was shown by him.

In the amateurs' class, of twenty-four Roses, for the challenge cup in memorial of Mr. Frere, Mr. Orpen was a good first, his magnificent Teas and neat method leading him to a decided victory. Comtesse de Nadaillac. Cleopatra, Maman Cochet, Madame Cusin, and Kaiserin Augusta Victoria were among his best. Rev. A. Foster-Melliar was

second, his best Roses being Charles Lefebvre, Mrs. Paul, and Horace Vernet. Rev. J. H. Pemberton third, his best being Charles Lefebvre (which beat Mr. Foster-Melliar's Rose of the same variety by a shade for the best amateur H.P.), and a good example of Charles Gater.

For twelve Teas (amateurs), Rev. F. Page Roberts was first, with good specimens of Ethel Brownlow and Catherine Mermet. Mr. Orpen was not more than a point behind, showing neatly and cleanly as usual. Mr. Foster-Melliar was third, his Souvenir d'Elise gaining the prize for the best Tea, as it will when perfectly shaped.

Mr. Page Roberts was first again with twelve Roses, showing a good Horace Vernet. Mr. Frank Cant showed some interesting garden Roses. The herbaceous classes were well filled—as they always are at this show, and the five dinner-table decorations created a good deal of interest. Some people may sneer at these classes (dinner-tables), but I am of opinion that they have done a great deal of good. I can see a very large advance in taste and grace in these matters during the last fifteen or twenty years, and I give these classes not a little credit in art education.

IPSWICH.—July 7th.

This show was held in the Upper Arboretum, and was favoured with fine weather and a good company. The Secretary, Mr. Archer, was absent through indisposition, but things worked fairly smoothly with the help of an energetic Committee.

In the trade classes Mr. B. R. Cant was first for thirty-six, Susanne Marie Rodocanachi, Horace Vernet, and Duchesse de Morny being among his best. D. Prior & Son second, some way behind, with a grand Maréchal Niel, rather "altered in character," and good specimens of Horace Vernet, Mrs. J. Laing, and Her Majesty. Mr. Green of Horkesley, the new Colchester professional, was third.

In twelve trebles Mr. B. R. Cant was first, showing Her Majesty and Mrs. John Laing well. Messrs. Prior & Son were not far behind, they, too, showing Mrs. J. Laing in good condition. In six H.P.'s of a sort Messrs. Prior won and Mr. Green was second, both with Mrs. J. Laing. In six Teas of a sort Messrs. Prior were very easily first with Maman Cochet, Mr. Green following at some distance with Marie Van Houtte. In twelve Teas the pointing was very close, two fine blooms, Innocente Pirola and Maman Cochet, giving Messrs. Prior the premier position over Mr. B. R. Cant, who had Cathorine Mermet and Madame Cusin in good order.

In garden Roses Mr. Green was first, Hon. W. Lowther of Campsea Ashe second, and Messrs. Prior third. The latter should hardly have got even the third place, for Madame de Watteville, well thinned, can scarcely be called a garden Rose, even under elastic conditions.

In the amateurs' classes there was not quite such high pressure competition, and a certain person or persons breathed more freely, and seemed generally more at ease. For twenty-four Rev. A. Foster-Melliar was first, Victor Hugo and François Michelon being among his best; Rev. H. A. Berners second, showing evident signs of the end of the season. In six trebles the position was reversed, the second prize stand being rough and coarse. In twelve Roses Rev. A. C. Johnson was first, Mr. Warnes of Eye second, and Mr. Berners third.

For twelve Teas Mr. Foster-Melliar was first with a good stand, Maman Cochet and Maréchal Niel being perhaps his best; and Mr. Berners second. The same order was observed in six H.P.'s of a sort, Mr. Foster-Melliar being first with La France, Mr. Berners second with Marchioness of Londonderry, and Mr. Haines third with Her Majesty. For six Teas of a sort Mr. Berners was easily first with Maman Cochet, Mr. Foster-Melliar second with Comtesse de Nadaillac, and Mr. Warnes third with Souvenir de S. A. Prince. In six Teas, distinct, Mr. Warnes was first, and Mr. Johnson second. There were two classes of dinner tables, some nine or ten being shown by amateur ladies, but they should remember that in the opinion of some judges all coloured drapery is objectionable, and ribbons are detestable.

TUNBRIDGE WELLS.—July 7th.

This, the thirty-ninth year of the above Society, was a really good show as regards Orchids, Roses, and stove plants. Fruit fell off very much, and there was also a decided decline in the number and quality of floral designs.

In the open class for four stove and greenhouse plants Mr. N. Turner, gardener to J. A. Le Lacheur, Esq., The Wilderness, Tunbridge Wells, beat Mr. J. Mason, gardener to H. J. Wood, Esq., Tunbridge Wells. Mr. S. Pope, gardener to J. J. Barrow, Esq., Holmwood, was well ahead for ornamental foliage plants, also for four and six stove and greenhouse plants in bloom, but was beaten by Mr. J. Mason for six ornamental foliage plants in the local classes. Mr. L. Dupond was first for single, and Mr. C. Dunk for double Begonias. One of the features of the show was the grand Caladiums from Mr. N. Turner.

Groups were good again, the first and second going to Mr. J. Howes, gardener to W. Cobb, Esq., Dulcote, and Mr. J. Mason. Orchids were excellent, especially Epidendrum vitellinum majus, Lælia tenebrosa, Cattleya Mendeli, Miltonia vexillaria leucoglossa, and Cypripediums Parishi and bellatum from Mr. Howes.

Roses were the main feature in the cut flower division, Messrs. F. Cant & Co., Colchester, beating Mr. G. Mount, Canterbury, in the classes for forty-eight distinct, and for twelve Teas or Noisettes. The N.R.S. bronze medals were awarded to Duchesse de Morny and Alfred Colomb. Mr. C. J. Salter, gardener to T. B. Haywood, Esq., Reigate, and Mr. Harris, gardener to E. M. Bethune, Esq., Horsham, were the most successful competitors among amateurs. Mr. G. Elwes, gardener to Major F. Luteridge, was the chief winner in the local division.

For herbaceous cut flowers Mr. H. Ware, gardener to Rev. J. Tillard, Penshurst, was ahead; Mr. T. Portnell, gardener to Sir A. Lamb, Bart., Battle, winning for a collection of stove and greenhouse cut flowers. Mr. F. Webber, Tonbridge, was first for a wreath, for sprays and buttonholes. Mr. S. Cooke, gardener to D. B. Crawshay, Esq., Sevenoaks, winning for a wedding bouquet, for three pieces, and for one piece of table decoration.

For three bunches of Black Hamburgh Grapes, Mr. C. Earl, gardener to O. E. d'Avigdor Goldsmid, Esq., Tonbridge, was well ahead; Mr. Laker beating him for three of any other black with Gros Maroc, and for three of Muscat of Alexandria. First prize for Nectarines was awarded to Mr. C. Harris for Elruge; to Mr. Allen for Peach Bellegarde; and to Mr. Carter for Melon Little Heath. A good collection of nine varieties came from Mr. C. Earl, who staged an almost perfect exhibit.

Non-competitive exhibits were good and in great numbers, but special mention may be made of Messrs. Charlton Bros'. grand herbaceous cut flowers.

HITCHIN.—July 7th.

On Wednesday last the summer exhibition of this Society was held in the grounds of the Priory, by kind permission of Mr. F. Delme Radcliffe. There was a large company present, especially in the evening when the three large tents were quite filled, and it was somewhat difficult for spectators to view the exhibits. The show of Roses was large, the blooms looked magnificent, and it was by far the best show of the last three years. No doubt this is owing to the weather having been more suitable for the flowering season. More superb blooms need not be wished for than those staged by Messrs. Prince (Oxford), Paul & Son, Burrell & Co., Harkness & Son, E. B. Lindsell, Esq., Rev. W. H. Jackson, and Mr. G. Moules. As time goes on, says a provincial contemporary, these growers run each other closer and closer for honours, and no doubt this Society, which originated in the Hitchin Rose Society, has been the means of stimulating to a very large degree the cultivation of the Rose in this neighbourhood, as specimens are now exhibited by amateurs and cottagers which a few years ago would not have been thought of.

The groups were very nicely arranged, and the first prize was deservedly awarded to Mr. W. Spencer, Codicote Lodge. The table decorations were remarkably pretty; there were eleven competitors, and Miss E. Logsdon was awarded first prize for a very delicate arrangement, and Mrs. W. Hill gained a second, Miss V. Shillitoe securing a third. The perennial and bulbous-rooted plants were very numerous, and added greatly to the appearance of the Show. The outdoor fruit was good considering the changeable season we have lately experienced, and the baskets of vegetables were excellent. Great credit is due to the Committee and Secretary for the excellent manner in which the arrangements were carried out. The following is a list of the prizes awarded in a few of the classes:—

In the open to all England class for forty-eight Roses, distinct.—First, Mr. E. B. Lindsell, Bearton, Hitchin. Second, Messrs. Harkness and Son. Third, Messrs. Burrell & Co. Fourth, Messrs. Paul & Son. Twelve Roses, two varieties.—First, Mr. E. B. Lindsell. Second, Messrs. Harkness & Son. Third, Messrs. Paul & Son. For eighteen Roses, Teas or Noisettes, distinct.—First, Mr. G. Prince, Oxford. Second, Messrs. Harkness & Son. Third, Messrs. Burrell & Co.

Several classes were open to members of the Society only. For twenty-four Roses, distinct, first Mr. E. B. Lindsell; while for eighteen, Rev. W. H. Jackson, Stagsden, was to the front. Twelve Teas or Noisettes.—First, Mr. E. B. Lindsell. Second, Rev. W. H. Jackson. Third, Mr. S. S. Berger, Bragbury End. Twelve distinct.—First, Mr. G. Moules, Hitchin. Second, Mr. W. O. Times, Hitchen. Third, Mr. W. Kingston, Bedford. Six Teas or Noisettes.—First, Mr. W. Kingston. Second, Mr. J. T. Hunt. Third, Mr. W. O. Times. Six distinct.—First and silver cup, Mrs. E. A. Moulden, Bandra House, Stevenage. Second, Mr. J. T. Hunt, Hitchin. Third, equal, Miss Alice Lucas and Mr. W. T. Lucas. Six single trusses of any Hybrid Perpetual.—First, Mr. E. B. Lindsell. Second, Mr. S. S. Berger. Third, Rev. W. H. Jackson. Six Teas or Noisettes.—First, Rev. W. H. Jackson. Second, Mr. E. B. Lindsell. Third, W. Kingston, Bedford. Six distinct single trusses.—First, Mrs. E. A. Moulden. Second, Mr. W. Furr. Third, Mr. J. Pollard, Highdown.

The bronze medal for best H.P. in the show was awarded to Mr. E. B. Lindsell for a fine bloom of Alfred Colomb. A bronze medal for best Tea or Noisette was awarded to the Rev. W. H. Jackson, Stagsden, for a splendid bloom of Comtesse de Nadaillac.

WOODBRIDGE.—July 8th.

Woodbridge is a clean, substantial, prosperous-looking Suffolk town of some 4000 inhabitants. As Mr. Mackellar, the Prince of Wales' gardener at Sandringham, observed on the occasion of his first visit as a Judge, it has a live-and-let-live look about it that it is pleasant to see; and a gayer and brighter town could not have been seen in all England on the day of the forty-sixth annual exhibition. The streets were canopied by flags and streamers, in which it would almost seem as if every householder had been anxious to share. The bells in the magnificent tower of St. Mary's church commenced the jubilation soon after sunrise, and continued at intervals till the full and splendid band of the Scots Guards arrived in the beautiful Abbey grounds, again kindly placed at the disposal of the Committee by Captain R. J. Carthew. The site is an

ideal one for a flower show on a fine day—a sort of grassy dell surrounded by luxuriant trees, suggestive of the famous Shrewsbury site in miniatnre, the visitors reminding also of the Shrewsbury enthusiasm—as fine a company as could be imagined in a town of much larger dimensions. The enterprising Great Eastern Railway provided special trains, with the result that the show grounds presented a highly animated appearance.

Only the general character of the Show will be indicated, as seeing that the schedule contained no less than 176 classes, a detailed report is out of the question. The products were arranged in five large marquees, one being devoted to plants, a second to Roses and cut flowers, a third to floral decorations mainly, a fourth to fruit, and a fifth to vegetables. The plant tent was better furnished than it has ever been before. Tuberous Begonias made a splendid display, both as arranged in groups with Ferns and in the form of specimen plants, and the prizewinners, General Farren, Mr. J. A. Burness, the Rev. T. Hanscroft, Mr. W. H. Crisp, Mr. T. Grimwood, and Major Howey, with their respective gardeners, are deserving of warm congratulations on the high excellence of their products. In Major Howey's group (gardener, Mr. W. Sowman), from Melton Grange, a double salmon pink variety, was very striking, and named Melton Beauty. Groups of Gloxinias with Ferns were also very charming as arranged by the gardeners to Miss Walford, Mr. A. Hayward, and Mr. Webster Adams. Fuchsias also were attractively prominent, relieved by remarkably fine specimens of exotic Ferns

The Rose tent contained many beautiful stands of blooms, also a fine group of decorative Roses arranged by Messrs. F. Cant & Co. In this group a new climbing variety with large semi-double rich maroon flowers may be expected to have a great future before it. Mr. "W. R. Raillem" obliges with the following notes on the competitive section :—In the trade classes Messrs. Frank Cant & Co. were first for the 25-guinea challenge cup of twenty-four Roses, this being the second time they have won it. Horace Vernet, Niphetos, and Marchioness of Dufferin were among the best examples, and the new Rose, Mrs. Frank Cant, was fairly well shown. Mr. B. R. Cant was a good second with a very fine bloom of Le Havre and a capital Horace Vernet. Messrs. D. Prior and Son were third with a splendid Maréchal Niel, rather dwarfing the quality of the other blooms. With thirty-six blooms Mr. B. R. Cant was first, the sheen of old gold on a rather damaged bloom of Luciole being conspicuous in the centre. Messrs. Frank Cant & Co. were second, but first in the next class of twelve Teas with Bridesmaid and Catherine Mermet (a good deal alike) in fine condition. Messrs. D. Prior & Son were second, Madame Cusin being their best bloom, and Mr. B. R. Cant third. In trebles Mr. Frank Cant was again first, a good triplet of Captain Hayward being in his stand ; Mr. B. R. Cant second, and Messrs. D. Prior & Son, who, perhaps from a misconception, showed nothing but Teas, third.

In the amateur classes Rev. J. H. Pemberton won the challenge cup for twenty-four for the second time in succession, but the blooms were hardly up to his usual standard. He took the medal with Marshal P. Wilder, but it was not an extra good bloom. Mr. Orpen was second, showing some splendid Teas, only twelve of which were allowed by the schedule. Maman Cochet, a slightly damaged bloom, took the medal, and he had also all the other well-known members of the Mermet family, Mermet herself, Bridesmaid, The Bride, and Muriel Grahame. He was also first in twelve Teas, but these were not so good. Mr. Foster-Melliar was second, showing Maman Cochet and Madame Cusin well. Mr. Orpen was also first in six H.P.'s of a sort with S. M. Rodocanachi, and with six Teas of a sort with Maman Cochet, and in six trebles, all of very fine Teas. He had practically no opposition in these classes. In twelve Roses Mr. Parsons showed a good stand, two of his blooms, Horace Vernet and Duchess of Bedford, being taken into competition for the medal H.P.

The fruit tent contained wonderful collections of the smaller kinds, such as Currants, Gooseberries, Raspberries, all in fine form ; also a grand display of Strawberries, and out of the whole great display Gunton Park was adjudged the chief prize for flavour. With a collection of fruit Mr. W. Messenger, gardener to C. H. Berners, Esq., Woolverstone Park, won the premier prize with good Black Hamburgh and Buckland Sweetwater Grapes, fine Peaches, Nectarines, Waterloo Strawberries, Cherries, Figs, and a Melon. Mr. Rogers, gardener to Lord Rendlesham, and Mr. Andrews, gardener to the Hon. W. Lowther, followed in close order with excellent produce. They were also successful in many other classes.

The competition for the prizes offered for collections of vegetables by Messrs. Sutton & Sons, Carter & Co., and Daniels Bros. were great and good, the results being creditable to all concerned.

The marquee devoted to floral decorations was a source of great attraction. More than a dozen tables were placed in competition, and it was no small triumph for Mrs. Orpen, West Bergholt, to have won first honours in the open class. The dainty Garland Rose was employed with much taste in association with Ma Capucine and Madame C. Guinnoiseau, relieved with light touches of Gypsophila and Fern. In the local class Miss W. Carter was the premier exhibitor with a bright and light association of Iceland Poppies and Ferns. There was a great display of Sweet Peas, baskets of Roses, and other ornaments. Mr. R. C. Notcutt was the chief prizetaker with hardy border flowers, and Messrs. R Wallace & Co. had a charming display of choice Liliums and Calochorti.

From whatever point of view regarded the show was a great success, thanks to an efficient Committee, good supporters, and the genial and zealous Secretary, Mr. John Andrews.

HARROW.—July 8th.

On Thursday last, in the grounds of Julian Hill, the Harrow Horticultural Society held its annual exhibition. Though there were open classes and others subject to the customary restrictions the display was not a very great success ; indeed, had it not been for the superb Roses staged by C. J. Grahame, Esq., and Messrs. B. R. Cant, G. Prince, J. Veitch & Sons, Ltd., F. Cant & Co., and W. Paul & Son, it would have been very poor. Hardy flowers were splendidly shown by Mr. E. Beckett, and table decorations by ladies were charming. The terrific hailstorm of some days ago cut a considerable amount of produce to shreds and entirely prevented many growers from competing.

As has been said the Roses shown were of magnificent quality, and make by far the finest feature of the exhibition. The chief class was for thirty-six distinct single trusses, the premier award being taken by Mr. B. R. Cant, Colchester, whose exhibit was composed of even, well-coloured blooms. The varieties represented were Her Majesty, Gustave Piganeau, Marchioness of Londonderry, Fisher Holmes, Marchioness of Dufferin, Marquise de Litta, Mrs. John Laing, Ulrich Brunner, Helen Keller, Comtesse d'Oxford, Mrs. R. G. Sharman Crawford, Marie Baumann, Duchesse de Morny, Madame de Watteville, A. K. Williams, White Lady, Mons. E. Y. Teas, Merveille de Lyon, Jean Soupert, Lady Mary Fitzwilliam, Star of Waltham, Mrs. Paul, Dupuy Jamain, Madame Eugène Verdier, Golden Gate, Horace Vernet, Kaiserin Augusta Victoria, Xavier Olibo, Marchioness of Downshire, Comte de Raimbaud, Ethel Brownlow, Capt. Hayward, Madame Cusin, Le Havre, The Bride, and Charles Lefebvre. Messrs. F. Cant & Co., Colchester, were second, their best varieties being Comte de Raimbaud, Ethel Brownlow, Kaiserin Augusta Victoria, Maman Cochet, Fisher Holmes, Jeanie Dickson, and Madame de Watteville. Mr. Geo. Prince, Oxford, was third.

The only other class open to all comers was for twelve Teas or Noisettes, distinct varieties, one truss of each. Mr. Geo. Prince secured the first prize, followed exceedingly closely by C. J. Grahame, Esq, Leatherhead. The winner staged Comtesse de Nadaillac (superb), Souvenir de S. A. Prince, Madame Cusin, Innocente Pirola, Catherine Mermet, Maman Cochet, The Bride, Ernest Metz, Cornelia Koch, Francisca Kruger, Alba Rosea, and Princess of Wales, the last two being weak, and detracting materially from the quality of the stand. Mr. Grahame's examples of Maman Cochet, Ethel Brownlow, and Muriel Grahame were superb, the first named being perfect. The third position was assigned to Mr. B. R. Cant.

There was also a class for twenty-four distinct single trusses, open to all amateur growers, and here C. J. Grahame, Esq., showed his strength in a most decisive manner. In the whole twenty-four there was scarcely one really weak flower, though there were several as good as any we have seen this season. The varieties included Gustave Piganeau, Her Majesty, Charles Lefebvre, Mrs. R. G. Sharman Crawford, Horace Vernet (quite perfect), Susanne Marie Rodocanachi, A. K. Williams, Marchioness of Londonderry, Maman Cochet (superb), Le Havre, Mrs. John Laing, Maréchal Niel, François Michelon, Marchioness of Dufferin, Ulrich Brunner, Comtesse de Nadaillac, Dupuy Jamain, Catherine Mermet, Alfred Colomb, Lady Sheffield, Louis Van Houtte, Madame Cusin, Victor Hugo, and Star of Waltham. R. E. West, Esq., Reigate, was second ; and J. Bateman, Esq., Highgate, third.

Besides the Roses in the section to which we have just alluded, there were other classes of minor importance, but no specimens of special merit were staged therein. Of non-competitive exhibits of Roses there were two only, one from Messrs. J. Veitch & Sons, Ltd., Chelsea, and the other from Messrs. W. Paul & Son, Waltham Cross. Both of these firms sent some splendid Roses, and in so doing added considerably to the interest and beauty of the show. Messrs. Veitch showed amongst many others Susanne Marie Rodocanachi, Etienne Levet, Bridesmaid, Comtesse de Nadaillac, Alfred Colomb, Duke of Wellington, Madame Cusin, Francisa Kruger, Catherine Mermet, Madame Lambard, and Dr. Andry. Messrs. Paul staged Her Majesty, Pride of Waltham, Merveille de Lyon, Mrs. W. J. Grant, Viscountess Folkestone, Grand Mogul, La France of '89, Marquise de Litta, and the beautiful Waltham Standard.

Mr. E. Beckett, gardener to Lord Aldenham, Aldenham House, Elstree, was an easy first in the class for twenty-four bunches of hardy flowers, distinct, each bunch to be shown in a separate vase. The first prize took the form of a silver cup, presented by H. W. Bryans, Esq., the Hon. Treasurer of the Society. The exhibit included amongst others Galega officinalis, Potentilla Mrs. W. Rollinson, Catananche cœrulea, Delphinium exaltatum, Phlox Le Soleil, and Chrysogonum virginianum. A. Kingswell, Esq., Harrow Weald, was second.

In the class for a group of flowering and foliage plants, arranged for effect in a space not exceeding 50 square feet, Mr. W. Smith, gardener to S. Gardner, Esq., was first with a somewhat heavy and dull exhibit of Ferns, Caladiums, Palms, Gloxinias and Begonias. This would have looked much better had the plants not been so packed together. Mr. E. Hawkins, gardener to J. M. Stuart, Esq., was second ; Mr. W. Elvey, gardener to R. Bosworth, Esq., third. Messrs. W. Cuthush & Sons, Highgate, sent a fine exhibit of Hydrangeas, Carnations, Liliums, and Begonias, not for competition, while Messrs. J. Laing & Sons, Forest Hill, sent superb Begonias.

In the several classes for vegetables, fruits, and plants, the competition was in no case particularly keen, and there was nothing staged that called for special mention here. Tables and vases of flowers staged by ladies showed much beauty and taste, but no notable originality. Several were completely spoiled by careless arrangement, whilst others were militated against by the use of paper and ribbons.

LEEDS.—July 7th, 8th, and 9th.

For ten years previous to this Jubilee year Leeds has not had the privilege of a summer flower show. This statement will naturally create inquiry why a city of the wealth of this great commercial centre should hold this anomalous position amongst other places of similar and even less importance horticulturally. In former times this much to be deplored state of matters was in no way due to the need of public spirit of the "good old town." At any time a hint in this direction would be considered a reproach amounting to an insult by its people, who, by the sheer force of their public spirit have lifted their town into the dignity of a city of such importance as to confer the title of Lord Mayor on its chief magistrate.

The times were in Leeds when first-class exhibitions were annually provided, but unfortunately the most persistent ill luck year after year in shape of rain and storm dogged the efforts of as plucky management as ever attempted to win success by deserving it. Year by year the weather proved so consistently bad that "Leeds show weather" became the tritest of proverbs, and as regularly the Committee had to fall back upon its supporters for money to carry on the war against the elements, and, as it eventually proved, a war with fate itself. The exhibitions, under the management of the old Committee having ceased as the years went by, those interested in the advance of horticulture have felt at a decided disadvantage, and the question of resuscitating the Show has often been discussed; but the old management have naturally fought shy of the matter, and as the difficulties of a reorganisation rested in getting together a body of business men not only possessed of the necessary qualifications to organise a show worthy of the city, but also having such confidence in each other to promote unity of effort as to deserve success if the weather were favourable, or on the other hand to stand back to back and accept the onus of failure.

The new Committee has had a somewhat mixed experience in the way of encouragement, accompanied by great difficulties and prejudices to combat. For the manner in which they have met and overcome them they fully deserve the thanks of their fellow citizens. By reason of the blank of ten years it would be difficult to estimate the loss to the neighbourhood from a horticulturist's point of view; but in the late treat provided by the Flower Show Committee, Leeds people should at least realise that by the Committee's exertions the reproach of neglecting their duty to the important art of horticulture has been removed, and their confidence and support be awarded to them as matter of duty, in the interest of all concerned.

The recent wholesale destruction of exhibits by the storm which entirely wrecked the York Show no doubt had a marked effect both on the quality and quantity of exhibits at Leeds. In many cases, but for their destruction, many would have found their way to Leeds, whilst the continuous boisterous weather had a deterrent effect on others for fear of the same fate of York overtaking their exhibits. The leading feature at Leeds undoubtedly was the open class groups of miscellaneous plants arranged for effect, occupying space not exceeding 250 square feet. Mr. J. S. Sharp, Valley Nurseries, Almondbury, secured the first prize of £15. The excellent colouring and free growth of the Crotons, added to the fact that the flowering plants generally were fresh and well timed, were strikingly evident, whilst the important features of the group were kept sufficiently low to bring them with the line of sight from any point, abundant scope for variety of detail and pleasing variation of the under surface were maintained. In fact, the whole arrangement was in excellent taste, including a more natural background than was shown in the other collections. Mr. R. Simpson secured the second prize of £10 with a very high group, the background being somewhat stiff and formal, otherwise the arrangement was exceedingly good, the Crotons being highly effective; and Mr. W. Townsend, gardener to E. Beckitt Faber, Esq., J.P., Belvedere, Harrogate, the third; Mr. A. Taylor, Allerton House, was fourth.

In the class for six stove and greenhouse plants the only prize awarded fell to Mr. J. Sunley, Monkfuston Nurseries. The prizes for six ornamental and fine-foliage plants fell to Messrs. Simpson, Townshend, and Sharp in the order named. In this class the Judges awarded to Mr. Sunley a special prize for a magnificent plant of Cycas revoluta. For three Crotons, distinct, Messrs. Sharp, Townshend, and Simpson and Sons won in the order named.

The classes for exotic Ferns were very good. The first prize for six distinct varieties was won by J. Rhodes, Esq., Potternewton House (gardener, Mr. R. Mason); Mrs. Tetley, Weetwood (gardener, Mr. J. Eastwood), second; and Mr. Taylor third. In the class for three Messrs. Rhodes, Kitchin, and Mrs. Tetley were the prizewinners. The Orchids were not numerous, but comprised some fine specimens from the collection of T. R. Jessop, Esq, J.P., Roundhay Mount (gardener, Mr. T. Tyson), who won the first prize for six plants, including Cattleya Mossiæ, C. Mendeli, Oncidium macranthum, and a fine plant of Saccolabium guttatum, carrying thirteen beautiful spikes of well-marked blooms. Messrs. J. W. Moore, Rawdon, and J. Sunley secured the remaining prizes.

Roses in pots were moderate in quality; the only prize awarded fell to Mr. H. Pybus, Moore Monkton, Leeds. Table plants were good, but did not include anything new or specially striking, the prizes falling to Messrs. Townshend and Sharp for specimens in 6-inch pots, whilst Mr. J. W. H. White, Mr. M. Kitchin, and Mr. Eastwood won the prizes limited to within seven miles of Leeds.

In the cut flower classes, whilst the quality was generally good, there was abundant room for more competition. The most noticeable were the stand of twelve Tea-scented Roses shown by D. & W. Croll of Dundee, and stands for twelve bunches of stove and greenhouse cut flowers (open). The winners were Mr. Tyson and Sir J. Pease, M.P., Hutton Hall (gardener, Mr. McIndoe). Messrs. Shaw Bros. of the Covered Market, Leeds, showed baskets of flowers and bridal bouquets, winning first prizes in the several classes; Mr. A. Taylor being second.

The fruit classes were highly meritorious. The first prize for ten kinds was won by Mr. J. Edmonds, Bestwood Lodge, Arnold, Notts; the second prize went to Mr. McIndoe, and the third to the Earl of Harrington, Elvaston Castle (gardener, Mr. Goodacre). In the class for three bunches of Black Hamburgh Grapes Lady Beaumont, Carlton Towers (gardener, Mr. W. Nichols), was first with well-finished bunches; W. Sheepshank, Esq., Ripley (gardener, Mr. A. Large); Mrs. Braithwaite, Throstle Nest, Horsforth (gardener, Mr J. W. Pybus). For three bunches of white Grapes Mr. Nichols was again deservedly placed first with three bunches of finely finished Buckland Sweetwater; second, Mr. McIndoe. The first prize for a tray of vegetables of eight varieties was won by Mr. Nicholls; second, Mr. McIndoe; third, Mr. A. Radcliffe, Elland.

NEW BRIGHTON.—July 10th.

Known as a health-giving resort rather than for its prominence as a floral centre, this seaside rendezvous on the banks of the Mersey is noted annually for its excellent Rose show, the proceeds being given to the Wallasey Cottage Hospital, and so instead of partaking of the usual orthodox system of shows it resolves itself into more of a large garden party. And what a delightful garden is Dr. Bell's, the ever popular and esteemed President! Woodland walks where one can listen to the music without fear of interruption, and watch the players at lawn tennis striving for the victory on the sward in front. The day was perfect, and the ladies in their bright colours left nothing wanting in their efforts to try to make the day a success. T. R. Bulley, Esq., J.P., the courteous Secretary, had made excellent arrangements for exhibitors.

Many of the old growers were no doubt at Manchester, but their absence was more than compensated for by the splendid array brought together by the Irish firm of Alex. Dickson & Sons, Newtownards, Co. Down. They were something to remember by reason of the many new seedlings, and the perfect condition of the older of this firm's raising. A few of the newer ones must be reserved for a later article, but one named "Ulster," an ideal light Rose of fine form and great substance, will almost surpass anything yet seen by the best of our growers, and the New Brighton people are greatly indebted to Messrs. Alex. Dickson and Sons for such a fine display. Dicksons of Chester, too, were in capital form, their flowers being extremely good.

For forty-eight, distinct, single blooms, Messrs. Alex. Dickson and Sons, Royal Nurseries, Co. Down, were well first with probably one of the finest stands this firm ever staged. The varieties were Caroline Testout, Mrs. Jowett, Countess of Caledon, Gustave Piganeau, Lady Mary Currie (seedling), Louis Van Houtte, La France, Abel Carrière, Mrs. J. Laing, Victor Hugo (grand in colour), Madame Eugène Verdier, Alfred Colomb, Marquis Litta, Miss Bessie Brown (handsome), Charles Lefebvre, Kaiserin Augusta Victoria, Star of Waltham, Marchioness of Londonderry (splendid), Horace Vernet, Lady Mary Fitzwilliam, Etienne Levet, Pink Seedling, Earl of Dufferin (charming), Souvenir d'Elise, Souvenir de S. A. Prince, Madame Cusin, The Bride, Exposition de Brie, Rosamaine, Alix Huguier, Beauty of Waltham, Avoca (new seedling Tea), Maman Cochet, Muriel Grahame, S. M. Rodocanachi, Marie Van Houtte, Countess of Rosebery, Robert Duncan (new), Dr. Andry, Ulster (new seedling H.P., and quite the gem of the Show), Devienne Lamy, Her Majesty, Marie Rady, Mrs. W. J. Grant (splendid), Niphetos, Marie Verdier, Lady Moyra Beauclerk, and François Michelon. The second prize fell to Dicksons, Ltd., Chester, with a fine stand of more than passing interest. Most noticeable were Her Majesty, Mdlle. Eugène Verdier, Captain Hayward, Fisher Holmes, Pierre Notting (very fine), Susanne Marie Rodocanachi, Comtesse de Serenye, White Lady, and Paul Neron.

For twenty-four varieties, three trusses of each, the Irish firm was the only exhibitor, but with a faultless stand that would have won a position at any show. Mrs. W. J. Grant, Marchioness of Londonderry, Alfred Colomb, Caroline Testout, Horace Vernet, Ulster, Marie Baumann, Alice Lindsell, Earl of Dufferin, Lady Moyra Beauclerk, Jeannie Dickson, Dr. Andry, Bessie Brown, Gustave Piganeau, Maman Cochet, Dupuy Jamain, Alice Grahame, Louis Van Houtte, Countess of Caledon, Kaiserin Augusta Victoria, La France, A. K. Williams, Souvenir de S. A. Prince, and Heinrich Schultheis.

For twelve blooms one colour Alex. Dicksons and Dicksons, Ltd., were awarded equal first, the former with Marchioness of Londonderry and the latter with Mrs. R. G. Sharman Crawford. The former were the only exhibitors of twelve Teas and Noisettes, but again the same excellence was maintained, Miss Bessie Brown, Comtesse de Nadaillac, Souvenir d'Elise Vardon, Ethel Brownlow, Maman Cochet, Madame Hoste, Madame de Watteville, Muriel Grahame, Niphetos, Madame Cusin, Souvenir de S. A. Prince, and Catherine Mermet being the varieties.

Amongst amateurs the best prize was for twenty-four distinct, the N.R.S.'s gold medal accompanying it. Here, as in all the other classes, the enthusiastic amateur H. V. Machin, Esq., Worksop, was a capital first, the varieties being Ulrich Brunner, Marchioness of Londonderry, Xavier Olibo, François Michelon, Earl Dufferin, Caroline Testout (superb), Gustave Piganeau, Mrs. J. Laing, Mrs. R. G. S. Crawford, Duke of Teck, S. M. Rodocanachi, Horace Vernet, Her Majesty (grand), A. K. Williams, Eugène Verdier, Dupuy Jamain, Louis Van Houtte, Merveille de Lyon, Charles Lefebvre, Margaret Dickson, Alfred Colomb,

Mrs. W. J. Grant, Victor Hugo, and Madame Gabriel Luizet. A capital second was staged by Wm. Stubbs, Esq., the best being Marchioness of Londonderry, Ulrich Brunner, Mrs. J. Laing, Her Majesty, Emilie Hausburg, and Général Jacqueminot. Mr. Machin won with eighteen distinct, Ulrich Brunner, Her Majesty, Maurice Bernardin, Louis Van Houtte, S. M. Rodocanachi, and Etienne Levet being superb. H. G. Roberts, Esq., was an excellent second.

Mr. Machin again scored easily for six light varieties with Mrs. J. Laing, and six dark with handsome Ulrich Brunner; also for twelve Teas and Noisettes, the silver medal of the N.R.S. being awarded. Very choice were Catherine Mermet, Jeanne Ducher, and Innocente Pirola. H. J. Roberts, Esq., had a nice stand for second place. T. R. Bulley, Esq., staged well for twelve distinct, fine being Caroline Testout, Ulrich Brunner, Marchioness of Londonderry, Mrs. J. Laing, Earl of Dufferin, Margaret Dickson. Dr. Bell second. Alex. Dickson and Sons were granted a first-class certificate for six new Roses with Lady Moyra Beauclerk. A. J. Mead, Esq., won the N.R.S. bronze medal and prize for six varieties. T. R. Bulley, Esq., had a charming stand of twenty-four distinct hardy perennials. Amongst the number of good things noted being Liliums giganteum and testaceum, and Dianthus Atkinsoni. Dr. Bell was first for twelve varieties, and A. J. Mead, Esq., for six; Mr. Jowett following in each class.

The two Dicksons had also splendid stands, the Belfast firm staging eighty bunches of new and rare types, and the Chester firm a lesser number, but all in the same good condition as the former. Hinton Spalding, Esq., had twelve choice Carnations. Mr. C. A. Young, Floral Nursery, West Derby, Liverpool, had a stand of one hundred flowers of the choicest and best Carnations and Picotees, the Malmaisons, for which he is celebrated, being to the fore. It was a grand exhibit, and deservedly admired by all present.

BATH.—JULY 10TH.

THE Rose Show was held in the Sydney Gardens under blue skies and bright sunshine. Of the Show itself, says the "Bath Herald," very little room for adverse criticism can be found, the high character of the exhibits being fairly well maintained, while the prize fund offered had sufficient attractions to guarantee a good average show. The past season has probably been the most favourable for Rose growing experienced for some five or six years, and its effect was wonderfully apparent in the excellent condition of the exhibits and their general brightness of colour. This year the Committee has exhibited a commendable spirit of enterprise, and several attractive features appear which are novel to a Rose show. Classes have been introduced exclusively for ladies, and the interesting display of decorated bicycles and tastefully laid out dinner-tables, which lent such attractions, must sufficiently compensate the Committee for making the experiment. The inclusion of such a novelty for a Rose show as a musical bicycle ride also aroused additional interest in the fixture, and in every respect the Committee is to be congratulated upon the departure from the old-time régime. Messrs. Cooling & Sons scored a big success in the nurserymen's department, carrying off the first awards in both the premier Rose classes, while in the amateurs' section similar distinction was gained by the Rev. J. H. Pemberton, Mr. S. P. Budd being placed second in the leading class. To Messrs. Cooling & Sons was also awarded the silver medal of the National Rose Society for the best Hybrid Perpetual Rose in the Show for Susanne Marie Rodocanachi, the other medal given by the National Society being secured by Mr. J. Mattock of Oxford for The Bride. Begonias made a charming display. We subjoin the prize-winners in a few of the principal Rose classes.

The chief Rose class was for seventy-two distinct varieties, single trusses.—First, Messrs. G. Cooling & Sons. Second, Messrs. Paul and Son. For thirty-six, three trusses of each.—Messrs. George Cooling and Sons received the premier award, while for eighteen Mr. J. Mattock was first, Mr. G. Mount second, Mr. C. Turner third. In the class for thirty-six single trusses.—First, Mr. J. Mattock. Second, Mr. G. Monnt. Third, Mr. S. Tresedar; and for eighteen Teas or Noisettes, distinct varieties, single trusses.—First, J. Mattock. Second, S. Tresedar. Third, G. Mount.

In the amateurs' division the first prize for thirty-six distinct varieties, single trusses, went to Rev. J. H. Pemberton, and the second to Mr. S. P. Budd. For twenty-four distinct varieties, single trusses, the prize-winners were Messrs. T. Hobbs, J. Parker, and Rev. Powley in the order named. For twelve.—First, Rev. R. Powley. Second, T. Hobbs. Third, J. Parker. While for twelve, three trusses of each, T. Hobbs was first, Rev. R. Powley second, and J. Smith third.

In the class for eighteen Teas and Noisettes, distinct varieties, single trusses—First, A. Hill Gray. Second, S. P. Budd. For twelve—First, R. Foley Hobbs. Second, J. Parker. Third, J. Hinton. Six ditto, three trusses of each—First, A. Hill Gray. Second, Rev. R. Powley. Third, J. Parker. The most decorative arrangement of Roses, space not exceeding 10 feet long by 4 feet wide (small plants of Palms, Ferns, or Mosses in pots may be used in this group)—First, Messrs. George Cooling & Sons. Second, Mr. George Garraway.

THE WEEPING OF VINES.—After the spring pruning in the vineyards, water is seen trickling down the stems, and in France this is poetically called the "weeping of the Vine." Prof. Cornu, a botanist, has recently studied this phenomenon, and he says it is due to the abundant absorption of water by the roots of the Vine in spring time. The water is forced through all the branches and stems to their very tips, and where they are cut by the pruner it oozes out like teardrops.

DWARF PHILADELPHUS.

THE tall-growing species and varieties of Philadelphus are well known to most people. The dwarf ones, however, are by no means so universally grown. As far as beauty and use go, they are quite as pretty, and, if anything, more useful than their taller growing relatives, as they can be grown in a number of places where tall ones would be out of place, and a good constitutioned, quick-growing, and free-flowering shrub is wanted. The dwarf race of Philadelphus has been brought about by the dwarf species P. microphyllus being crossed with P. coronarius, Messrs. Lemoine of Nancy being the principal workers in this direction.

P. microphyllus grows to a height of about 2½ feet when mature, and forms a dense bush made up of slender, upright branches. The leaves are about half an inch long covered (especially on the under surface) with silvery down. The flowers are half an inch across, and freely produced during June.

P. Lemoinei is a hybrid, one of the offspring of the foregoing parents. It may be grown to a height of 3 feet, but can be kept for several years at little more than half that. The branches are thin and pendent, the leaves ovate with an acuminate apex, 2 inches long, the upper half slightly serrate, with a few minute hairs on both surfaces. The flowers are pure white, three-quarters to 1 inch across, and very sweetly scented. The flowers are produced along the whole of the past summer's growth. A variety of this, known as "P. Lemoinei var. erectus," is similar to the former in all respects save in its more upright habit; if anything it shows its flowers off to the better advantage of the two.

P. Gerbe de Neige is much like the former, but the flowers and leaves are larger. P. Boule d'Argent is very similar in habit to P. Lemoinei, but the flowers are double, and inclined to cream rather than white. The golden-leaved variety of the common Philadelphus, P. coronarius var. foliis aureis, never grows very tall. It forms a thick bush, which by pruning can be kept from 1½ to 2 feet high. The leaves are of a beautiful golden colour, which makes the plant worth growing for that cause alone.

The cultivation of these plants is simple. Given almost any kind of soil with top-dressings of manure occasionally, they are almost sure to thrive. After flowering in the P. Lemoinei section the shoots should be cut back to where young growths are springing from the base. By keeping the old wood cut out more room is left for long new branches to be made, the consequence of which is a greater wealth of blossoms. People who intend planting shrubs, especially those whose shrubbery room is restricted, cannot do better than include these in their selection. —W. D.

THE CALIFORNIA ORCHARDS.

THE fruit crop of California is again below the average, owing to frosts in some districts, and to hot dry winds in others. A few valleys report larger crops than usual, and single orchards are in some cases well laden, though surrounded by others that have no fruit. The following notes are from personal observation and the reports of correspondents:—

Almonds are much below the average, but in a few districts show a large crop. Apricots are generally excellent, except in Sacramento, Kern, and parts of Ventura counties. Cherries are below the average, particularly the large, light-coloured varieties, such as Royal Ann. Peaches are difficult to report upon, because districts vary so greatly, but the crop is thought to be only an average one. Pears, Plums, and Prunes promise a fair crop in a few places, but seem to be short in many orchards. Los Gatos, San Benito, and Solano districts report the Prune crop as from one-third to one-half of the average season. The Pears also have fallen badly. In fact it is too early to determine exactly the prospects for either Pears or Prunes. Apples seem to be in good condition. Walnuts are up to the average. The Grape crop, so far as reported, is better than usual.

In most cases under my own observations, more injury was done by the failure of late rains and by the hot days of early April than by frosts. But in the parts of the State subject to frosts there has been much injury to deciduous fruit trees from "sour sap," which, as Professor Woodworth of the University of California recently explained, consists in the fermentation of the sap of the plant by apparently the same organisms that cause the souring of milk. Root sour sap occurs after very wet winters, in badly drained soil, and the smaller roots rot away. Sour sap in the trunk and branches of trees occurs when late frosts, after warm days, rupture the growing cells, so that decay organisms find entrance. One orchard association has reported the loss of a thousand large trees from this sour sap.

Taking a general view of the fruit industry of California, as should be occasionally done so as to prevent people from making unprofitable investments, the outlook is not very encouraging except in a few limited directions. Of course, reports of large profits made by persons engaged in fruit growing still continue, but at present they should be believed only after careful judgment. The average orchardist has not made any money to speak of for three seasons past, and some of the leading men in the business have become bankrupt. Some orchards have been cut down and many have been regrafted. This is particularly true of Almonds, which have been grafted over to Prunes.

There is now a general feeling in California that the fruit industry ought not to have much, if any, expansion for several years to come. Perhaps one fruit grower in a hundred will find orchard extension

profitable, but nearly all will lessen their area and specialise their products.

The wiser residents regret to see sales of colony lands at high prices to non-residents for orchards which must be planned, planted, and cared for by agents or by those who sold the land. California offers many and great inducements to persons who are able to buy land, live on it, and begin work there, supporting themselves by plain, old-fashioned, mixed farming until they have learned how to specialise. And this kind of pioneering, of growing up with the country, appears needful to later contentment.

One colony in this State boasts that it has more than a hundred non-resident investors, most of whom will not see the land they own until it is covered with bearing Vines and trees. For five or six years they have paid for the planting and care, hoping to find their orchards and vineyards profitable. But such tracts, managed by syndicates and associations, have never been satisfactory, even from a financial standpoint, while the poor instalment-payers are without that homely attachment to trees that one has planted, and to gardens that one has created, which is really the only salvation. Thousands of acres of these alien and hireling orchards are likely to go back to pasture and Wheat fields.—CHAS. H. SHINE (in "Garden and Forest.")

LILIUM CONCOLOR.

A GRACEFUL plant is Lilium concolor when flowering in gardens where Lilies are prized. The flowers are of moderate size, the petals narrow and recurving, but the colour is a peculiarly bright orange red, and the whole appearance is light and elegant. Variations from seed are not uncommon, and they differ chiefly in the depth of the colouring on the prominence of the spots. One variety is noticeable for its soft tint, all clearly defined spots, a flower of which is reproduced in the accompanying woodcut (fig. 10). In some old works this Lily is referred to as a greenhouse plant, and in the early part of the present century it was so grown. Long since, however, it was proved to be hardy, and is now the occupant of many borders. It succeeds wherever the soil is not excessively heavy, cold, or waterlogged, but is also adapted for culture in pots.

THE YOUNG GARDENERS' DOMAIN.

PEACHES AND NECTARINES.

(*Continued from page* 35.)

WHEN the trees are in full growth the leading shoots may be stopped at the fourth large leaf if the allotted space is covered, if not the growths may extend to their full length. All sub-laterals on established trees should be stopped at the first joint.

Thinning the fruit is deferred too long in many if not most cases. Peaches and Nectarines generally set well if the blooms are protected in some way. As soon as can be seen, deformed fruits and a number of crowded fruits should at once be removed, leaving about double the quantity required for ripening till stoning commences. The crop required to ripen must then be decided upon, bearing in mind that large fruits of good varieties are always the best flavoured. Watering the trees must be attended to if the best results are expected, and if the borders are mulched early in the summer with strawy manure a great saving is gained. It is best to leave the soil loose around the trees for an inch deep, as the water soaks in better, and prevents the soil cracking.

Insects most commonly found on Peach trees are aphis and red spider. Both of these pests require early attention to prevent their increasing, or the result will be disastrous. Quassia extract and softsoap will destroy aphis of all kinds if applied in liquid form. As soon as the buds begin to swell or break into growth is the best time to grapple with spider or aphis. Choose a warm day, and when the sun is shining set the garden engine or syringe to work, following it up about three times a week, excepting when the trees are in flower, and not much trouble from these pests should occur. Syringing with clear water, late in the afternoon of hot days, until the fruits begin colouring is beneficial to the trees.

The following are good varieties for succession: *Peaches.*—Waterloo, Hale's Early, Rivers' Early York, Crimson Galande, Magdala, Royal George, Dymond, Bellegarde, Stirling Castle, Goshawk, Barrington, and Walburton Admirable. *Nectarines.*—Cardinal, Early Rivers, Lord Napier, Stanwick Elruge, Pine Apple, Dryden, Milton, and Spencer. —J. L. G.

THE MEANS AND MODES OF PROPAGATING PLANTS.

(*Continued from page* 12.)

PLANTS are broadly classified by the character and permanence of the stem, this being annual, biennial, or perennial. Thus in the annual the plant is raised from seed in the spring or the winter preceding the spring in which it appears above ground, the stem attaining its fullest development in summer when the blossom appears, and the seed is subsequently produced and ripened. When the seed is ripe the functions of the roots and stem are performed, and the plant dies to be reproduced from the seed that it has yielded. The various cereals, many vegetables, and all the flowers popularly termed annuals may be cited as examples of this class.

A biennial lives, as the term implies, for two years. The seed from which it is raised is sown in the spring, and during the first year of its existence the plant produces leaves, and in some cases develops a fleshy, tuberous, quasi root. In the second year, as spring is ripening into summer, the plant sends up a strong stout stalk, which blossoms and yields seed. As in the annual, when the seed is ripe the work of the root and stem is done, and the plant perishes. Parsley, the Carrot, the Parsnip, and Beetroot afford familiar examples of plants of this class.

Perennials differ from annuals or biennials in the length of their duration. They live more than two years, and in some cases for hundreds of years. Among such may be named ancient Oaks and forest trees in various parts of the world, the Vine at Hampton Court, and the still more wonderful Rose tree at Hildersheim in Germany. All perennials are not long-lived. They last a few years, some dying down to the ground and sending up fresh stems yearly, and others retaining their

FIG. 10.—LILIUM CONCOLOR.

branches and shedding their leaves in the autumn, or from time to time gradually and almost imperceptibly, as evergreens. But many show deterioration in every way as they advance in age, and ultimately perish or are rooted up to make room for plants of a similar kind in full strength and vigour.

Advantage has been taken of the varying character of perennial plants to classify them in accordance with their habit of growth and appearance. Thus plants whose stems are soft and succulent, and contain but little woody fibre, and die down to the roots annually to spring up again next year from buds formed at the base of the perished stems, are called herbaceous plants. The Lychnis, the Phloxes, some of the Delphiniums or Larkspurs, and Michaelmas Daisy are examples of herbaceous plants. Trees, on the contrary, whose stems are composed of hard woody fibre, are classified as ligneous plants. Shrubs are ligneous plants by reason of the hardness and toughness of their stems, although they differ widely in height and dimensions from trees properly so called, varying in altitude from about 2 feet to 20 feet. The stems of shrubs throw off an undergrowth at their base which develop into new stems in

time, and produce flowers. The Rose is an example of the smaller kinds of shrubs, the Laurustinus of shrubs of intermediate size.

Between herbaceous and ligneous plants is an intermediate link, consisting of plants which partake partly of the nature of each, but are dissimilar in some respects. These are termed sub-ligneous plants. The hard lower portions of the stems of these are lasting, and put forth fresh shoots every year; but the extremities of the shoots perish year after year, and are again renewed when the plant makes fresh growth. Among these may be named Sage, Rue, and Southernwood.—C. W. M.

(To be continued.)

Cultivation of the Melon.

The Melon is one of the most important of dessert fruits. Although the style of growth appears similar to the Cucumber, quite a different course of treatment is required. For the first crop seeds may be sown in December, and afterwards at intervals for succession; but no sowing should be made after July, for the Melon requires a long period of sun for ripening its fruits, and by the time those on plants raised at the end of July have attained their full size very little sunshine can be expected.

When sowing, one seed in a 3-inch pot will be sufficient, and a few more pots should be sown than the number of plants required. Place the pots in a temperature about 75°, and cover them with pieces of glass or paper. When the seedlings appear remove the covering, and afford all necessary light for keeping them sturdy. Prepare a hotbed of litter and leaves, and upon this place a layer of turves, the grassy side downwards. A narrow ridge of heavy fibrous loam, broken into small lumps, with a little crushed lime rubble added, is placed upon the turves. When the temperature of the bed has sufficiently cooled down to be safe the plants are inserted at a distance of 2 feet apart. Next, fix a wire trellis to the roof of the house to train the plants upon, placing it about a foot from the glass.

The plants when growing require copious supplies of water, both at the roots and in the atmosphere, taking care not to apply the water too near the stem, as that is apt to cause canker. Occasional applications of liquid manure are beneficial after the fruits are set, and when these show signs of ripening water must be gradually withheld. Syringing will be required on bright days, regulating it by the condition of the weather, for a too moist atmosphere inside the house on dull days causes the plants to canker. The paths of the house should be kept damp in bright weather; but when the plants are in flower both syringing and damping must be discontinued, as a dry atmosphere is required to set the fruit. After the set has been obtained recommence syringing and damping, and continue until the fruit begins netting, when damping alone will be sufficient, and even this should be stopped when the fruit changes for ripening. No shading will be required, as the Melon is a sun-loving plant.

The night temperature ought not to fall below 70°, and may be allowed to rise to 90° or 100° in the daytime Air must be admitted on bright days when the temperature reaches 80°, gradually increasing the amount as the temperature rises. The house must be closed early in the afternoon, with adequate moisture for the well-being of the plants.—Elveden.

(To be continued.)

Hardy Fruit Garden.

Propagating Strawberries.—The best and strongest plantlets showing a few roots at the base may now be layered in quantity on the surface of pots filled with good soil, on the soil or under surface of moist squares of turf, or in the natural soil between the plants in the beds. In the latter case, a little preparation may be necessary, loosening and breaking up the surface, if hard. A little fresh material, such as leaf soil, decayed manure, and old potting soil lightly worked in, will be of assistance in retaining moisture, and so promoting the early emission of roots. Secure the plantlets in position by hooked pegs or stones.

When pots or turves are used, sink them slightly in the ground; 60 size or 3-inch pots are the most suitable. No more drainage is required than can be afforded by one crock at the bottom and a piece of fibrous turf. Loam and manure in equal parts pressed firmly in the pots is the best compost. By all means select runners from fruitful plants. Daily waterings in dry weather are imperative, especially for the pots, which frequently require water twice a day. Cut off the runner wires beyond the plantlets. Superfluous runners ought to be thinned out so as to afford those selected the most favourable conditions for rooting freely and growing sturdily.

Summer-pruning Apples and Pears.—The long foreright shoots or breastwood issuing from the main branches of trained trees on walls, pyramids, and bushes in the open, require now to be gradually pruned back. Select the point of shortening immediately above the fourth good leaf, counting from the base of the shoot, though not including the small examples known as the small basal leaves. Commence in all cases where the growths are strongest, such as the upper parts of trees, working gradually downwards to the weaker parts. It is a good plan to divide the removal of the whole of the shoots into two or three operations, which will not make the check to growth so sudden. This may very conveniently be carried out when a number of trees require treatment by going over the upper parts first. Trees in a generally fruitful condition do not produce long annual shoots to the same extent as those in a less satisfactory state, therefore the first summer prunings can be completed on each tree in one or at most two operations.

If sappy or rampant shoots appear, cut such out entirely. They usually issue from the old wood, and are seldom required. They are not often found on trees well furnished with fruiting spurs.

Young trees still extending main branches ought not to have the leaders shortened, but the side shoots or forerights should be shortened as indicated to the fourth leaf. This assists the formation of spurs naturally and artificially.

Regulating Wall Tree Growth.—Frequent attention must be given throughout the summer to wall trees needing to be kept furnished with wood for bearing. Apricots, Peaches, and Nectarines, as well as Morello Cherries, Figs, and to some extent Plums and Sweet Cherries, are provided with bearing wood by the annual laying in of young shoots. Those growths which have previously been secured in the proper position will only demand slight attention now, simply nailing or tying in the parts which have extended. The objects attained in doing this are riper wood, and a more finished appearance of the trees, together with the early removal of superfluous shoots. The freer admission of light and air is secured, which acts upon the foliage retained, finally completing the full maturation of the wood and buds.

Outdoor Vines.—The full exposure of the principal leaves is important. Break out all laterals issuing from below the bunches of fruit. The side shoots having been stopped one or two joints beyond the bunches, lateral shoots will require repressing at the first leaf. This will prevent overcrowding and shading of the fruit and large leaves. Reduce the number of bunches to one on a shoot, and thin out half the berries. If successional shoots from near the base or other parts are being trained in give them space to develop.

Outdoor Figs.—Shortening the summer shoots of Fig trees intended to be retained for future bearing must not be practised. Shoots bearing the fruit this season require pinching a few leaves beyond the fruit. These growths may eventually be cut out. Crowded growths should be thinned, and foreright, ill placed, and rampant, strong and sappy shoots cut out entirely. Those retained train in neatly and regularly to the wall or trellis, leaving them full length.

Removing Suckers.—Suckers spring up freely round Plum trees. These ought to be carefully dug up or pulled out. When roughly cut off just below the surface they soon appear again. All sappy shoots that spring from below the soil round Gooseberry trees should also be cleared away. Cuttings properly prepared when propagating do not produce trees that form suckers. The sucker growths from Raspberries may also be thinned out round the stools, and those a distance away dug up.

Fruit Forcing.

Vines.—*In Pots for Early Forcing.*—The canes for starting the first week in November, to ripen the fruit in March or early in April, should by this time have completed their growth, and must not have any more water than will prevent the foliage from becoming limp. Expose fully to light and air, so as to thoroughly ripen the wood and the buds. If the laterals have been allowed to extend with a view to thickening the cane, they must be brought back gradually by cutting away part at a time, reducing each by degrees to one leaf. The Vines should be kept free from insects, syringing occasionally if red spider appear, for it is important that the leaves perform their functions. When the wood becomes brown and hard, place the Vines on a board or slates in front of a south wall, securing the canes to its surface to prevent the foliage being damaged by wind. Afford water only to prevent the leaves flagging; cut away the laterals close to the cane, and in a few days shorten the cane to the length required. The principal leaves must not be injured, but left to die off naturally. The best varieties for early forcing are White Frontignan, Foster's Seedling, Black Hamburgh, and Madresfield Court. Later Vines should be encouraged to make a good growth and perfect it, keeping them clean, also exposed to all the light and air possible. They must not be overwatered, nor neglected for due supplies of water or liquid manure. Cut-backs are much the best for early forcing, as the Vines make an earlier and sturdier growth, and perfect it sooner than others. This is important, for the Vines have more rest and start with greater regularity.

Early Forced Planted-out Vines.—It is not advisable to force Vines year after year to ripen their crops before May or June, and houses which are started in December or at the new year to afford ripe fruit at the times mentioned respectively are best planted with varieties that ripen together, the structures being only of sufficient size to admit of a supply of Grapes for a period of not more than six to eight weeks. This is as long as black Grapes will hang under a May, June, and July sun without turning red, or white Grapes from becoming brown on the exposed side of the bunches, even when a slight shade is afforded from sun. Such arrangement admits of the foliage being cleansed with water from a syringe or engine, but when there are late as well as early varieties in the house the dry atmosphere that must be maintained on their account when the Grapes are ripening causes red spider to increase on the foliage, and this is very disastrous to present and future crops of Grapes. Early Vines that ripened their crops in May or early June

will soon be cleared of Grapes. They shonld be thoroughly cleansed employing an insecticide if necessary, and the foliage be preserved in health as long as possible by occasional syringing, full ventilation constantly, and due supplies of water or liqnid manure at the roots.

Muscats Ripening.—Unless the season is exceptionally fine, and tbe Vines started early, Muscats reqnire fire heat to insure their perfect maturation, even when ripening at the hottest part of tbe year. The time taken by Muscat of Alexandria to ripen is not less than six to eight weeks from commencing to colour, and if the Grapes are extra fine, and the Vines in vigorous healtb, perfect finish is not bad for some time longer. They require time, with assistance from fire heat, so as to secure a night temperature of 70°, 75° to 85° by day, up to 90° or more, with abundance of air. A ratber dry atmosphere is essential to tbe attainment of tbat golden hue characteristic of rich and full Muscat flavour. This is secured by free ventilation, a little constantly, but the atmosphere must not become arid, damping down occasionally. In large houses the moisture arising from the borders is enough, except in hot weather, then the borders and patbs should be damped daily. Too much moisture is fatal to Muscats when ripening, causing them to "spot," tberefore it is necessary to have a gentle warmtb in the hot-water pipes, and a little air constantly to prevent the deposition of moisture on tbe berries. Abundant supplies of water must be given to the roots, for when tbere is a deficiency of moisture the Grapes shrivel. With the borders properly constructed, and the drainage thorough, too much water can bardly be given at the roots, after the leaves are full-sized, until the Grapes are well advanced in ripening. Needless waterings, however, are baneful, causing shanking, and driblets, mere damping of the surface, very ineffective, doing quite as much harm as good, besides being deceptive of the right indication of the soil beneatb as regards moisture.

Young Vines.—Canes planted this season should, provided they are to be cut down to the bottom of trellis, leaving tbree buds there for furnishing a continuation of tbe rod and two side sboots for bearing next year, be allowed to grow unchecked, so as to secure a good root formation and sturdy stems. Any Vines intended for producing full crops next season on the extent considered sufficiently stout in rod, should have the laterals issuing from the side of the buds to which they are to be shortened, stopped to one leaf, and the principal leaves kept free of growths. If permanent Vines tbe cane need not be shortened till it has grown to the top of the bouse, cutting back at tbe winter pruning to three good buds from the bottom of the rafter or trellis, and only allowing the side growths to bear each a bunch of Grapes in the second year to prove the variety, taking the leading growths forward without cropping. Supernumeraries intended for next year's bearing and then to be removed should be stopped at a length of 7 to 9 feet, pinching the laterals to one leaf, and sub-laterals in like manner. Tbese ought to be shortened in September, and by degrees cut away close to the cane, and in a fortnight afterwards the Vines should be pruned to the first plump bud below tbe first stopping, leaving tbe old leaves to die off naturally. Thorough ripening of the wood is important, a free circulation of air being necessary. with fire heat if tbe weather be cold and wet.

Melons.—*Stopping and Removing Growths.*—During moist and warm weather tbe plants grow rapidly, and should be gone over at least once a week, and in tbe case of vigorous plants twice, for the removal of superfluous shoots, tbe principal growths being fully exposed to ligbt. Overcrowding is the greatest evil in Melon culture, because the excessive foliage mnst be thinned, and its removal results in exudation from the wounds, gangrene sets in, and the affected parts perish through "wet rot" (bacterial growths) or mould (fungoid developments). To arrest tbese antiseptics must be used. The best for the purpose is quicklime, rubbing it well into the affected parts, and repeating as necessary. But the worst effect of removing a large quantity of growtb is giving a check to the fruit, not unfrequently causing it to cease swelling, and it becomes hard in the flesh. Fungoid growths fasten on the exudation, and moisture settles on. the fruit, commonly at the blossom end, where ripe rot fungus obtains a seat, and gaining access to the flesh causes it to decay wben it should ripen. Tbese disasters are generally preventible by attending to the thinning and stopping of the growths. Therefore when the fruit is set and swelling tbe laterals should be pinched to one leaf, and if this results in too much foliage, so tbat the leaves on the primary growths are crowded or shaded by them, thinning must be resorted to, removing a little at a time.

Watering.—If Melons are kept too dry a check is given that will canse the plants to collapse before the fruit is fully developed, and that ripens prematurely. The great point is not to allow flagging at any time, and yet not to give water until the soil is getting rather dry, when a thorough supply shonld be afforded. Plants witb a large extent of rooting space usually need water or liquid manure once a week, those with less rooting area twice a week, and those in pots or boxes once or twice a day. Regard mnst be had to the weather and the actual needs of the plants. When setting and ripening it will be sufficient to keep the foliage from flagging, and if watering is necessary it sbould be given without wetting the surface more than can be helped.

Damping and Syringing.—At the time of setting and ripening moisture must be entirely withheld from the atmosphere, but tbe paths and walks of houses may be damped in tbe morning and early afternoon, or occasionally only in not very bright weatber. When the blossoms are about expanding witbhold water from the foliage or the fruit will not set, and when the fruit is ripening it must not be wetted or a close moist atmospbere kept, as these are fatal to flavour and often the cause of the fruit cracking. With the fruit swelling syringe well at closing time, and if morning syringing is practised it should be done early; but the liberal damping of the paths is better than wetting the foliage. Plants in frames shonld be sprinkled at closing time, being careful to keep the water from the neck or collar of tbe plants.

Temperature.—In most cases fire heat is not now reqnired, as witb due regard to early closing tbe night temperature may be kept from falling below 65°. In dull periods, however, a little fire heat may be desirable to maintain a buoyant atmosphere when the fruit is setting or ripening. Plants at those times are better for linings, so as to allow of a circulation of air, otberwise the temperature will be ruled by external conditions, yet it ought to be maintained at 65° at night and 70° to 75° by day.

Ventilating.—Nothing answers better than leaving a little air on at night to prevent excessive moisture, increasing the ventilation early in the morning of fine days when the temperature bas advanced to 75°, and gradually increase it witb the rising beat, keeping through the day at 80° to 90°, and closing sufficiently early to rise to 95° or 100°, and before nightfall admit a "crack" of air at the top of the bouse. When tbe fruit is ripening admit air freely, a little constantly, as it is moisture on tbe rind and pent up moisture in the fruit that causes cracking. Likewise when the fruit is setting allow a circulation constantly, as moisture on the fructifying organs causes their destruction.

Routine.—Put supports to the fruits before they become beavy and kink the Vine, letting the board slant so as not to bold water. Place slates beneath the fruits of plants in frames, raising the Melons as they advance in swelling on inverted flower pots above the foliage, but retaining the slates for the fruit to rest on. After a period of dull weather it is desirable to afford a slight shade for a few hours in the hottest part of the day to prevent the foliage flagging, and tender fruit from being scorched. A slight shade is useful over fruit in the ripening stage when it is exposed directly to the sun, especially when the plants do not, from indifferent vigour, supply moisture to the fruit freely.

Insects.—Black apbides sometimes become troublesome. The best remedy is fumigation with tobacco paper on two or tbree consecutive evenings, taking care to bave the foliage dry and to deliver the smoke cool. Avoid an overdose and mat up frames to keep in the smoke. Thrips also yield to tobacco smoke. For red spider there is nothing better tban proper moisture in the atmospbere and soil. A little flowers of sulphur on slates so that tbe sun can act upon it gives off fumes bateful to red spider and fungous pests. Canker is caused by damp in many cases, but it is inherent in some varieties. It is averted by a drier atmosphere and keeping water from the stems; to arrest it rub quicklime into the affected parts until dry, repeating if necessary. By tbose means tbe plants can generally be kept alive until the crop is perfected.

THE FLOWER GARDEN.

Carnations.—If not already done a mulching of old Mushroom-bed manure or leaf soil should be given Carnations after very lightly loosening the surface, and giving a good watering. Tbis will serve to prolong tbe display considerably. The Margaret Carnations, if raised moderately early and duly planted out, will flower strongly in August or September, tbough not if they are topped; give these also the benefit of a mulch.

Propagating Carnations.—If the smaller side shoots are slipped off now these will root quite as readily as Pinks in a frame or handlights placed at the foot of a north wall or fence. In warm moist localities bottom heat may be dispensed witb, but a very slight hotbed is of good assistance. Pack enough material inside the frames to raise about 4 inches of loamy gritty soil well up to the light, and face over with sharp sand. Little or no trimming is required by short slips, but longer cnttings or any upwards of 4 inches in length should be shortened, not, however, by cutting with a knife, the better plan being to pull tbem cleanly apart at a joint. Fix them firmly in the soil, give a gentle watering, and keep close and shaded from what brigbt sunshine reaches the frame till rooted.

Saving Pink Seed.—Seed if ripe may be either stored till next spring, or else be sown at once. When quite new yet properly ripened it germinates quickly either on a well prepared border or in boxes set in a cool shady position. If not sown very thickly neat little plants will be formed before the winter arrives, those in boxes being kept in cool frames. Mrs. Sinkins, and varieties raised from that robust popular form, come quite true from seed, and young plants partaking somewhat of a perpetual flowering character are more likely to flower the same season they are planted out than are the more delicate varieties.

Hollyhocks.—Red spider can be destroyed by mixing a handful of flowers of sulphur into a paste and then mix it with two gallons of clear water, and with a syringe tboroughly wet both the under and upper surfaces of the leaves. Black fly is also prevalent on Hollybocks in some gardens, and this may be got rid of by means of tobacco powder or strong snuff, puffing this well over the under side of the leaves. No side shoots should be allowed to grow on any of the plants. They ought to be kept well supplied with moisture at tbe roots, and be given a mulching of short manure. If leaf buds are found at the axils of the leaves of any side shoots removed, tbe latter may be cut into short lengtbs, placed singly in small pots, and rooted in a gentle but not very moist heat. All that develop into plants should be shifted into larger pots before they become much root-bound.

Dahlias.—Old stools push up very many more shoots than should be left to grow, much better results following upon tbe practice of confining the plants to a single stem, or at the most two stems. These being kept properly secured to a strong stake, will branch strongly and produce either a few extra fine blooms for exbibition purposes, or an abundance of ordinary good flowers. If the former are desired about

four stakes should be placed to each plant, and some of the best placed branches be fastened to these, the rest being cut away, or better still early pinched out. Dahlias require abundance of moisture at the roots, a good mulch of strawy litter further serving to keep the ground cool and moist.

Gladioli.—Stakes should be placed to these before the spikes become heavy, frequent syringings and waterings also being necessary if fine spikes and large flowers are desired. In order to have the spikes for exhibition with the flowers well together and all facing one way they ought to be enclosed in a V-shaped trough, made by nailing two long thin pieces of board about 4 inches wide to a strong stake. With the aid of these troughs it will also be an easy matter to shade the lower flowers with newspaper, with a view to keep them fresh and of good colour to match the upper flowers.

THE BEE-KEEPER.

Honey Prospects.

The first week in July has been dull and cold, and as there has been little sunshine, this combined with a low temperature and high winds has kept the bees comparatively idle. This is discouraging to bee-keepers, as in this district the bee forage has been better than usual. The white Clover is still a mass of bloom, and the Limes are just opening their flowers; but unless a change soon takes place in the weather the honey crop will be a light one. It, however, illustrates what I have often stated—that, given fine weather, bee-keepers in this country could hold their own both in quantity and quality with bee-keepers in any part of the world. In some countries fine bright weather may be depended on for several weeks in succession, and a large surplus of honey is stored in consequence, although the flowers from which the finest samples of honey are obtained are not nearly as plentiful as during the honey flow in favoured districts in this country.

As is well known to all bee-keepers, white Clover yields a superior sample of honey; and showing to what an extent it is cultivated in some parts of the country, I may state that within a radius of two miles of my apiary there is nearly, if not quite, 500 acres grown. Bee-keepers can imagine the benefit bees derive from such a source if the all-important factor the weather is favourable; but when day after day is sunless, or nearly so, and the flowers are gradually dying after being developed for several weeks without the bees obtaining any benefit from them, it is discouraging.

From numerous letters received, I am inclined to think that the honey harvest has been much better in the south and west of England than it has been in the northern and midland counties. "S. T.," writing on the 30th ult., says, "I am busy extracting from full sized frames worked on the doubling system, as advocated in the *Journal of Horticulture*. My first eleven frames gave me 60 lbs. of beautiful honey. My numerous shallow frames and sections are well sealed over. I, however, prefer the standard frame for doubling, and shall use it more largely in the future, as a greater bulk of honey is obtained, and not so much risk from the bees swarming." The above is very gratifying, and shows what can be done under good management, where the bee forage was at least a fortnight earlier than in this district; and as much more favourable weather for honey production prevailed at that time, it will doubtless be found at the end of the season that bees in the more forward districts will have done much better than those in the later parts of the country.

Bees in Straw Skeps.

Bees that are in skeps, whether old stocks or swarms, may be utilised in many different ways without destroying the bees, and a much larger surplus can be obtained than by working on the orthodox system associated with straw skeps. If a glass super is placed on the top of skep, which is still done by many bee-keepers, at the most it will only hold a few pounds of honey. The same may be said if the bees are allowed to swarm, and after they have filled the skep with combs no extra room is provided for them. Of course under the modern system a crate of sections may be worked on the top of a skep and be as well finished off as those placed in an elaborate and more expensive bar-frame hive.

At the present time I have several straw skeps that for weight of honey will compare favourably with my frame hives. Although the honey may not be of as good quality according to modern ideas, still some of my customers ask for it; there is therefore no difficulty in finding a market for it when obtained. Early in the spring the bees in straw skeps were encouraged to breed early by being fed daily, and as they were kept warm they increased at a rapid rate. By the first week in May they were ready for swarming. An artificial swarm was then taken from each in the usual manner, care being taken that sufficient bees were left in the skeps to cover the brood, and to raise a young queen. The bees so obtained were placed in frame hives with fully drawn-out combs, each stock being given a frame of brood taken from a strong colony. They increased at a rapid rate, and were afterwards used to obtain a surplus in the usual manner.

Bees from Skeps to Frame Hives.

Three weeks after the queen and worker bees were driven from straw skeps the same operation was again repeated, until the young queen, which had now hatched out, was seen to run up into the empty skep with her attendants. These were then shaken into a skep filled with clean combs, the hole in the crown being covered with a piece of queen-excluder zinc. The skep from which the queen and bees had been driven was then placed on the top of skep containing the queen, the latter being kept in the bottom skep by the excluder zinc on the top, through which the bees would gain access to the combs in the skep, which now formed a super. Within a few days the young queen had become fecundated, and was laying. As soon as the combs were filled with brood the driving process was again repeated until the queen was seen to run up into the empty skep.

The queen and bees were then placed in a frame hive on frames of fully drawn-out combs, a sheet of queen-excluder zinc being placed on the top of frames. The two straw skeps were then placed on top of frame hive and covered up warm. The queen is now filling the frame hive with brood, the honey being taken into the skeps which form supers over the brood nest. When the honey flow is over all that is necessary is to remove the skeps a short distance from their stand, and the bees will fly home, or they may be driven in the usual manner. A strong colony headed by a young fertile queen will now be in the frame hive, which if supplied with sufficient stores will doubtless winter well and come out strong and healthy in the spring, and may then be used for whatever purpose they are required.

This is a simple way of working bees from skeps into frame hives, as the operation does not take many minutes to perform, for directly the queen is seen to run up into empty skep the drumming should cease, as the workers will not leave the queen without supplying her with plenty of attendants. If there is an objection to honey obtained from a straw skep it may be removed from the top of frame hive as soon as the brood is all hatched out, and a crate of sections or shallow frames placed on the top instead of straw skep.—An English Bee-keeper.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," *8, Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Thrips on Vines (*A. F.*).—The best means of dealing with thrips on Vines is to fumigate with tobacco paper or vaporise with nicotine essence. There are self-acting fumigation rolls and other advertised preparations, all answering for the destruction of thrips. It is necessary, however, to repeat the fumigation, at intervals of about four days, two or three times, so as to destroy any hatching out from the eggs, which are not reached destructively by the fumigation or vaporisation. Sometimes, also, stray thrips escape being killed, hence the need of following up so as to get rid of the pests effectively. With care, neither the smoke nor vapour will injure the foliage; but, of course, it must not be overdone, and the foliage must be dry.

Photograph of Grapes (*Barry Dock*).—One of the best photographs of Grapes we have seen has been sent to us, but as it contains no endorsement, and as a letter referring to these Grapes cannot he found, we shall be obliged if the grower of them, if this request should meet his eye, will communicate with us on the subject. We have been informed that they have been grown by following instructions which have been given in the *Journal of Horticulture*.

"Rust" on Grapes (*Blakedown*).—This is occasioned (1) by excessive moisture suddenly evaporated from the berries, such as allowing the house to remain closed for a time in the morning when it ought to have air, and then throwing the ventilators open; (2) rubbing with the hands or head in thinning, &c.; (3) steam arising from hot-water pipes; (4) using hard or irony water for syringing; (5) fumes of sulphur arising from it on hot-water pipes; and (6) sudden depressions or fluctuations of temperature. It may also arise from insect or fungoid attacks, but generally through cultural defects.

Judging Flowers (*H. W. G*).—We do not know whether all judges have a copy of the Royal Horticultural Society's Judging Code with them when adjudicating at shows; but we know that some of the most experienced judges have it in their possession. Not judges only, hut exhibitors, should have a copy of the rules for reference from time to time, as may he needed. This Judging Code, which contains the chief points of merit and defects in various kinds of flowers, fruit, and vegetables, can he had in return for 1s. 1d., sent to the Secretary, Royal Horticultural Society, 117, Victoria Street, Westminster.

Exterminating Cockchafers (*Chy*).—The hest plan of dealing with the adults infesting trees is to place sheets on the ground in the morning, or on dull days early in the afternoon, when the beetles are clinging beneath the leaves, and are dull and not likely to take wing. They may he swept together, after shaking off the trees or shrubs, and destroyed. There is no better plan than the shaking down to get rid of the heetles, hut children on a summer's evening will catch hundreds with an ordinary butterfly net on a cane. We hardly think, however, that you have the May hug (Melolontha vulgaris), but the June bug, or lesser May bug (Phyllopertha horticola), generally the commoner insect, and usually confounded. Both have a similar life history. After pairing the female hurrows into the ground to a depth of about 6 inches, and deposits thirty or more whitish or pale yellow eggs, from which hatch small whitish-yellow grubs, and in the spring feed on roots of growing plants, where they soon become thick and fleshy, and often so shear off the roots as to make the affected plants wither, especially grass on lawns in had cases. In the winter they descend deeper into the soil, hut only to come up again the following spring and pursue their feeding. Thus they work for three seasons until full-fed, when the gruhs are large and descend deep into the earth, sometimes 2 feet or more, change to pupæ in oval cells, becoming perfect insects hy the following spring, and in due course appear ahove ground. At that time the starlings are ready to receive them, as they have young with strong appetites, and poultry delight in the chafers, also pigs. Thus in May, June, and July the beetles appear in the fourth year from the depositing of the eggs. For the grubs there is nothing better than a dressing of kainit and nitrate of soda, 7 lbs. of the first and 1¾ lb. of the latter per rod, applying when the gruhs are active near the surface. The amount named is for had cases; in moderate affections half quantity suffices.

Melon Leaves Diseased (*D. J.*).—The leaves have succumbed to the attacks of a fungus, Phoma lanigera, which, hy its mycelial hyphæ in the tissues, causes them to wither as if scorched. The germ tubes from the spores of the parasite enter the leaf tissue where the spots appear, and the minute pustules or receptacles of the "fruits" appear later. In some seasons the pest is very troublesome, as it causes the destruction of the foliage to a great extent before the fruits are fully swelled, and they in consequence do not finish, while in had cases the plants die from the leaves downwards, being perfectly sound in stem and roots, yet so affected as not to push laterals, and the fruit cannot possibly swell or ripen. The cause is the spores of the fungus gaining access to the plants, but how is matter for speculation, and the predisposition commonly arises from excess of vegetahle matter in the soil, with a somewhat close and moist atmosphere. The best preventive we have tried has heen the addition to the soil of calcareous matter; we having used hasic slag phosphate, a good handful (4 ozs.) per square yard, mixed with the soil after placing in the hed, with good effect. The hetter plan, however, is to use a mixture of hasic slag phosphate and kainit in equal parts, sprinkling 2 ozs. of the mixture on each square yard of the turves as placed in the layers of about 3 inches thickness in the autumn. The lime evidently gets converted into nitrate, and thus readily taken up hy the plants, appears to act against the inroads of the fungus. We have also found that top-dressings of the advertised fertilisers act well as preventives by fortifying the plants with lime and other mineral elements, so that they successfully resist the fungus, especially when the structures are well ventilated, particularly in the early part of the day, so as to prevent the germination of the spores. Indeed, air appears the best preventive combined with lime in the soil. We have known a dressing of three parts bone superphosphate, one part muriate of potash, and half a part sulphate of magnesia, mixed, using 2 ozs. per square yard, to act well; but the usual fertilisers contain these ingredients, and are handy.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can he named at once, and the numhers should he visihle without untying the ligatures, it being often difficult to separate them when the paper is damp. (*C. G. M.*):—1, Habrothamnus elegans; 2, Coprosma Bauriana variegata; 3, Centropogon Lucyanus. (*D. S.*).—1, Odontoglossum citrosmum; 2, Cassia corymhosa. (*T. C. R.*).—1, Tradescantia virginica; 2, Lucalia gratissima; 3, Centaurea speciosa; 4, Alströmeria aurantiaca; 5 Astrantia minor. (*V. Z.*).—Crinum capense. (*R. P.*).—If growing under glass the specimen is Jasminum rubigerum, if out of doors J. revolutum.

CROP PROSPECTS AND THE FOOD SUPPLY.

IT has been generally understood of late—that is to say, during the last few months—that the world's supply of Wheat, and other breadstuffs equal to Wheat, has been barely sufficient for the demands which would be made upon it before the forthcoming harvest could be placed upon the market. That this idea may have been an exaggerated one is probable, for the price of Wheat has

steadily declined since the autumn, and is falling still; yet the fact that the sufficiency of the world's food supply has been called in question lends additional interest to the prospects and estimates of the produce of the crops now growing. Our own crop is so insignificant in proportion to the world's growth, that it is hardly worth taking into consideration; but we may observe in passing that though the Wheat crop cannot approach the fine crop of last season, owing to thinness of plant, it may yet turn out to be an average one.

The chief interest as regards foreign Wheat supply centres in America. The June report of the American Department of Agriculture has been published, and should give us a good estimate of the position of the growing Wheat in the United States. The great difference between this report and the unauthorised newspaper or trade reports previously published, is very marked, and it is quite evident that either a great change for the worse has come over the American Wheat crop, or that organised and systematic attempts have been made to unduly "*bear*" or depress the markets for speculative purposes. To take the case of the Wheat in California, the condition of the crop in May was stated to be 97 per cent. of a full crop; but the official report only estimates the condition for June as 73 per cent.

The condition of winter Wheat in the States taking the whole country is 78·5 against 80·2 for May, and 77·9 for June, 1896, whilst the acreage has been reduced by 1,232,000 acres in the year, or more than 5 per cent. The condition of spring Wheat is 89·6, or 10·3 less than last year, but the acreage is larger by about the same amount that the winter Wheat has decreased. Taking winter and spring Wheat together the condition is 82·7 against 87·6 last year, thus we have a 5½ per cent. diminution in condition on a similar acreage. The statements that have been made that the crop would be one much heavier than that of 1896 must therefore be very far from the truth; on the contrary, a much smaller yield must be expected, and English farmers must take this into account when estimating the probable run of prices for the winter.

On the continent of Europe crop prospects vary considerably. In France things are not promising, and expects a deficiency of 6,000,000 qrs. on the year. In Russia, Hungary, and Roumania a very similar state of things prevails. Spain, Germany, Holland, and Italy report an average prospect, but nothing more. India has not yet recovered from her year of famine, and at present will be fully occupied in supplying her own needs; whilst in Australia and Argentina the weather conditions have been very unfavourable. Taking the world's Wheat therefore as a whole there is little probability of a fair harvest; indeed, there is every likelihood of a poor one. There have been so many scares in the past as to the possibility of a food famine on a small scale, scares which have been proved to be entirely unfounded, that the consumer has become lulled into a sense of security. We trust the awakening may not be a rude one, for a very small real deficiency would lead to a very large increase of price.

We think we have shown that there is good reason for believing that Wheat will not come any lower in price, but will more likely have a rise. As regards Barley it is to be feared that another tale will have to be told. The growing crops look well enough, and we should think that the yield so far as we have observed will be an average one; also the straw is not too long, and appears able to keep upright if the weather be anything like favourable. But Barley is now imported from so many new sources, and so much of it is sounder and paler in colour than our own, that maltsters and brewers can afford to look on with equanimity when, as last season, the English farmer's crops are being ruined.

Our readers may remember how rapidly the price of sound Barley rose during and immediately after the disastrous weather of last September. The brewers were alarmed and anxious about their malt supplies; but what was the outcome? Fine Barley from abroad was provided in abundance, and before the season was over the price of fine English had fallen 10s. or 12s. per quarter. With an experience like that fresh in our minds, can we expect to get much more than 25s. for our Barley, even if it be good enough for Bass?

Oats have been suited by the recent forcing weather, and will be much better all round than last year, which will help to make up for lower prices which are certain to prevail.

We are very curious to see the agricultural returns with the present acreage under Potatoes. There is hardly a grower to be found who does not confess to having reduced his acreage of Potatoes. In some cases not half as many are being grown as in 1896, and we shall be much surprised if we do not see something very striking in this direction in the returns. The crop promises fairly well, but is backward; as, however, there is a large increase in the proportion of early varieties as compared with late ones, there will be an ample supply during the early months of the season. The diminution in the area of good-keeping kinds may make itself felt as spring approaches. The Potato grower needs a turn, having had two bad seasons in succession, bad, not from the smallness of the crops, but owing to very inferior quality and too much bulk.

If growers could only be induced to combine in growing high quality the crop would be a paying one, but the Giants and Colossals now grown so largely draw heavily on the land, and only benefit the salesmen and the railway company.

WORK ON THE HOME FARM.

We have had a fine week, and very fortunate has it been, for what with haymaking and Turnip hoeing we have not known which way to turn first. Mangolds having been backward have wanted attention just when the Swedes were beginning to do so, and the later Turnips having grown more rapidly than either, all the striking and singling wants doing at once. So necessary is it to have Turnips thinned out and weeded at the proper stage of growth, that we are allowing some of our hay to stand a little longer.

Swedes are all singled, but will require looking over again for weeds, those struck out during the wet weather having grown a little between the rows, and the few weeds it is inevitable to leave behind being now much in evidence, and soon will be in flower. The horse hoe must be kept constantly at work as long as it is possible to get it between the rows comfortably.

It has been splendid weather lately for the hay, windy, with not too much sun. The Clover and grass have made beautifully, without being unduly shrivelled. A continuance of such weather for another fortnight would see the hay harvest finished, and with a fine crop well gathered the farmers of the country would have great cause for self congratulation.

Having got the Mangolds hoed, we are now giving them a top-dressing of sulphate of ammonia at the rate of 2 cwt. per acre. There is nothing better for Mangold than this. The roots grow rapidly, get a good size, and are very solid and sound. The few bits of corn laid by the rain has been blown up again by the wind, but there has been quite wind enough for the corn generally, as the ears begin to fill and gain in wet the high winds knock them about sadly.

Pastures are now good everywhere, and by emptying a field or two where the grass has run away from the stock and running the machine over them an extra hayrick may be picked up easily and put by until there is a less favourable season.

The horses have had an easier time of late, and are now eating vetches without corn; in fact, we knock off the corn for a couple of months from midsummer. This course has an excellent effect on the limbs and general health of the animals.

REMARKS.

4th.—Bright early; alternate cloud and sunshine during the day.
5th.—Bright early, generally cloudy from 8 A.M.; a little rain at night.
6th.—Fine, but generally cloudy, and overcast at times.
7th.—A sprinkle of rain early; fine and sunny throughout the day.
8th.—Generally sunny in morning, but much cloud in afternoon.
9th.—Overcast morning; bright sun at times in afternoon.
10th.—Bright sunshine throughout.

Another very fine week, but with no very high temperatures.—G. J. SYMONS.

Journal of Horticulture.

CHISWICK:
Its Work, Wants, and Possibilities.

BEYOND a passing allusion, or brief records of the decisions of examining committees little has been said in these columns of late on what may not be inappropriately referred to as this ancient and modern seat of experimental horticulture.

There was a time when Chiswick seemed almost to be abandoned by those who were responsible for the conduct of the Royal Horticultural Society. The gardens were starved, the structures neglected, and the resources of the late Superintendent, who conducted them so well over so many years, were often taxed to the utmost in keeping them in presentable condition, and the crops in a healthy state.

For some time, however, prior to Mr. Barron's well-earned rest from active labour, both the disposition and the means were forthcoming to give better support to the famous old enclosure, the result being steady progressive improvement. The foundation was laid in recent years for still further progress, and while it must in justice be said that the present Superintendent has made the best of his opportunities, he would be the last man not to recognise and appreciate the share of the able gardener whom he has had the honour to succeed, in bringing them into the present satisfactory state.

An opportunity was afforded on the 14th inst. for a considerable number of scientific and practical men to inspect the gardens and spend a most enjoyable day therein. The President and Council of the Royal Horticultural Society issued cordial invitations to the several members of the respective Committees to meet them on the occasion, and a concise programme was prepared for the guidance of all. It was briefly (1) the inspection of the gardens at 12 o'clock, (2) luncheon at 1.30, (3) discussion at 3 o'clock, terminating at 4.30—a business-like allocation, and convenient to many busy men. "Time" was kept with admirable promptitude, and it will be admitted by all who had the good

fortune to be present that every item in the programme was highly appreciated.

The day was one of the brightest and hottest of the season, but this did not deter most of those who assembled from making a thorough exploration indoors and out, seeing what was to be seen, and it may safely be said that little was missed in any of the departments. Those who could enjoy, as surely all must, a sight in the cultivation of Figs in pots had the opportunity of admiring, no doubt, the finest and best-grown collection of trees in Europe. Many of them were collected by the late Dr. Hogg. They were preserved and cultivated by Mr. Barron for many years, and it is fortunate that they have fallen into able hands. The present condition of the trees are a credit to all who have "handled" them, and a cherished possession of the Society.

Then the Vines were not overlooked, as they could not well be; for apart from other structures, have we not here the finest vinery of its kind in the kingdom, the large and lofty curvilinear span-roof, with its ladder on wheels like a gigantic moveable bridge, for attending to the Vines and thinning the four or five thousands of bunches of Grapes? The Vines are old, but show no deterioration in the condition they have presented any time during the past twenty years; but, on the contrary, invigoration.

This has been brought about mainly by a reduction of old rods and the increase of young canes, which produce better foliage, bolder axillary buds, and, consequently, finer bunches of Grapes than can possibly be obtained by the stereotyped close pruning of small laterals from generation to generation. It was also understood that there had been some "notching" of large fibreless roots in the hope of inciting the production of food-gathering fibres in the upper layer of soil. More time is needed for proving the results of the experiment, but having regard to the effects of similar practice we shall be a little surprised if still greater improvement does not follow in these forty-year-old Vines.

But speaking of surface fibres in a border previously destitute of them, it is possible that some of the visitors may not have observed a striking example of their quick production by a method as simple as it has proved effectual. It is not new, neither is it common, but because it has succeeded is worthy of mention here. As a matter of fact, the interlacing mass of quill-like roots referred to could not be seen by passers through the long and much too narrow structure without moving the thick mulching of lumpy manure under which they are happily working to the obvious advantage of the Vines. We have seen below the surface, however, and believe that more fresh young roots have been induced to take possession of the border in six months than could have been discovered at any time during the past six years. Will they remain? We must wait and see. We have known roots to permeate this narrow inside border before, and then depart either downwards or outwards, no one knows where. They have simply escaped, as Vine roots will sometimes, through some cause not easy to discover.

But how were they produced? We have said the structure is narrow. It is a mere glazed corridor, nothing like half wide enough. It would pay to widen it, and pay well. We know well that the idea of making Chiswick "pay" is shocking to some excellent educationists who have souls high above such sordid work as market gardening. We do not quarrel with them. They are right from their own point of view, but it is a point of view that is becoming obsolete by the great majority of students who are seeking knowledge in gardening. "Do nothing with the object of making Chiswick pay" was the substance of a letter read at the afternoon meeting; but it contained this significant proviso—"except it may be necessary for the instruction of the students." Exactly. That is the whole case. Students, above all things, want to see and learn those methods by which the greatest and most profitable returns are produced. Let science and practice go hand in hand, achieve the best results, and prove that they are so. If that is not educational, what is it?

There is no necessity to make Chiswick a "market garden" in the ordinary acceptation of the term. It should be essentially a garden of instruction, and show, so far as is practicable, the results of cultivation as based on sound principles, with contrasting examples of erroneous methods and the penalty of failure arising therefrom. Let it do that in Grape culture, Peach culture, Tomato culture, or any other culture, and let the reasons for success in one case and the cause of failure in another be clearly and precisely set forth; and here a scientific coadjutor might be of advantage in not only tracing effects to their cause, but making clear in exact terms the reasons for the differences that had to be recorded.

Returning to the Vines, which might have been made to illustrate in the most convincing way the value of the means resorted to for accomplishing the object desired. They had reached the limit, all too short, of extension. Nothing but repression, which, under the circumstances, amounted to mutilation, could keep them within bounds, by constantly pruning away the upper and better parts—a war of so-called Art against Nature struggling to be free. Mr. S. T. Wright, instead of further shortening these cramped Vines—mainly Gros Colmans—at the top, shortened them, so to say, at the bottom by drawing down the rods and bending them into excavations made in the border, affixing them firmly with stout pegs, packing fresh soil round them and keeping it moist. Thus 3 or 4 feet of head room was obtained for the best portion of the Vines, while the lower parts, which practically gave no fruit, were made to bristle with roots as shown in fig. 11, and from these in turn issued innumerable food-imbibing organs, the Vines responding by deeper green and stouter foliage, and freely swelling fruit. This is good, very good, and fuller effects will be seen next season than this, as the Vines were only "layered" early in the present year.

But now comes the point we wish to urge, and by which Chiswick, while proving by the best of all tests—crop values—the most excellent work, may, and should, be something very different from a market garden. If a few of these Vines had been left to struggle their way, and bear such crops as they could, and if these crops proved markedly inferior by comparison with the others wisely treated, then surely would the power of superior cultivation be impressed so firmly on the minds of inexperienced students as to never be forgotten; and further, if exact records were kept of the results of different methods, and these methods were carefully described, the published information would be of value far beyond the confines of the seat of such practical educational experiments.

Similarly, in the case of pruning the much older Vines in the much larger house, if a few of those Vines were allowed to carry an over-profusion of thin laterals and small leaves, and these laterals were closely spur-pruned, then would be seen by force of contrast the fallacy of such treatment, and the value of intelligent routine as represented by the far larger and more lucrative crop borne by contiguous Vines to which such routine had been applied. There are thousands of old and comparatively fruitless Vines almost all over the country that might be made to bear—as many have been made to bear—crops of fourfold value and more by a simple change in management, that costs no more than the old stereotyped rule-of-thumb method, which might have answered well when the Vines were young and the roots under the control of good cultivators.

Visitors to the gardens last week would see more Vines than those to which we have referred, including the high-sided span-roofed Muscat house, in which the Vines were not trained by Mr. Barron to the apex of the lofty roof, but horizontally across the house, a little above the base of the rafters. The result will soon be a golden ceiling of fruit. How much labour has been saved by this departure in dressing the Vines and thinning the Grapes it would not be easy to compute, while the Vines are in a great deal better state so far from the glass than are hundreds which are too near, or cruelly pressing against it. Most Vines are trained too near the roofs to which they are secured, and these Chiswick Vines tell us plainly that they suffer nothing by being

even some feet below the roof of the house; and their distance from it, in bringing the Grapes nearer, lends enchantment to the scene.

Passing from the Grapes in the course of inspection the substantial growth of Tomatoes in pots could not fail to be noticed — not sappy, flabby, luxuriant growth, but hard stems, with a minimum amount of pith in them, and leaves like cardboard. Why are Tomatoes, no matter what the varieties, nor whence the seeds come, invariably free from the "drooping" or other mysterious disease at Chiswick? Mainly because no mistakes are made in the treatment of the plants, though fungologists will scarcely be able to accept that reason. We have often wished that Mr. Barron had in his time purposely blundered, if he could, with some plants for "bringing on" the disease, as we have not the slightest doubt it has been brought on in hundreds of cases, though not in all, by errors in management; equally we should like to see Mr. S. T. Wright blunder also, with the same object, if he is capable of the task.

Dr. Masters, in his interesting address, which will be subsequently referred to, laid stress on the American practice of spraying for the prevention of fungoid attacks, and thought it might be tried at Chiswick. Dr. Plowright in response jocularly observed that after a search all through the gardens he "regretted" his inability to find any fungus to spray against. But if the resting spores of the "drooping disease" fungus lurk in the seeds, as seems to be the case, quicken and take possession of the plant germ, growing with the growth of the plant until this is overwhelmed, how is it that these fungus-bearing seeds fail to find their way to Chiswick? Seeds have come from nearly everywhere, but yet the plants are "clean." If Chiswick could "invite" the fungoid disease by ill-conditioned plants, and get the invitation accepted, it might teach a lesson of incalculable value.

A curious circumstance may be here related as bearing on the subject under notice. It may perhaps even be regarded as a "nut to crack" by some of our fungological friends. A small packet of Tomato seed was divided between Chiswick and a Tomato connoisseur. The Chiswick portion gave plants as healthy as plants could be. Every one of the gentleman's plants collapsed. They "looked queer from the first," his gardener said. Some of the miserables were examined by an "authority," whose verdict was "dirty seeds, fungus spores in them, bound to fail." The owner of the plants was of a different opinion. He saw all the seeds sown, as he thought much too thickly, and there was none to be examined. He found the young plants, after they had fairly started and looking well, one day quite sodden ed by, as he said an accident. They ceased growing, turned first a dark colour, then became mottled, and though the best was done to save them, they drooped and died. We wonder if such accidents ever happen at Chiswick. If they do, they should not be passed by in silence. The bad as well as the good should be noted there, and it would add to the instruction of the students and the public if there were something of both to note.

The desire to do all things well is a worthy aspiration, but a few blunders, and their results, such as in pruning for the production of wood and the prevention of fruit; in the non-thinning of fruit on an overladen tree or Vine, and in various other items of routine work in the several departments would afford object lessons which could not be ignored. Then what instructive themes would be afforded for lectures—which we think the Chiswick students should have from time to time—by scientific men; they can learn good practice from the superintendent. But it is feared that if the controlling power should decide to wait for the realisation of Dr. Masters' great conceptions before moving in the matter, it will only be the students of the distant future who will benefit by the teaching that he so laudably desires.

One other want of Chiswick—a very homely one, it is true, but if supplied would do more to improve the Gardens than anything else—is an extra generous supply of the best procurable manure, with as much good "holding" loam as could be obtained. The land has been overworked and underfed for years, and is getting poor and stale, especially the open vegetable and flower quarters. For fruit and Potatoes it may be rich enough, but for most other crops it is deficient in humus, and generally in a state that would drive a market gardener into the bankruptcy court. This is seen plainly enough in the Pea trials, where the land was well trenched.

Mr. Veitch thinks Chiswick is becoming too much of a town garden, and seems to favour emigration. True, it is the centre of a large population; but still, there does not seem to be much the matter with the forest trees around and the fruit trees in the garden, while it does not yet seem to be a struggle for life with the Roses. It is always well to look ahead and provide for the future; but as Chiswick in its structures has not been so well furnished

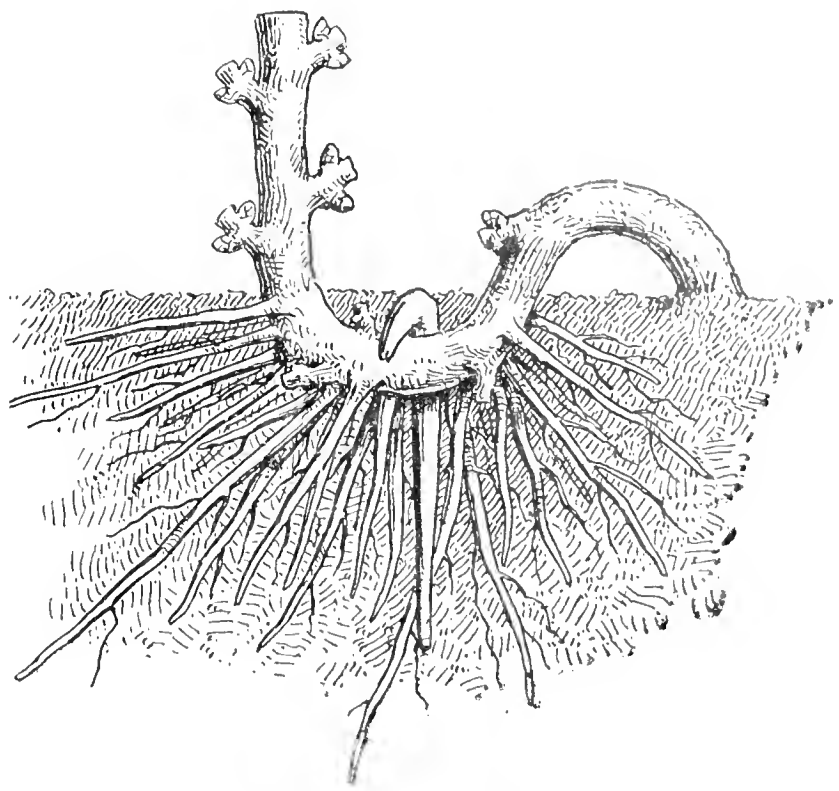

FIG. 11.—LAYERING OLD VINES.

before, and as the fertility of the soil can be increased, we suspect the cherished old garden will, under fair treatment, be capable of showing good results for several years to come.

Having entered somewhat fully, but by no means exhaustively, into the work, wants, and possibilities of Chiswick, as suggested by the first item in the programme, the other features may be dismissed more briefly.

THE LUNCHEON.

Provided in a large marquee on the lawn the repast was all that could be desired. We understood that 150 invitations were issued, and most of these must have been accepted. Sir Trevor Lawrence, Bart., presided, supported by Sir J. D. Hooker, F.R.S., and members of Council. Only one toast was proposed, "the Queen," and, as may be expected, it was accepted with unanimity.

The President then rose and gave to all a hearty welcome, expressing his pleasure that so many had been able to attend on the occasion. He desired to convey the Council's appreciation of the services of the different Committees, the members of which so willingly attended the several meetings for the sole object of aiding the Society to do all that could be done in the interests of horticulture. The Scientific, Plant, Orchid, and Fruit and Vegetable Committees did each in their sections work that could not be otherwise done so well, as the members possessed special qualifications, and some of them travelled long distances to discharge their duties without fear or favour. They gave their time freely, and not without cost to themselves, solely to advance the art in which all were interested, and in a spirit of good-will to the Royal Horticultural Society. The President's address and graceful references were accepted by the assembly in the same spirit that they were tendered, and this was of the best.

THE DISCUSSION.

"Dr. Masters, F.R.S., will open a discussion on Practical Suggestions for the Better Utilisation of Chiswick Gardens" was the announcement, and it brought together a large audience—at least,

all who attended the gardens appeared to be present. This is only what might have been expected, as not only is the Doctor a gentleman of distinguished scientific attainments, but the happy possessor of a charming disposition, and is one of the most popular men in the domain of horticulture.

An impression was prevalent prior to the meeting that an elaborate paper had been prepared to be read at the meeting; but this was not so, and the address was not the less acceptable because unconventional and, so to say, conversational, appearing to be based on a few jottings on a slip of paper and a couple of letters from America. What lecturers would do without America and its exhaustive "State" reports is not easy to conceive. They are wonderful productions truly, though we believe several of the best gardeners of the New World have "gone over" from the Old, and are still going. Let us hope it is a good thing for both—for the gardeners and for the great nation of the West.

In alluding to the Doctor's address we will follow his example, and make no attempt to give a formal report, but indicate the character of his observations in an unconventional way, and if the pen should be disposed to drop a comment here and there to let it have a run, regardless of consequences. First of all, and very appropriately, thanks were tendered to the Council of the Royal Horticultural Society for affording the opportunity for such a pleasant gathering of scientists and practicalists. The sundry responsive "hear, hears" suggested two things—1, that the Doctor had given expression to the feelings of his audience; 2, that the said audience would not object to anniversaries of the occasion. Wise audience.

We were then taken for a few moments to the "past" when "the area of the gardens was much greater than now, and their work wider in its scope; when plants were collected by Fortune and others, great and good work done in the fruit department by Robert Thompson, and meteorological observations carefully recorded." The pen seems to want to say certainly in the old days the weather records at Chiswick were looked for by many gardeners, and they would be welcome now if the same scrupulous accuracy in observation and presentation were forthcoming. The lecturer went on to note that "the times had changed, and Chiswick did not stand so much alone now as it did in the days of its ancient glory. Kew had become more and more active, more and more useful, and the enterprise of nurserymen and seedsmen was a great factor in the furnishing of gardens. The past, then, could not afford us much guidance now, and we must look to the present and the future."

As to the "present." Though we all know, and as the Doctor admitted, his inclinations are in the direction of scientific teaching, yet no one has a greater respect for and appreciates more the good work of practical gardeners than he does; and as he undoubtedly knows good work when he sees it, he "ventured to say that the gardeners present would agree that Chiswick was in excellent condition to-day, and a credit to its practical Superintendent, Mr. S. T. Wright, who was proving himself a worthy successor of a worthy man"—a remark that met with general acquiescence.

We were next asked to look to the "future." This was introduced by two questions—1, "Do we derive all the advantages we ought as a learned Society out of the garden at Chiswick?" 2, "Are we doing our duty to horticulture as well as it might be done in this matter?" These are significant questions worthy of serious thought. Evidently if the speaker had been pressed on the subject he would have answered both of them in the negative. And quite right, too, because if any body of men, however eminent, think they have gone as far as it is possible to go it is certain they will soon be left behind. Not for a moment is it implied that those who are responsible for the conduct of the Royal Horticultural Society are embued with any such feelings of self-sufficiency. If that were so they would not give facilities for and welcome suggestions for widening the usefulness of the gardens.

Dr. Masters has high aspirations, and he indicated what he would desire to see. "He would like Chiswick to be a great educational and instructional institution—a model garden, in which typical representatives could be seen of different kinds of vegetables, fruits, and flowers, with which varieties of the types could be compared." We suspect this is more easy to hope for than accomplish, even in the case of Cabbages, which were cited as examples. In the case of Peas well known standard varieties are grown this year, with which the new forms have been compared. Is not this of more practical service than having "types" merely—round-seeded white and blue, and of wrinkled types representing the different colours of ripened seeds, and so on with other things? It would be well to have good old standard varieties in all trials and invite improvers to excel them. Then the Doctor advocated "demonstrations in methods of cultivation, in pruning, training, trenching, mulching, and other routine work; also experimental trials, not with plants and crops only, but also of manures and with spraying, as in America, as well as of advertised remedies" which are supposed to make an end of all insects and plant and tree enemies. There is scope no doubt for carrying out at least some of those propositions, and more diversity might be displayed in the gardens both in cultivation and manipulative methods for educational purposes.

Passing to the Instructional section of his discourse, schools of horticulture naturally received attention. We have said before that in our opinion the best schools of horticulture (not botany) in the world are the best equipped and best managed private gardens of the United Kingdom, and from these have sprung the best gardeners on the face of the earth. It is all the same true that we have no experimental stations such as exist in America, and no properly equipped garden established for educational purposes in the various phases of horticulture, or in its utilitarian as well as its ornamental aspects.

We were told there are more than fifty State-aided experimental stations in America, and twenty of them of horticultural importance, conducted by practical and scientific men. Letters were read from two of the principals describing the good work conducted in those establishments, all the details of which are published for the benefit of the nation. One of the writers, with delightful modesty, gave an invitation to "send some wide-awake men over here to learn wisdom." They would no doubt meet with a welcome reception, see very much, and hear much more; but unfortunately we have none wide-awake enough to draw State aid from the British Government for supporting schools of horticulture.

Knowing this very well, the Doctor went on to suggest that "if we cannot have a fully equipped school at Chiswick, cannot arrangements be made for the students there to attend the lectures at Kew, whilst Kew students might in turn come to Chiswick to learn fruit and vegetable culture?" If any such arrangement could be effected the two sections of students would derive valuable instruction, which neither establishment can in itself afford. Kew is a magnificent institution, and has done splendid work for the empire, enriching the colonies by the Tea, Coffee, and other plantations, and in producing for home consumers greater and better and cheaper supplies of the necessities of life; yet Sir Joseph Hooker explained the great difficulty he had in obtaining the first £100 for scientific teaching at Kew, and he evidently foresaw difficulties in the way of the proposed amalgamation.

The Doctor's resources were, however, not exhausted as to the question of means. "There was the County Council. Could it not be induced to give monetary aid?" Middlesex benefits materially by its horticulture as practised in its market gardens and orchards; but we have not heard much of its county parliament doing much for horticulture. Derbyshire, Cheshire, Essex, Notts, Kent, Stafford, Surrey, Yorkshire, and other counties have made grants to scientific establishments and for practical work, while Middlesex has the most celebrated station of all within its confines, but its County Council as a body may not know it. Instead, then, of sending wide-awake men to America to gain "wisdom," let them go, with the Doctor at the head of them, to the headquarters of the Middlesex county authorities, and obtain a grant of £1000 a year for Chiswick, then will he add to his fame as a teacher of sciences that of a public benefactor in the horticultural world.

There could be no doubt about the speaker's earnestness of desire for sound systematic educational work, nor of the strength of his convictions that to be sound it must be scientific. He condensed his belief in the following pithy sentence:—"Brain work must be thrown into hand work, and practical subjects treated in a scientific way, as true progress could only be made when science was the basis of practice." Let all young gardeners write down that sentence, think it over till its full significance is comprehended, commit it to memory, act in accordance with it, and then may they in time to come benefit by this social and intellectual gathering at Chiswick.

The different speakers were listened to with great attention, the whole of them meeting with an excellent reception. This was

especially warm in the case of the wonderful octogenarian, with soldier-like carriage, bright eye, and strong clear voice, Sir Joseph Dalton Hooker of Kew, the grand old man of the botanico-horticultural world.

STRAWBERRY CULTURE.

Time of Planting.

The competition of present times demands that everything we take in hand must produce some result as quickly as possible. This remark applies with great force to Strawberry growing. No one likes to wait two seasons for a crop when, by a little extra attention, a good one may be secured ten months after the beds are planted. The secret of success in the whole matter is to start early with good plants as previously advised, and set them in their permanent positions during the first week in August. If this practice is followed with such early varieties as Laxton's No. 1, Noble, and Royal Sovereign, a warm position being chosen, ripe fruit will be obtained at least a week earlier than from two-year-old plants. From a market point of view this is, of course, an immense gain.

The next point to consider is the amount of space to be allowed for each plant. This must, to a great extent, be regulated by the nature of the soil and the length of time the bed is to remain before being destroyed. In light soils the early varieties are the most satisfactory if grown on the one-year system. The rows should then be 30 inches apart, and the plants 18 inches in the rows, each being kept to a single crown. This allows a good amount of vacant space between the plants, so that the warm sunshine of spring acting upon it induces early fruitfulness, a point which cannot be too strongly impressed upon the minds of all who strive to obtain early crops.

Early this season I called on a market grower noted for his early crops of Strawberries; he was at the time picking fine fruits of Noble, which were in great demand. I noticed at once that his young plants had plenty of space between them; but, curiously enough, he remarked in the course of conversation that he thought he would set his plants a little closer this year, as he hoped by so doing to get a still heavier crop. I at once told him that he would make a great mistake if he did, for although he might get a heavier crop it would not be so profitable, as thin planting and young plants were the two reasons why he placed his fruit on the market slightly before his neighbours; and I added, Plant closely so that the leaves of the plants almost cover the ground, and you will be no longer noted for early Strawberries. He was convinced at once, and will keep to his well-tried distances in the future.

Midseason and late varieties do not require so much space, as, of course, the object of the cultivator is not to get them early, but to secure heavy crops extending over as long a period as possible. Yet these are often planted too closely in gardens where the soil is very rich, through having been highly cultivated for years. In such instances 3 feet between the rows, the plants being set 2 feet asunder, is not too much. For field culture, and in moderately rich or light garden soils, plant in rows 30 inches apart, and 24 inches in the rows.

Planting.

After having been deeply dug and allowed to dry upon the surface, heavy soils will need little additional preparation; the little required is to reduce lumps to moderately small pieces with the hoe and make the surface of the bed uniformly level. Light soils should, however, be made firm by treading or rolling, so as to induce both roots and leaves to make short sturdy growth. If planted in loose soil the young plants make wonderful progress in the early stages, at the expense of fruitfulness at the critical time.

Good and careful planting is essential to success. Home-raised plants may often be lifted with a good ball of earth attached, then if care is taken to have the soil in a moist condition when lifting takes place, the plants scarcely feel any check from being transplanted. Plants turned out of small pots should have the roots disentangled and spread out in an even manner, so that every rootlet may be in a position to take hold of the new soil as quickly as possible. When the stock of plants is obtained from a distance there is, of course, practically no soil attached to the roots. In such instances proper or improper planting exercises a marked influence upon the future progress of them.

Sufficiently large holes should be dug with a trowel to allow the roots to be spread out evenly in all directions. When this is done the soil should be placed upon them, and be pressed or trodden firmly, or very firmly, according to the nature of the mould. The crown of each plant ought to be just above the surface of the soil, but the neck or collar must be covered.

After giving the plants a good watering mulch the ground with short manure, then, except in the case of prolonged drought, additional waterings will not be needed, but syringing on bright afternoons for a few days will greatly benefit the plants. Throughout the autumn and in early spring all runners must be persistently removed, so as to concentrate the energies of the plant in a single crown, as plump well ripened crowns thinly disposed are the delight of the experienced Strawberry grower, as they indicate the same promising state of affairs as do fruit trees bristling with buds, around which light and air have been allowed to perform their important work.—Pomona.

(To be continued.)

PRECEPT AND PRACTICE.

"The Amenities of Life."

(*Continued from page* 3.)

The transition from serving to ruling—from a subordinate position to that of a head gardener—however long it may have been anticipated, however seriously it may have been contemplated, brings one at a bound under the full fire of criticism, and, according to circumstances, within the pale of social laws hitherto but vaguely defined. Happy the young man who is prepared for such things. Classing bothy manners as a few that are good, more that are bad, and the bulk of which may be termed indifferent, the first we would retain, the next eliminate, and with the latter, the largest class, endeavour to feel the necessity of moulding them for use and adornment in the new position.

Here and there, in all phases of life, towers up some ragged character whose genius gives a license that few dare usurp; and in our own vocation are possibly to be found men of high ability and sterling merit who are known as "rough diamonds," who shine in barbaric splendour, free from that polish which would so greatly enhance their gifts. Politeness is a garment which shows to incalculable advantage upon the shoulders of youth, and superior judgment will award to the young wearer many marks towards the prize he seeks. It is not entirely a case of conversation or of correspondence, of dress and address, or of those little penalties exacted from all who form the links of a social circle; but it includes those nicer distinctions which on the one hand elevate a man above the commonplace, and on the other tone down that natural exultation attendant upon success, showing the possession of a well-balanced mind not swayed by every breeze of fortune, good or ill.

I have one example in my mind's eye of a head gardener who appeared to my youthful vision as an Admirable Crichton in his conformation to the amenities of life. His station of success was doubtless reached by two particular lines of conduct. The one of "scientific and practical competency;" the other by a clear understanding and due regard of our subject. As manners, good or bad, are decidedly contagious, and in no simpler way could much that the subject includes be more clearly conveyed, a brief biographical sketch of an honoured master may be given here.

He was a self-made man who, by sound judgment and sheer industry, overcame all obstacles in the race; his early life, indeed, being little less than an obstacle race. Native of a particular county, where, amongst the class from which he sprang, the Queen's English—"as she is spoke"—is all but unintelligible outside a given area, an indefatigable zeal to overcome what was early felt to be a serious disadvantage resulted in his becoming a veritable purist in conversation, whilst the same means, judging from various letters I, as a young man, was privileged to receive from him, showed that in the art of polite letter writing he was *facile princeps*. At any social function, where his services were required, a dignified demeanour with some practical knowledge of those duties, how acquired I know not, brought him through the ordeal with honours gracefully worn.

There is nothing, I believe, better calculated to self-advancement generally, or more conducive to self-reliance than public writing, and it is gratifying to find such excellent work telling its own tale in the "Young Gardeners' Domain." These young teachers and exponents of the art must, I think, take life as it should be taken, seriously. It would be well if every bothy in the kingdom took a keen interest in that privileged corner, and it is no disparagement to those whose practical pens are in evidence to say it would be equally gratifying to find its sphere enlarged by learners as well as teachers, to seek knowledge without diffidence, and to court criticism without fear.

Conversation in the bothy is not always of the most edifying kind, apart from the vernacular of those distressing dialects which

it behoves everyone who aspires to the higher ranks of our vocation in life to prune off, and engraft upon a stock, which surely is worth it, the elegant growth of our mother tongue. "Self-sufficiency" we have to be warned against; it is probably the most insidious and subtle enemy young life has to contend with. I do not think that any earnest student who seeks for truth beneath the surface of things will be its victim; it is rather with those who in skimming off a few showy superficialities to flaunt in their immediate circle are afflicted by this blight.

I now look back with disgust upon a period of life in which this sickness of self-satisfaction, with all its concomitant evils, infected me, and it affords unqualified pleasure in noting here and there some young gardeners who are apparently proof against the malady. Some few cases there are, however, observable which cannot but claim the sympathy we may award to them in noting how seriously they interfere with a due regard to the amenities of life, apart from which the patient must seriously suffer in mind, body, or estate. Ah! young Mr. Self-sufficient, "When next you talk of what you view, think others see as well as you."—AN OLD BOY.

(To be concluded.)

CYCLAMEN NOTES.

THERE is no flowering plant with which I am acquainted that will last so long in perfection as Cyclamen persicum, and produce such a succession of beautiful flowers of all shades of colours, useful alike for the embellishment of the greenhouse and conservatory and for cutting purposes. The marbled foliage, too, of these plants is pleasing, and some of the varieties are sweetly scented. Few plants are more easily grown or better repay good culture, and the enormous quantities now grown for market indicate the popularity of the Cyclamen.

Good well-flowered specimens may easily be grown in from twelve to fifteen months. The seed should be sown about the second week in August, in pans or 6-inch pots. I prefer the latter, using a compost of two parts leaf soil to one part of loam, with abundance of silver sand added. The seed should be sown thinly and covered slightly with fine soil. Place the pots on a shelf in a house the temperature of which is kept at about 60° to 75°. It is a good plan to place a sheet of glass over the seeds, and on this some moss or pieces of brown paper, which should be kept frequently moistened, thus preventing the soil from becoming dry. As soon as the seedlings appear the coverings must be removed, and the plants shaded from bright sunshine. When they show the second leaf it is the right time to pot singly in thumb pots, keeping them on a light shelf in a cool temperature all winter.

By February or March they should be in a fit state to be removed into the flowering pots—viz., 6-inch. Place them in a heated pit which has a good bottom of coal ashes on which to stand the plants within 2 inches of the glass. Keep the structure close for a few days, with occasional syringings. If the plants are well watered when potted they will require no more for some days, until the new roots are working into the soil, the moisture received through the daily syringings being sufficient to prevent their flagging. Keep the plants shaded from the hot sun at all times, and when well established take care that sufficient air is admitted on all favourable occasions, also leaving the lights off at night when fine weather prevails, as I have noted they are very partial to the night dews. The fire heat should also be turned off from this time onwards.

The compost recommended for sowing the seeds will also answer admirably for potting the young plants, but one part of sifted horse droppings (spent Mushroom bed) and some broken charcoal should be added. By the middle of September the plants will be growing luxuriantly, and will commence throwing up quantities of flowers. These may be pulled out if the plants are not wanted in bloom until later. Cyclamens are much benefited by frequent applications of liquid manure and soot water, which should be given alternately throughout the summer months. A little assistance in this respect is also beneficial at intervals after they are housed.

Those who require plants in small pots for the purposes of room or dinner-table decoration will find the Cyclamen answer admirably. A number of seedlings may be established in thumbs, and there remain until wanted for use, attending carefully to watering, and also feeding them rather highly. They will be found when turned out and mossed up of immense value, and have a very pretty effect. They will bloom freely, each plant carrying as many as two dozen fully expanded flowers at one time. It is advisable when potting these to select only two or three colours which are most appropriate to the requirements of the establishment.—H. T. M., *Stoneleigh.*

ORCHIDS AT MERE BANK, LISCARD.

AT his charming residence on the Cheshire shore of the Mersey the collection of Orchids brought together by the well-known enthusiast, D. B. Rappart, Esq., is noted for its quality rather than quantity. A recent introduction to the above gentleman led to a most enjoyable visit being paid, when I had the privilege of seeing many choice plants of Cattleya Mossiæ in flower. A fine piece of C. Mossiæ alba was pointed out, and some excellent C. Mendeli, Cattleyas Skinneri and superba, Cypripedium caudatum Wallisi, and the seldom seen Dendrobium rhodostoma. Overhead Cattleya aurea was in the most vigorous growth such as one rarely meets with, giving every promise of a charming feast later on. The Trianæ section is well represented, containing C. Trianæ alba and C. Trianæ Backhousiana. C. Gaskelliana is seen in abundance, and I hope, by the kind permission of Mr. Rappart, to send a bloom of the true C. Gaskelliana alba, which is now in sheath.

The white forms of Cattleya Skinneri are noticeable, and C. intermedia alba Parthenia is represented by a fine strong plant. The rare Lælia elegans blenheimense is doing well, as also are L. anceps in variety and L. majalis, growing on an old Dicksonia stem. Rich as are the varieties of Cattleyas, not less so are the Dendrobiums of the varieties barbatum, Schneiderianum, Amesiæ (strong), nobile album, n. nobilius, Backhousiana, Juno, Luna, Venus, Cypheri, albiflorum, and Apollo grandiflorum. The cool house Orchids are not quite so satisfactory, and Mr. Rappart takes rather a gloomy view of their ever doing well, thinking their situation rather low; but I am more sanguine, believing, as I do, that his new gardener, Mr. A. H. Nicholson (a young pupil of Mr. Barberry's), will work in the right groove, although I am well aware that no class of Orchids are so difficult to pull round when they have once gone back as the cool house section. Odontoglossums cordatum and crispum and a grand form of O. Uro-Skinneri were in bloom. Naturally, hybridising is made a prominent feature, seed pods being in abundance and the crosses choice.—R. P. R.

DENDROCHILUMS.

ALTHOUGH the correct name of this genus is Platyclinis, it is usual among Orchid growers to call them by the older name instead of that given by Bentham to part of Blume's original genus. I am not aware if any of the true Dendrochilums are now in cultivation, and if not it is perhaps the wisest course for orchidists to pursue. The plants are dwarf-growing pseudo-bulbous epiphytes of an evergreen character, at least under cultivation. The genus is not a widely distributed one geographically, chiefly occurring in the Malay Archipelago, Java, and the Phillipine Islands. They form beautiful objects when well grown and flowered, especially large specimens.

The natural habitat suggests the best temperature for them, that is the East Indian house. A brisk moist heat with all the light and sun possible, without injuring the foliage, they delight in, the moisture keeping insects at bay, and the quickened temperature causing the little pseudo-bulbs to swell to their fullest extent and to bloom freely. They cannot, in fact, do the one without the other, for if only ordinary care is taken with large healthy bulbs they are sure to produce a bounteous crop of blossom. In this, as many readers are aware, they differ from Dendrobiums and one or two other genera.

This strong moist heat must be continued as long as growth is active and until the pseudo-bulbs are well swelled out, and must be accompanied by abundant root moisture. Being quite finished and ripened a slight diminution must be made, and all through the autumn and early winter, if the roots are moistened when they begin to get on the dry side, the plants will take no harm. Dry rest, as the term is understood, is not required; on the other hand it is injurious, leading to shrivelling of the pseudo-bulbs and general weakness of the plant. But a natural rest, brought about by slightly lowering the temperature and decreasing the atmospheric and root moisture in a like ratio, is recuperative and helpful to the plants.

In early spring the flower spikes usually appear, and as soon as these can be distinctly seen the temperature may rise a little and the roots be kept rather more moist. They take some time to come to perfection, but on well grown plants are little trouble. When fully developed the plants may be taken for a few weeks to

a cooler and drier house, and have a very fine effect suspended from the roof. By the time these spikes are over there will often be signs of new growth from the base, and this is as good a time as any for propagation or renewal of the compost.

Large plants may, if necessary, be cut up into as many pieces as there are leads, first removing as much of the compost as can be got at conveniently, so that a few roots may be secured with each divided portion. Not that these are of any great value to the plant except as a means of mechanical support, for what is of much more importance is to secure the young roots that are put forth after these bits are separately potted. Get these to take a good hold of the new compost at once, and the future health of the plant is practically secured, but if through mismanagement these are lost it will be far from a healthy or thriving plant for years.

A very thin layer of compost will be found sufficient for these little pieces, the pots or pans used being then partly filled with crocks. The best material is peat fibre and sphagnum moss in equal proportions, with abundance of finely broken crocks and charcoal to insure a free passage for air and water. In repotting plants that have not to be divided let the drainage be thorough, as large quantities of water have to pass it, and in removing the plant from the old material be careful not to disturb the roots unduly. In finishing the line of compost let it form a very slightly convex surface, and just finish under the base of the last formed pseudo-bulb.

Both small and large plants must be carefully watered for some time after being disturbed, any excess causing both old and young roots to decay. Rather more shade also may be allowed for a time, and the house wherein they are grown kept fairly close. The most generally cultivated species is D. glumaceum, a very elegant and beautiful Orchid, a native of the Philippine Islands, where it was discovered, along with D. filiforme, by Cuming, and sent to Messrs. Loddiges of Hackney. It first flowered at their nursery in 1841, and a little later in the same year D. filiforme flowered in Mr. Bateman's then famous collection. The racemes of the former species are creamy white when fully developed, those of the latter bright golden yellow. Paler in colour, but of the same graceful habit, is D. Cobbianum, named after the gentleman with whom it first flowered in England—Mr. Cobb, of Sydenham. This was sent home in 1879, and flowered in August and September. D. uncatum is a pretty plant with shorter stouter racemes of pale greenish blossoms, produced very early in the new year.—H. R. R.

LILIUM CANDIDUM.

I NOTICE in last week's Journal one of those complaints which are constantly being made with regard to the failure of this old and beautiful favourite of our gardens. I am somewhat surprised at this, although the writer does not give any information as to the locality or soil. I have never in my experience of it seen it in greater luxuriance or beauty than it is this year. I have clumps of it which are a mass of flower, and this is more especially to be noted, because in one place in my garden they nearly all perished a few years ago. I attributed this to the Lily mite, and conclude that some small bulbs were left which have increased in size and vigour, and have this year bloomed. I did not disturb the soil, because in the bed in which they were planted there were Orange Lilies as well.

I have recently been through different parts of my parish, and wherever I have gone I have seen this Lily in the greatest luxuriance. There are some labourers' cottages on a sloping bank facing the south, where the soil is sandy, and altogether about as hot a spot as they could well be in, and here the gardens were quite a show, so strong and luxuriant were the plants. In another garden on the top of the hill, still facing south, they are equally vigorous, while I saw in a border to a drive leading up to a house, a large quantity of them in full flower.

I have also seen them in situations somewhat different from these, where they seem to be doing well; but I have come to the conclusion that a hot and dry situation is what suits them best. It may be asked whether these have had any special cultivation. My reply is, Certainly not; they have never been touched, and I believe this is one reason why they have done so well. Many Lilies resent disturbance, some more than others, and I think that candidum is one of those that least like it. When the bulbs get too much crowded together it may be well to take out some without disturbing the clump, so as to give room for the others to increase in size.

While writing of white Lilies I may mention a new one which I have in flower in my greenhouse, Lilium philippinense. I do not think it is quite ascertained to be hardy; it comes, as its name implies, from the Philippine Islands, and would, therefore, probably be considered as tender, but as it is found in the high altitude it may be like some of those plants from Kilemanjaro, situated almost on the Equator, which can yet bear open-air culture in our climate. It is dwarf in habit, with a long slender tube-shaped flower somewhat in the style of longiflorum but more slender, about a foot in length, with a pleasant fragrance. It is a very elegant and attractive Lily, and, so far as I can see, seems of easy culture, and will, I have no doubt when plentiful, be very popular. —D., *Deal*.

CROSSING AND SPOILING MELONS.

I DO not know how it is that Melons of the present day are such a medley and uncertain in quality lot. Very few have any merit beyond appearance, and scarcely any receive recognition from the Fruit Committee of the Royal Horticultural Society. I have only sent two in my time, and the Secretary wrote, saying "they were not superior to those in cultivation." Well, I was rather dumbfounded over this, as they were certainly more esteemed at home than any named varieties, and in Covent Garden Market brought 1s. more per fruit. In sending seeds to various growers I got invariably two replies—1, Extremely difficult to grow, and not of superior quality, which meant that Melons varied considerably in different soils and under diverse treatment. 2, Not two plants alike in growth, and the fruit even variable on the same plant; some oval, others spherical; some smooth, others netted; some ribbed, with others without ribs; some scarlet-flesh, others green or white, with some both scarlet and green or white, or all three mingled in the same fruit; some sweet, and others poor in flavour. Here again I had either sent the wrong sort or the varieties were wholly unreliable—a mongrel, wastrel lot.

The whole thing passed my comprehension, as with me the varieties grew like weeds, were always the same, never getting mixed, and invariably pronounced very good. Not being in the "pink of perfection" when cut by the Royal Horticultural Fruit Committee's knife, I can readily understand, and of their appreciative appetites I entertain no doubt, even when they do not agree to give a recognition of merit. That the Committee know a good Melon there is no question, and perhaps some of the members are old enough to remember Early Cantaloupe, Egyptian, Persian, and Cabul—the only four sorts grown in the garden where I first had anything to with Melons. If so, they will remember how true they were to type, and were grown from year to year without change of flesh by any process of crossing by natural or artificial means. There was the scarlet-flesh, green-flesh, and white-flesh, in their order, perfect—not a better Melon now—at least, I never taste their equal, if palate-memory tell truly; hence I have come to the conclusion, rightly or wrongly, that Melons have been "crossed and spoiled."

There are several types of Melons. Naudin makes ten groups of them, nine of which are concerned with the cultivated forms:—

1, Cantaloupes (Cucumis Melo var. cantaloupensis).—The name is derived from Cantaluppi, a former seat of the Pope near Rome, where the Cantaloupe Melons were early brought from Armenia. The fruits are characterised by a hard and more or less warty, scaly, or rough skin, and they are often deeply furrowed or grooved, the appearance belying their good qualities.

2, Netted (Cucumis Melo var. reticulatus).—This class comprises the greater part of the Melons now grown in this country. Some are ribbed (of Egyptian origin), others smooth, barring the netting (of Persian origin). All are very juicy fruits, very tender, somewhat watery, and thin rinded.

3, Sugar (Cucumis Melo var. saccharinus).—The Sugar Melons are small, hard rinded (Turner's Scarlet-flesh) or medium in that respect (Pine Apple), very firm, solid, melting flesh, deliciously flavoured. Some are ribbed, others smooth barring netting. They are merely forms of the netted or Nutmeg Melons, as highly concentrated a flesh and quality as it is perhaps possible to get Melons, and this may be where the spoiling begun—the endeavour to get the firm flesh into the soft, scarlet into green flesh, and neither one thing nor the other, as soft flesh ripens before the hard, and the scarlet mingle with the green.

4, Scentless (Cucumis Melo var. inodora).—This class comprises the long-keeping or Winter Melons, smooth or nearly so, large and oval. They are of very inferior quality, and probably of Central Asian origin. The fruits are different from the long-keeping Cabul Melons, the latter being exquisite, and certainly of similar type to the Persian.

5, Snake (Cucumis Melo var. flexuosus).—A snake-like fruit, more like a Cucumber than Melon, and of no use. The fruit is greenish yellow at maturity, and longitudinally ribbed. The fruit is sometimes preserved and considered fine. It must not be confounded with the Snake Cucumber (Cucumis lagenaria).

6, Cucumber (Cucumis Melo var. acidulus).—The fruits are more or less cylindrical or oblong, variously mottled or unicoloured.

This is probably the type parent of the Persian Melons, and a native of India.

7, Dudaim (Cucumis Melo var. Dudaim).—Fruit about the size of a small Orange, flattened like one at the ends, very regular in form, and beautifully marked with longitudinal bands of yellow, interposed with marbling of cinnamon-brown. The handsomest Melon and the most powerfully scented, a single fruit scenting a large room. There it ends, as the fruit is not edible. It is the well-known Queen Anne's Pocket Melon.

8, Chito (Cucumis Melo var. Chito).—This is the Orange or Lemon Melon, as the shape or colour may be, without markings and next to no odour. Its flesh is white or pale yellow, and about as useless as that of a ripe Cucumber.

9, Red Persian (Cucumis Melo var. erythraceus).—The true Persian, or rather red type; fruit long, somewhat intermediate in form between a knobby-ended Cucumber and a Vegetable Marrow. Whether the green and white are mere forms I cannot gather from Naudin, but there are manifestly only three distinct types, and all originated in India or adjacent parts of Asia.

The Cantaloupes were early in the century distinguished as Early, Netted, and Rock, and out of these issued the Nutmeg and Sugar forms. Egyptian may have only been a form of Cantaloupe, but crossed with Persian we get Egyptian from Cantaloupe without so much rib, and following it up get out of ribs altogether. In reverse order Egyptian or Persian give the ribs back again, and so we might go on indefinitely until we come to but three forms—(1) Cantaloupe, (2) Egyptian, and (3) Persian.

That is all I can make out in British Melons, and they have been so crossed and intercrossed as to be scarcely distinguishable, while some are all three in one, and as variable as the generations. Hence neither the Royal Horticultural Society's Fruit Committee nor anybody else can find anything distinct about Melons, one taste or quality militating against the other, and they escape doing anything, as the fruit is wholly divided against itself.

Surely it is high time that distinctness should be a decisive aim in Melon crossing, keeping as near to type and as far as possible seeking to have fruit of as clearly defined character as practicable. The whole system of crossing seems to be running riot in other fruits as well as Melons, and certainly not for the better, but worse in some cases. What present day Melon has the quality of Turner's Scarlet Flesh? In which is the juiciness and lusciousness of Egyptian? And where may be found the delicate flesh and agreeable taste without after-coming of the old white-fleshed Persian?—G. ABBEY.

VEITCH MEDALLISTS OF 1897.

THE following awards of Medals of Honour have been made by the Veitch Trustees. Circumstances have this year prevented the attendance of the recipients in person, and the medals have accordingly been sent to them.

NORMAN C. COOKSON in recognition of his great success in the hybridisation of Orchids. Among the earlier acquisitions, mention may be made of Cypripedium Io, C. Godseffianum, C. nitidissimum, and C. Sanderæ superbiens, still highly appreciated. Besides these, some of the finest hybrid Cypripediums obtained by other operators as C. Calypso, C. Morganiæ, C. cardinale, C. Niobe, have been raised by him from the same pairs of species, and have very properly received the same names. In other genera he has obtained Calanthe Cooksoni, Cattleya William Murray, Lælio-Cattleya Phœbe, Dendrobium Venus, D. Owenianum, Masdevallia Courtauldiana, all hybrids of great merit. With these may be grouped Phaius Cooksoni, a plant of exceptional interest, on account of its being the first hybrid Phaius in which the remarkable Madagascar species P. tuberculatus has participated in the parentage. Among later acquisitions Cypripedium Bryani, Lælio-Cattleya Doris, Dendrobium Sybil, and Phaius Cooksoniæ, are beautiful hybrids, but especial prominence must be given to Odontoglossum crispo-Halli, one of the most remarkable of artificially raised Odontoglots; and scarcely less interesting is the confirmation of the supposed parentage of Cattleya Hardyana. The hybrids raised by Mr. Cookson include a large range of subjects, and will bear enduring testimony of his horticultural skill.

MARTIN R. SMITH, in recognition of his great success in improving the garden Carnation. This success is the more remarkable from the fact that when Mr. Smith took up the subject he began to work in a field in which great results had been already obtained, especially by the late Charles Turner and Ephraim Dodwell, besides other cultivators of this popular flower, when further improvement seemed well nigh unattainable. It is well known among amateurs of the Carnation that of the numerous seedlings raised annually very few retain a permanent place in collections. A glance through the groups into which florists have distributed the different forms and colours shows that some of Mr. Smith's seedlings possess qualities that will make them exceptions to the general rule, especially in the group known as Malmaison Carnations. In this group Mr. Smith's acquisitions are particularly valuable, not only to amateurs, but to horticulturists generally.

CHARLES NAUDIN, for distinguished services to botany and horticulture. He is one of the most eminent French botanists of the present time, and has been for upwards of thirty years a member of the Académie des Sciences, the most important scientific body in France. He began his scientific career in the Jardin des Plantes, where he soon gained distinction by his accurate investigation of the subjects submitted to him. Among these were numerous experiments to determine the nature and validity of species, including the determination of the many cultivated varieties of the Gourd and Pumpkin. By carefully growing the numerous kinds side by side, by comparing one with the other, and by crossing or attempting to cross one with the other, he eventually succeeded in tracing all the edible and most of the ornamental forms to Cucurbita Pepo, C. maxima, and C. moschata. While connected with the Jardin des Plantes, he collaborated with Professor Decaisne a general treatise on horticulture, entitled "Manuel de l'Amateur des Jardins," still the most scientific and best illustrated work on gardening in the French language. Failing health obliging him to leave the Jardin des Plantes about the year 1870 after passing some years in experimental horticulture at Collioures, he accepted the directorship of the Villa Thuret garden, established by M. Gustav Thuret and Dr. Bornet at Antibes, as a botanic garden for experiments in the acclimatisation of subtropical plants. The villa and garden are now the property of the French Government, and form a sort of southern branch of the Jardin des Plantes, under the direction of M. Naudin, in which are cultivated Australian, South African, and many other subtropical plants, for distribution among the French colonies, and for the use of the Universities of France. Since his instalment at the Villa Thuret, M. Naudin has published a valuable "Manuel de l'Acclimateur," in which the author's extensive knowledge of the large and difficult genera Acacia and Eucalyptus is conspicuously shown.

MAX. LEICHTLIN, in recognition of eminent services to borticulture, especially the introduction of many new and beautiful plants. Max. Leichtlin occupies a unique place among the horticulturists of the present day. Apprenticed to a gardener in his youth, he subsequently held situations in several places, but finally settled down at Baden-Baden, where he founded a private Botanic Garden, which has since become a household word wherever rare and beautiful species of bulbous and perennial herbaceous plants are prized. In this remarkable garden, scarcely half an acre in extent, Max. Leichtlin has worked for upwards of forty years, with the assistance of only one or two skilled labourers. During this period, remote corners of the earth have been searched for plant rarities; and when once these treasures have found a home in the little garden at Baden-Baden, the skill of the owner has rarely failed to make them available for the gardens of Europe.

To enumerate the many plants introduced by Max. Leichtlin would require a very large page of letter-press; but to show how cosmopolitan his operations have been, a few representative instances should be noted. Thus, among his introductions we have Anemone blanda from Armenia, Colchicum Szwowitzi from Persia, Bomaria oligantha from Colombia (S. America), Calochortus Leichtlini from California, Eremurus robustus and Ostrowskya magnifica from Central Asia, this last the grandest of all Bell-flowers; Galanthus Reginæ Olgæ from Greece, Gladiolus platyphyllus and other species of Gladiolus from South Africa, Kniphofia comosa from Abyssinia, Leucocoryne purpurea from Chili, Meconopsis racemosa from China, Olearia insignis from New Zealand, Tigridia Van Houttei from Mexico, and many more, forming a surprising record for one man. Besides all these, many beautiful forms have been raised in the Baden-Baden garden by hybridisation and selection, as the Kniphofia hybrids, Pæonia Moutan varieties, Clematis coccinea major, Crocosma aurea imperialis, Aubrietia deltoidea Leichtlini, and many more.

The plan adopted for the cultivation of so large a number of species within so small a space is a very simple one. As soon as new plants and bulbs have been proved and multiplied, they are distributed among the gardens of the world, and room is made for new introductions. Novelty and change are the predominant features of the Baden-Baden garden; the occupants of it at one epoch disappear within a short period afterwards.

Professor L. H. BAILEY, for eminent services to horticulture. As Professor of Horticulture in the Cornell University in the State of New York, Mr. Bailey has laboured earnestly to promote the science and practice of horticulture in the United State in various directions. This he has done primarily by lectures, in which he has brought before his audiences, usually consisting of farmers and others engaged in the manual work of cultivation, the more important facts in plant physiology, which are apt to be overlooked by ordinary workers, besides other illustrations of plant life, some knowledge of which is indispensable to those engaged in gardening and agriculture. He has done essentially good work in teaching and illustrating the use of insecticides in investigating the origin of plant diseases, and experimenting on the means of arresting them, especially in fruit trees, in which he has rendered valuable service to the fruit growers of America. He is one of the most prolific writers on applied botany in the United States; the numerous year books on horticulture, and the useful bulletins issued by the Agricultural Station connected with the Cornell University, bear ample testimony to his great activity in disseminating useful knowledge, whether derived immediately from his own observations and experiments, or from the publications of others. He has published several important scientific works, among the latest of which is one entitled "The Survival of the Unlike," a collection of evolution essays, suggested by the study of domesticated plants.—("Gardener's Chronicle.")

ROSES

ROSE SHOW FIXTURES FOR 1897.

July 22nd (Thursday).—Halifax, Trentham, and Bedale.
„ 23rd (Friday).—Ulverstone.
„ 27th (Tuesday).—Tibshelf.
„ 28th (Wednesday).—Chester.*
„ 31st (Saturday).—Liverpool.*

* Shows lasting two days.

MEDEA AND MARÉCHAL NIEL.

I CANNOT suppose that there really exists much difference between "W. R. Raillem" and myself regarding the respective merits of Medea and Maréchal Niel. I was not thinking much of Roses for the conservatory (of which the Maréchal is unquestionably the king) when I wrote the article to which your versatile correspondent refers, but of Roses adapted for open air cultivation. I quite admit that of the two varieties Maréchal Niel has the deeper hue and, when fully expanded, the finer formation. But Medea is also a very impressive Rose. Here it has been of beautiful colour and of immense substance. It has, in addition to its distinctive beauty, the great merit of perpetuality. Maréchal Niel is not adapted, in Scotland at least, for garden cultivation. It is, on the other hand, a superb Rose for the conservatory, in which, as I have indicated, it reigns supreme.—DAVID R. WILLIAMSON.

COMMENTS.

THE Jubilee celebrations altered many things this year, and for the first time since the National Rose Society went to the Crystal Palace, the show was not held on a Saturday. To many of us this was a great boon, for as the parsonic element is very strong in the Society, the alteration of the day to Friday enabled them to get off comfortably home and have a day's rest before the Sunday; it added moreover to the comfort of the exhibitors and visitors, for as there was not anything like the number of people that there is on Saturday, locomotion was more easy, and many people said they enjoyed the Roses better than they had done previously. There was, however, this disadvantage, that there having been a promenade concert and fireworks the night before, the officials did not begin the arrangements for the show until 10 30, so that the whole had a very unfinished appearance.

The Show was held in the centre transept, opposite the great organ, and in the concert room—the latter a most inappropriate place. The day was dull though fine, and the consequence was that the Roses in this part of the exhibition did not show at all to advantage, and many a growl came from amateur exhibitors against the obscurity in which their fine flowers were placed. The complaint was a just one, but unfortunately the Society has no choice in the matter. Either the amateurs or professionals should be relegated to the concert room, and should the show be held next year in the same place the conditions must be reversed, and the concert room be assigned to the professionals.

I have attended all metropolitan exhibitions held by the Society, and I can safely say, according to my judgment, it was, as far as the quality of the flowers was concerned, the best that we have ever had. Mr. Mawley has already said how extensive it was, and how the English counties contributed towards it. Scotland was unrepresented, and, of course, we cannot call Messrs. A. Dickson & Sons of Newtownards Irish exhibitors pure and simple. One object they had, I believe, in taking up the old classic ground occupied by Mr. W. J. Grant at Ledbury, was that they might compete more favourably at the early English shows. The prize list gave ample evidence of the extent and excellence of the exhibition, for there were only two classes in which all the prizes were not awarded, and these were the garden Roses. This will of course tell heavily on the finances of the Society, for there have sometimes been upwards of £20 not awarded.

An attempt was made to connect the show with the Jubilee by having a special class for table decorations. In my judgment this was a failure. Roses, even under the practised hand of Mrs. Orpen, are very difficult to arrange, and although her arrangement was tasteful and she did the best that she could, yet one felt how much better she would have done had she been able to introduce other flowers. In regard to the vases of Roses there could be but one opinion as to which merited the first place, and the vase which was placed third would undoubtedly have been second but for for some unfortunately heavy grass which was introduced and entirely marred the lightness of the arrangement.

Another very pleasing feature about the exhibition was the considerable accession of new exhibitors; for while one is always ready to welcome the old practised hands, which have for so many years contributed to the success of our shows, the addition of new blood affords a surer guarantee for the future welfare of the Society. Looking back we cannot but feel how much we miss such names as Baker, Jowett, Hall, and Whitwell, and are, therefore, thankful when we find fresh names amongst our lists of prizewinners; and in looking through the lists of this show we find many who even at their first attempt have carried off honours. This is, no doubt, to be attributed in large measure to a system adopted on the initiative of Mr. Charles J. Grahame of classifying exhibitors according to the number of plants grown. Had the old system still been in vogue these persons would have been deterred by the feeling that they had to come into competition with growers who had big battalions to draw from, and had, therefore, of course, a greater chance of success on the show day. At the time this was proposed I very much doubted its wisdom, but I have for some time seen that the promoters of it were quite right.

This exhibition showed another great change, I mean in stands for new Roses. Formerly these were composed of flowers of which we could only say that we hoped some of them might turn out well. They were nearly all foreign-raised flowers, and as they were cut from under glass they were certainly in most instances flimsy and poor in colour. Now, however, since so many Roses have been raised in our own country, the case is completely altered, and it is certainly very remarkable that in the first-prize stand with which Messrs. A. Dickson & Sons were the winners all the flowers were of their own raising. They comprised Countess of Caledon, Tom Wood, Lady Clanmorris, Ulster, Killarney, Eileen, Mrs. W. J. Grant, Mrs. Mawley, Bessie Brown, First Cross, Mrs. Grahame, and Daisy; they also secured the first prize for the best twelve blooms of any new Rose with a splendid dozen of Mrs. W. J. Grant. In the amateurs' division the Rev. J. H. Pemberton was first with six new Roses—viz., Marquise Litta, Marchioness of Downshire, Captain Hayward, Helen Keller, Charlotte Guillemot, and Mrs. S. Crawford, and of these only two were from foreign raisers.—D., *Deal*.

NAPHTHALENE.

I HAVE read with some surprise, and not a little enjoyment, an article entitled "Naphthalene" in your issue of last week (page 47), and as its contents concern me personally in the dual capacity of chemist and inventor of the paraffin-naphthalene emulsion I feel called upon to set your readers right on certain points.

It would be well for the public to clearly understand that the formulæ and prescriptions put forward by your contributor Mr. Abbey are imperfect quotations from, and covered by, the complete specifications of my English patent (13201, 1895) or its German counterpart (88,566), that both these patents are the trade property of firms who might sue for damages any persons who infringed the patent rights by following Mr. Abbey's instructions.

It should also be understood that even preparing a patented article for home or personal use is legally an infringement of patent. This is a matter with which I have no personal concern, but I am concerned in the obvious failure that would follow the attempts of any gardener to make an effective wash from Mr. Abbey's directions, as he has strangely muddled and misinterpreted the instructions.

All residents in Kent and Surrey have been secured free rights under this patent, and any such persons with sufficient interest in the garden to seek a cure for its pests can obtain adequate instructions by applying to the South-Eastern Agricultural College, Wye, Kent.

Mr. Abbey's article, "Naphthalene," certainly holds pride of place in my album of curiosities of chemical literature. I picture the writer as a gentleman brimful of chemical zeal and horticultural acumen, and with the trifling assistance of his native genius and a chemical text-book a little out of date, he has certainly produced an essay of an extraordinary and astounding kind.

Some little experience in reading the papers of students of chemistry has brought occasional relief to the tedium of the task, but in all my life these eyes have never yet found refreshment on such a glorious and unstinted flow of chemical "bowlers" of the very finest type—no mere batch of unnamed seedlings, but stage flowers of the choicest named varieties.

Perchance your interesting contributor is merely joking, some hearty horticultural humourist who is having his little fling at the expense of the unfortunate complexities of organic chemistry. If so, I cry, "Hold, enough, have mercy, and vent your merry wit on some less serious science—entomology, nematodes, anything long-suffering, more fit for such attentions."

Meanwhile I would respectfully urge that Mr. Abbey be completely insulated in your readers' minds within his own charmed circle of chemical curiosities, where the naphthalene potassium ($C_{10}H_8K_2$)! raises no smile, where the fertilising assistance of nitrobenzene raises no blush to Flora's cheek, and the softsoap prepared from paraffin and potash proves perfect quietus for impetuous eelworm or lurking bacillus

Finally I would heartily congratulate so bold an investigator on his safe survival of such perilous laboratory exploits as are set forth in his paper on "Naphthalene," and that he still lives to enlighten, stimulate, and amuse is scarcely less astonishing than his literary production. I enclose my card.—THE PATENTEE.

[If patents were granted for good humour and happy, racy expression under trying circumstances such as alleged "infringements" and "misquotations," we think our distinguished correspondent would be entitled to the grant. His preparation we have heard spoken of in the highest terms of approval by a gardener whose facilities for testing various compounds for the destruction of plant pests are such as are possessed by few persons who are scientifically or practically interested in the important subject.]

Notes & Gleanings

EVENTS OF THE WEEK.—Besides the Rose shows, as on page 73, the Committees of the Royal Horticultural Society will meet on Tuesday at the Drill Hall. On Wednesday Chester is to be *en fête*, while the Woking Society holds its show on the same day.

—— WEATHER IN LONDON.—Until Monday night, when a heavy thunderstorm passed over London, no rain had fallen, and town gardens were very dry owing to both the sun and the winds. There was a shower on Monday afternoon, but the storm did not commence until about seven o'clock. The lightning was very vivid, and the thunder loud, the rain descending in torrents for some time. The air was fresher on Tuesday morning, and it was slightly cooler. Another storm with rain came in the afternoon of that day. Wednesday was very threatening.

—— MONARCH STRAWBERRY.—I think Laxton Bros. deserve to be congratulated for giving us a good Strawberry that will travel well. I planted a few runners last October, and they have exceeded my expectation. The plants are most robust, and produced an enormous crop for the first year, some scaling 2 ozs. I planted them by the side of Noble and Royal Sovereign, and gathered fruits off all three varieties on the same day. I predict a great future for this Strawberry in the south of England, as it will travel to Glasgow as well as the Royal Sovereign will travel to London. In fact there is very little difference in the fruit when it is two days old, which is an invaluable desideratum.—KENT.

—— THE CHESTER SHOW.—We may remind our readers that what is expected to be a great horticultural exhibition will open at Chester on Wednesday next, the 28th inst., continuing over the following day. The show of last year, as will be remembered by experienced visitors, was too large for the tents which were provided. This year, no doubt, better provision will be made in that respect, and as we are informed competitors are anticipated from various parts of the kingdom, a great and diversified display of garden products will be arranged on the famous Roodee of the historic city. A gala consisting of various attractions is also to be held, and with fine weather a great success in every way is confidently anticipated. The railway companies are offering special facilities in connection with the show, and horticultural vistors will not forget to call at the great nurseries of Dicksons, Ltd., which are only a very short distance from the station. Major Walker-Jones, Grosvenor Chambers, 6, Newgate Street, Chester, is the secretary of the exhibition.

—— CURRAGHMORE AND PENRHYN CASTLE.—I visited both of those beautiful Irish and Welsh gardens within the last few weeks, and shall state immediately why I mention both names together. I presume it is unnecessary to say anything of the wild picturesque grandeur of North Wales and its host of famous sights all within easy reach of Bangor, where I formed one of a small party for some days, seeing the famous castles of Carnarvon, Conway and Beaumaris, the Menai Bridges, Rhyll, Llandudno, Holywell, the various quarries, passes through the mountains, and delightful valleys, and, not least, a visit to Lord Penrhyn's castle and gardens. Enjoying some well-earned holidays, I took no notes, and will not go over the customary ground of describing, even from memory, fruit gardens and fruit houses, well kept, well stocked, and intelligently conducted; flower and terrace gardens, with greenhouses and conservatories, where some rare and new beauty meets the eye, peeping out here and there; nor even the tempting landscape as seen from the castle keep, where an American visitor exclaimed a short time previously to Mr. Speed, the head gardener, "Well, if there is a finer prospect in this wide world, I have no wish to see it." He had been after seeing a large portion of it. I have been about pretty much myself, and have inflicted many columns of what I have seen on readers of the *Journal of Horticulture* for twenty years, and I am inclined to agree with our American cousin. However, description is not my present object, but to refer to a curious coincidence. The worthy veteran above referred to, Mr. Speed, practically commenced his respected career near here, at Curraghmore, the well-known residence of the Marquis of Waterford, some thirty-four years ago, as head gardener. I spent yesterday there and in Portlaw adjoining, where a few of the old veterans who remember him still survive.—W. J. MURPHY, *Clonmel*.

—— GARDENING APPOINTMENT.—Mr. George Arthur has been appointed head gardener to E. D. Stern, Esq., Fan Court, Chertsey, Surrey.

—— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The Merchant Taylors' Company and the Skinners' Company have each given a donation of £10 10s. to the funds of this Institution.

—— ROYAL HORTICULTURAL SOCIETY.—The next meeting takes place on Tuesday, July 27th, in the Drill Hall, Victoria Street, at twelve. A silver Flora medal is offered for competition (amateurs) for best collection of Cactaceous plants. At 3 P.M. Mr. W. D. Druery will give a paper on "Familiar Garden Insects, Friends and Foes."

—— DR. JAMES CLARK, who has been so successfully engaged for the past six years in University Extension work in agriculture and horticulture, was in March last offered and accepted the Professorship of Agriculture in the Yorkshire College, and the Directorship of the Agricultural Department. It is the intention of Professor Clark to introduce regular horticulture into the College curriculum, and a prospectus of a short preliminary course on fruit culture has just been completed.

—— THE SOUTHAMPTON HORTICULTURAL SOCIETY.—It is satisfactory to be able to report that at the recent meeting of the Town Council the proposal to rescind the sanction given to the Horticultural Society to hold its annual summer Show in an enclosure on the Common of the town was withdrawn, and the Show will therefore be held as usual on the 31st and August 2nd. Some very foolish observations as to the right of the townspeople to clamour for free admission to the show grounds, and even to pull down the fence if not admitted; were very properly severely rebuked, as tending to incite breaches of the peace; whilst it is evident that no similar enclosure on the Common can ever again be permitted, it is hoped that the Horticultural Society may not only this year hold its Show in peace, but also have, what is so much needed, a very successful one.—A. D.

—— ISLE OF WIGHT.—The members of the Isle of Wight Horticultural Improvement Association, by the kind permission of Sir Charles Seely, Bart. (President), visited, on Wednesday, July 14th, Brooke House and gardens. The day was gloriously fine, and over fifty members availed themselves of the privilege to inspect the Island home of this gentleman, whose name and generosity extend far and wide. The party was met by Sir Charles and his daughter and son-in-law (Colonel and Mrs. Leech) at the front of the mansion. After preliminary introductions the President led the party round the park, which is beautifully undulating, and contains a mixture of many rare trees and shrubs, which are relieved by miniature lakes and cascades. The roseries and flower beds on the terraces were next visited; from the terraces there is a charming landscape view with the sea in the distance. A huge Oak, planted by Garibaldi in 1864, was next inspected. A tour of the extensive houses was much appreciated; the 3000 feet of Peach houses, with healthy trees bearing heavy crops of large and highly coloured fruits, received favourable comment, as did a large and miscellaneous stock of Orchids and stove and greenhouse plants, which receive excellent culture at the hands of Mr. W. Tribbick, F.R.H.S., who is a thorough all-round gardener. The vineries, in which are strong, healthy canes, carrying fine crops of fruit, particularly a lean-to house of Muscat of Alexandria, with large bunches of good shape and highly coloured berries. Before the inspection of the kitchen garden and fruit orchard tea was partaken of in the dining-room, where ample justice was done to the good things provided by the President. After tea the many valuable pictures which adorn the interior of Brooke House were seen and much admired. Then the party was photographed on the lawn, after which votes of thanks and cheers were given for Sir Charles Seely and Colonel and Mrs. Leech for their kind hospitality. Sir Charles, in acknowledging the votes of thanks, expressed a hope that he might at an early date have another visit from the members of the Association. The members afterwards broke up into small parties, some going to the kitchen garden, whilst others visited Brooke Church and mounted Brooke Hill, which is several hundred feet above sea level, and from which there is a commanding view of the southern and western parts of the Island. Many strayed to the shore, and were rewarded not only by the pleasures of a bathe, but by a view of the lifeboat. The day was thoroughly enjoyed, and the members returned to their homes in all parts of the Garden Isle feeling highly compensated for any little sacrifices they had had to make so as to visit the marine residence of their worthy President. The day can undoubtedly be counted a red-letter one in the history of the Association.—S. H.

—— PLANT COLLECTING IN ASIA.—Professor N. E. Hansen, Horticulturist of the United States Experiment Station of South Dakota, at Brookings, was recently appointed a special agent by the Secretary of Agriculture to visit Eastern Russia, Siberia, and the elevated plateaux of central Asia, to gather garden, farm, fruit, shrub and tree seeds. Professor Hansen states that the few plants from this dry inland European region already tested in South Dakota, Manitoba and the north-west territory have proved hardy, and it is his intention to collect during the present summer and autumn as complete a representation of the plants of that region as possible.

—— DIPLADENIA BOLIVIENSIS.—This pretty stove plant is perhaps, the most beautiful, and certainly the most easily grown Dipladenia in cultivation. As it is of free growth, and most floriferous in character and blooms when in quite a small state, it differs from the other members of the genus both as regards the habit of the plant and in the colour of its flowers, which are pure white with an orange coloured throat. These are most useful for cutting purposes, lasting a long time in water or when wired for wreath or bouquet making, provided a small piece of damp moss be wired on to the base of the tube. The Dipladenias succeed best in pots, and require a moist atmosphere during the season of growth with abundance of heat. For training along the roof of the stove it is unsurpassed.—H. T. M., *Stoneleigh.*

—— SHIRLEY GARDENERS' ASSOCIATION.—The monthly meeting took place on the 19th inst. at the Parish Room, Shirley, Southampton, Mr. B. Ladhams, F.R.H.S, presiding over a good attendance of the members. The subject of the evening was a Rose show and discussion on the exhibits; but owing to the exceptionally hot, dry period Roses in the district are practically over, hence a small display was the result. There were three prizes offered for twelve Roses, Rev. W. J. Rudge being first, and also securing certificate for best Rose in the show; Mr. W. F. G. Spranger (gardener, Mr. H. Curtis) being awarded second. There were good collections, not for competition, shown by Mr. W. H. Rogers, Red Lodge Nursery, and Mr. B Ladhams, Shirley Nurseries, and a collection of buttonhole Teas by Mr. T. M. Lord (gardener, Mr. W. Knapp). Mr. J. Key Allen, F.R.H.S., showed fruit, Mr. Curtis Tomatoes, Mr. Jeffrey Sweet Peas, and Mr. Ladhams a fine collection of hardy and herbaceous plants. The discussion was joined in by a number of the members, and was of an interesting and useful character. Votes of thanks to the exhibitors and Chairman closed the meeting.

—— WAKEFIELD PAXTON SOCIETY.—The annual exhibition of Pelargoniums was held on Saturday, 10th inst., when over seventy trusses of bloom were shown in glass bottles. It was declared to be a grand show, and the best yet seen there. There was an average attendance of members. Lieut. Goodyear was in the chair, and Mr. W. Hudson, Sandal Grange, in the vice-chair. Mr. W. E. Corden, Wakefield, who has often read papers on these occasions, contributed a short essay on the cultivation of the plant from seeds, in which he has been a distinguished specialist. He advocated a firm yellow loam, mixed with well-decayed cow manure, and that the effort should be made to have a bushy plant, and not one running up like a Hop. Watering regularly prevented the loss of rootlets, and the pots should be clean. He declared that two of the specimens shown of white double blooms, grown from his seed by two members, were as fine as any in England. Mr. Milnes proposed a vote of thanks to the essayist in some lengthened remarks, with thanks also to the exhibitors, who included Messrs. Corden, Moody, Hudson, Vere, Calvert, and Thomas.

—— PLAGIANTHUS LYALLI.—Until recent years this New Zealand Malvaceous shrub was treated solely as a greenhouse plant, and even now very few gardens can boast a really good specimen outside. In the south-western counties it is perfectly hardy, and attains a considerable size if planted in a sheltered corner where it will not get cutting north or east winds. About London and further north it is better to give it the protection of a wall, as the wood then becomes better ripened for the winter. The flowers are produced during June and July from several of the lower nodes of the current season's growth. They are pure white, about 1½ inch across, and produced three or four together from each node. The leaves are from 3 to 4 inches long, more or less ovate, inclined to cordate, with acuminate apex and deeply cut margins. Growths 2 to 3 feet long are often made during summer. These should be shortened to half that length the following spring before growth commences. A light loamy soil is suitable for this plant. Cuttings of half-ripened wood can be rooted if put into sandy soil in a close case during July. Young plants should be sheltered in a cold frame during their first winter.—D.

—— THE GARDEN ISLE.—Mr. C. Orchard writes:—"We are having glorious summer weather now, and it is checking the ravages of the Potato disease that set in so early throughout the Island. Apples in some places are plentiful, in others very scarce, and this occurs in places close to each other. It very much depended on the condition and position of the trees during the cold easterly winds that prevailed at the time they were in bloom. Strawberries have been plentiful, Plums and Pears scarce. The hay harvest is the best for years."

—— MELONS.—Although it is admitted that in granting awards to Melons it is ordinarily done in the dark as to the general merits of the variety honoured, one thing is very certain—that is, that a really good Melon is a very highly appreciated fruit. That fact, doubtless, has much to do with the practice of making awards to single fruits of seedling varieties. Whenever it is the good fortune of the Fruit Committee to have before that body a Melon that deserves an award of merit, nothing is more remarkable than is its quick vanishing properties. Doubtless it is due to its inherent goodness, and of the general desire shown to taste the *rara avis*. It is rather awkward for the reporters, no doubt, who in seeking for the subject of the award, find only a plate and a card. However, it doubtless gratifies the exhibitor to thus note the tribute paid to the excellence of his "fruit."—A. D.

—— JUBILEE DAY IN RHODESIA.—Jubilee Day in Rhodesia was observed as a great tree-planting day in honour of the Queen; but it is said the distinctive feature of the celebration was that each white man who planted a tree had himself to dig the hole for it 3 feet in diameter, and 3 feet deep. The planter was allowed to obtain the help of a friend in this task, but the essence of the celebration was that the hole should be made by the white planter himself. He was not allowed to hire a native to do the work for him. This labour was regarded as "a voluntary act of individual homage to the Queen." The Administrator, Lord Grey, himself set the example, and the natives on Jubilee Day saw a strange sight—white men voluntarily doing what they contemptuously call "Kaffir work" in honour of the Great White Queen over the water. Let us hope it would do them good.

—— USES OF THE POPPY.—The Poppy is cultivated for the sake of the opium which it yields. This is one of the most valuable of medicines, says an Irish contemporary, and one which, as a commercial article, exceeds in importance every other drug in use. Opium is the dried juice of the unripe capsules of the white Poppy. The Poppy is also of great value for its oil and other purposes. The seeds, which contain no opium or other narcotic principle, yield about 40 per cent. of oil, and the oilcake, which is much appreciated by the natives of India, is useful for manure and cattle feeding. These seeds were well known to the ancients as a pleasant article of food, and some German cakes have Poppy seeds plentifully sprinkled on the top. The oil expressed from them is perfectly wholesome, and it is supposed that one-half of the oil used for cooking and otherwise for alimentary purposes in France is of this kind. It is a valuable and much used medium for artistic oil painting. The inferior qualities are consumed in soap and varnish making, and for burning in lamps. The oil is also very extensively used in the valley of the Ganges and other opium regions for food and domestic purposes.

—— HOW FROST AFFECTS VEGETATION.—In his most exhaustive and instructive work, "The Student's Text-book of Botany," Professor Vines gives an interesting explanation of the manner in which extreme cold injuriously affects vegetation. Injury or death by exposure to cold is only induced, he says, when the temperature falls below the freezing point. The liability to injury from frost largely depends upon the amount of water contained in the plant. Dry seeds and the winter buds of trees can readily withstand very low temperatures, but when they contain much water—as when the seeds are germinating or the buds unfolding—they become very susceptible to injury from this cause. When any part of a plant which contains a large proportion of water is exposed to a low temperature a portion of the water contained in the cells escapes from them and gets frozen on their surface, the whole tissue at the time contracting; the water does not freeze in the interior of the cells. The water which has thus escaped and become frozen forms an incrustation; but it has been found that this formation of ice is not necessarily fatal in all cases. If the frozen part be slowly thawed the cells may gradually reabsorb the water, and so return to their previous normal condition. If, however, the frozen part is rapidly thawed the cells cannot absorb the water with sufficient rapidity, and it therefore either collects in the intercellular spaces, causing discolouration and decay, or runs off and evaporates, so that the part dries up.

Sheffield Chrysanthemum Society.

The usual monthly meeting was held on the 14th inst. in the Society's rooms. Mr. J. Haigh was elected to the chair, when a paper was read by Mr. Thos. Gartery of Rotherham, on the Tomato. It was a very interesting and instructive one, commencing with a few general remarks having reference to its names, date of introduction, medicinal qualities, methods of cooking, its uses for decorative purposes. He then fully explained his method of cultivation, beginning with the sowing of the seed, treatment of young plants, methods of planting in pots and boxes, watering, feeding, and concluding with the general management of mature fruit-bearing plants. Messrs. Marshall, Scott, Slaney, Winter, Hannah, and Morton, professional growers, either joined in the discussion that followed, or added to the information previously given.

The professional members competed for prizes with pot plants in bloom, amongst which were some good Gloxinias; the awards being to Messrs. C. Scott, T. Morton, and S. Lomas for first, second, and third prizes respectively. The amateur section exhibited cut blooms which contained Stephanotis, Cannas, Liliums, Gloxinias, and Roses. Messrs. P. Cox, W. Willgoose, and Mr. W. H. Willford were successful in the order in which their names are given. A vote of thanks to Mr. T. Gartery for his excellent paper, and one to the Chairman, concluded the meeting.

Chrysanthemums in April.

Chrysanthemum shows of 1897 in Australia have just passed (May), and as I have had an opportunity of visiting many of the leading competitions in this Colony, a few notes may be interesting.

The Best Twelve Japanese Blooms.—These were selected at ten shows, where there was good competition, with the result that 120 blooms were taken from thirty-seven varieties, ten of which were raised in Victoria, and in a few instances the first time exhibited.

The following are placed as nearly as possible in "the order of merit:"—Madame Carnot, Viviand Morel, Chas. Davis, Robt. Owen, Mons. Panckoucke, Mdlle. Thérèse Rey, Niveus, Good Gracious, Golden Gate, H. L. Sunderbruck, Mrs. H. B. Higgins, Etoile de Lyon, The Convention, The Wonderful, Euterpe, Mrs. G. Gunn, William Seward, Philadelphia, Rose Wynne, L. Cartelidge, E. Molyneux, Col. Smith, Silver King, Viscountess Hambledon, Duchess of York, Miss Nellie Pockett, Buff Globe, Pallanza, Abbé Mendenhall, Mutual Friend, Glen Eira, John Pockett, Lord Brassey, Eva Knowles, R. C. Kingston, Nyanza, and Amiral Avellan (of course the newer varieties are to a disadvantage on account of their not being grown by most of the exhibitors).

The neighbourhood of Malvern (Australia) has not been so favourable this season for developing colours, the wood not being so well matured as usual, probably owing to more than the average amount of rain falling when the plants were making the last growth previous to forming buds.

Saving Seed.—To those contemplating saving seed it may not be generally known that by saving from one plant (provided it has been fertilised with other varieties) nearly all the colours can be obtained that are known in Chrysanthemums, although one colour will generally predominate. The variety for bearing seed should always be carefully selected, as some varieties have a tendency to give the greatest rubbish imaginable, while others produce a good average of promising sorts. The worst of all that I know for seeding are the hirsute varieties. I have never, with one exception, obtained anything meritorious out of the hundreds of seedlings raised from that type, although one really good was raised here, and is known by the name of Australian Belle. I understand it will be sent out this season.

A correspondent of the *Journal of Horticulture* some time back wished to know of any sports that originated during the last year or two. Sports here this season have not been very numerous. There have been several of the Queen family, but none, so far as I know, of special merit.

Pride of Madford Sport.—I mentioned this last year, and I am able to say it is now fixed. The colour is chestnut crimson, reverse of petals lined and tipped with gold. It is named Pride of Stokell, as it originated in the gardens of Mr. S. Armstrong, Stokell, Malvern, Mr. F. Upton being the gardener.

I am sending photographs. The small one represents a bed of Chrysanthemums. The plants are about 1 foot 9 inches apart in the rows, and the rows about 2 feet 6 inches asunder. Each plant has about seven or eight shoots supported to one stake, which is completely hidden with the foliage. They are disbudded until the florets show colour, and then any lateral shoots that may start are allowed to remain for later flowers, which, although much smaller, produce a very good effect.

The larger photo shows plants grown in a more natural way; they are about 3 feet apart, one stake being used for each plant, and four to eight shoots tied to each stake. They are then allowed to make the flowering break without tying. The colours of the blooms are really good, and by not forcing them to the same extent as the others the flowers last much longer.—Thos. W. Pockett, *Curator, Public Gardens, Malvern, Australia.*

[We are very much obliged to our correspondent for his interesting communication, and for the April scene represented in fig. 12.]

HAREWOOD HOUSE.

Situated in one of the most picturesque dales in Yorkshire, eight miles from Leeds, on a commanding eminence, stands Harewood House, the seat of the Earl of Harewood. The park is 1800 acres in extent, and within stands the dismantled Castle of Harewood, built in the reign of Edward I. by the De Lisles. It is said to have suffered considerably during the civil wars. But Sir John Cutler, who held the lands of Harewood, and lived at Gawthorpe Hall, used a considerable quantity of the stone for the building and repairing of farmhouses. The palatial Harewood House was begun in 1759 by the first Lord Harewood and completed in 1771, when the old Gawthorpe Hall, which stood close to the site of the modern mansion, was pulled down. This was for several centuries the seat of the knightly families of Gascoigne, Redmayne, and Cutler, whose tombs are now within the ancient church of Harewood, standing at a short distance from the house. Within this church is the tomb of the celebrated Lord Chief Justice Gascoigne and his lady; he it was who, fearless in the discharge of his duties, committed the Prince of Wales, afterwards Henry V., to prison for contempt of court.

The park is entered from the village by a superb arched gateway with two dwellings. It is in the Doric order, and has eight columns 20 feet high, 17 feet of which is solid stone. It is supposed to be one of the most imposing entrance gates in the kingdom; the first stone was laid in 1801.

The house is a fine specimen of Corinthian architecture. The length, with wings, is 249 feet, the width 85 feet, and the height 62 feet. In the centre is a handsome pediment supported by six three-quarter Corinthian columns 35 feet high. The family of Lascelles, according to Burke, are descended from John de Lascelles of Hinderskelfe (now Castle Howard), living in 1315 A.D. The estates of Harewood, which are about 30,000 acres in Yorkshire, were acquired by purchase early in the eighteenth century by Henry Lascelles, Esq., whose son was created Baron Harewood of Harewood Castle.

The terrace at Harewood is about 350 feet in length. There are five fountains, two of which are in a line with the house, the others being on the second terrace, by which we descend by stone steps. It is laid out with geometrical beds, and is bounded from the park by a high balustraded wall. Within the pleasure ground is a lake of 60 acres fed by a grand cascade falling about 30 feet. The margin of the lake is fringed by Water Lilies and Nelumbiums, and running around the outside walls of the kitchen gardens facing the lake is a wide herbaceous border three-quarters of a mile in length, filled with a choice selection of all that is useful, beautiful, and interesting.

The kitchen gardens are 7 acres in extent. Many of the wall trees are young, having taken the place of worn-out specimens, for Mr. Jeffrey, the head gardener, has, during the five years he has been here, gradually renovated the fruit department. A north wall is covered entirely with Morello Cherries, and in one corner, between the south and east walls, is an ancient Mulberry planted in 1769. A wall with an eastern aspect, formerly occupied by Plums, is now being covered with Sweet Cherries, which are doing well. Another wall with a southern aspect, used as a Peach wall, is now being covered with thriving young trees of dessert Pears and Apricots. The vegetable quarters bespeak at once the impress of a master hand, and the supply of a nobleman's household in the abundance, quality, and perfect cleanliness of the whole.

The glass houses are fifteen in number, in two continuous ranges facing south, with a frame ground between. The first house to enter is a large vinery, 60 feet long by 25 feet in breadth, length of rafter 36 feet. Here is the famous Canon Hall Muscat Vine. It is planted in the outside border, and covers the entire roof of the house, and is bearing at present 120 bunches averaging 2 lbs. each, over 500 bunches having been removed. The whole of the wood is not more than four years old, the old rods running vertically from horizontal limbs on each side of the main stem. The next vinery is of the same dimensions as the first, and contained a grand crop, both in size of bunch and berry and colour, of Black Hamburgh. Two Vines of Muscat Hamburgh, perfect in finish, are in this house. Thin-skinned Grapes are only used at Harewood. The next vinery was also of Black Hamburgh.

In this range is also a Cucumber house, in which on iron supports had been trained Sutton's Climbing French Bean. Mr. Jeffrey speaks highly of it for forcing and flavour. A house containing Tomatoes in pots, which had good crops, some fruit ripe, the varieties being Perfection and Ham Green Favourite. There are also two Fig houses containing such varieties as White Ischia, Brown Turkey, and White Marseilles.

The other range of houses are principally devoted to plants, but in this range is also a vinery, mostly of Black Alicante with a rod or two of Lady Downe's, but this latter is not at all popular. Another house was planted with Tomatoes, and one had a crop of Melons, but these are not in much request at Harewood. Several of the plant houses here are to have new roofs; one is to be made into a loftier structure, and

is at present planted with Roses, Fuchsias, and many old-fashioned plants, such as Clianthus puniceus, Lasiandra macrantha, Chorozema cordata, Acacias, Myrtles, Scented Pelargoniums of sorts, the old P. tomentosum being amongst them. The stove is 80 feet long, and it is intended to re-roof this house. Mr. Jeffrey is a great advocate of the planting-out system, and in front of this stove in a walled-in bed having bottom heat below were growing Passiflora edulis bearing almost 100 fruits the size of a hen's egg. The same house contains Passiflora laurifolia full of bloom with some fruit swelling; it promises to be equal in every respect to its neighbour. Mr. Jeffrey considers the fruit quite equal in flavour to edulis. A really fine plant of Aristolochia

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE, JULY 13TH.—Present: Dr. M. T. Masters (in the chair); Mr. Veitch, Dr. Bonavia, Rev. W. Wilks, Prof. A. H. Church, and Rev. G. Henslow, Hon. Sec.

Malformed Fungi in Mushroom Bed.—A letter was received from Mr. Taylor, Penbridu, Mold, criticising the reports sent to the last meeting with reference to the loam, as he had splendid results last year with the same loam cut from the open pasture. As the specimens have been lost in the transit to Kew the Committee has been unable to receive the report of an expert upon the fungi themselves.

FIG. 12.—CHRYSANTHEMUMS IN APRIL.

elegans bearing hundreds of curious and beautiful blooms arrested attention, as did Ipomæa Horsefieldi and Stephanotis.

An exotic fernery contained fine plants of Adiantum farleyense and Cheilanthes elegans, and interspersed were a number of Rex Begonias. Amherstia nobilis is represented by three specimens brought from Trinidad, and recently planted here.

Another house contained Orchids, and then came two houses with greenhouse plants, in which were double Primulas, which are grown by the hundred; and here I observed at least a hundred pots, containing each three and four bulbs as large as a Spanish Onion of Amaryllis Johnsoni. The pots were mostly 7-inch in diameter, and the sight of the plants in flower must be very fine. Several hundreds of bush Chrysanthemums are grown, and I noticed a fine lot of Lilium Harrisi just flowering. In the large vinery at one end are planted two groups of Hedychiums coronarium and Gardnerianum remarkably strong, promising well for bloom. In one of the stoves were about half a dozen large Hibiscus in sorts. Mr. Jeffrey can use these for dinner-table glasses nine months out of the twelve. They are short-lived, but brilliant.—F. STREET.

Cucumber with Adherent Leaf.—A specimen was received from Mr. E. Horsley, gardener to Rev. W. Wilks. The petiole of a leaf had become fused with the base of the fruit, the result being a distortion in the latter—a not uncommon procedure.

Cattleyas, synanthic.—This was a fusion between two flowers, the effect being to arrest some parts of the whorls, so that each flower became dimerous. There were two lips.

Poppy with Pistilloid Stamens.—A flower of Papaver Rhæas was exhibited with this peculiarity. It is rare in this species, but not infrequently in some others, as the Icelandic.

Chemical Composition of Cattleya.—Two papers prepared by Mr. Smee were laid before the Committee by Mr. Veitch, to whom they had been addressed, as Chairman of the Orchid Committee. The first contained some figures connected with the composition of the atmosphere; analyses of old and young pseudo-bulbs were also given, and of the flower, including observations upon the colouring matters of plants. Prof. A. Church, having given careful consideration to the first of the two papers, reserving the second for a future meeting, remarked that Mr. Smee had scarcely paid sufficient attention to the more recent

analyses of the atmosphere and of rain ; the amount of CO_2 in the free air over land and sea being now found to be almost absolutely uniform everywhere (except where locally contaminated), and less in quantity than 3 parts in 10,000, so that no conclusions could be drawn from the data furnished in the paper on this point. With regard to the amount of ammonia in the air, it is so infinitessimally small in quantity, that it can only be estimated by the most modern and refined chemical operations, so that he was obliged to express some hesitation in accepting Mr. Smee's statements on this point. With regard to Mr. Smee's analyses of pseudo-bulbs and of flowers, Prof. Church observed that they agreed fairly well with average results hitherto obtained from terrestrial and epiphytic plants, but he thought that the percentage of undetermined ash constituents—viz., about one-half, was far too great, and he questioned the presence of aluminium, observing that though terrestrial species of Lycopodium contain much of this metal, epiphytal species of the same genus contain none. He felt sure that some ingredient was wanting which had not been determined. With regard to floral colouring matters, Mr. Smee did not appear to have consulted recent researches. Prof. Church had proved that a number of reds, blues, and purples, though called by different names—*e.g.*, colein in the Coleus, erythrophyll in Copper Beech, fruits, &c ; œnolin in black Grapes and anthocyan were absolutely the same thing, being represented by the formula, $C_{20}H_{20}O_{10}$. These became purplish in neutral cells, blue in alkaline, and red in acid cells. Even the blue-green of a certain Ixia was due to an alkaline solution of the same substance. With regard to the Beetroot, however, and plants allied to it, as the Amaranthus and Buckwheat, he found that the red-purple was of a different nature, and he had called it "amaranthin." It gave neither a scarlet nor blue reaction, neither green nor yellow with acids, but Prof. Church had as yet not determined its actual chemical composition, although he had found it to differ from anthocyanin by its insolubility in absolute alcohol, and by the absence from its spectrum of definite absorption bands. With regard to nutritive solutions, Prof. Church thought that the ordinary solutions for plant culture containing phosphates and salts of lime should be used for Orchids, not the solution surcharged with nitrogen compounds recommended by Mr. Smee. He would suggest spraying with "pulverised" solutions the epiphytic Orchids, for he had proved with Echeverias—as Boussingault had also long ago with other plants—that salts if moist could be absorbed by the surface of the leaf, so that when a lithium salt was placed upon a lower leaf it was detected in others above. Dr. McNab had previously proved the transmission of lithium salts imbibed by the roots throughout the plant, following the suggestion of Prof. Church to use this salt. Mr. Veitch and Dr. Masters called attention to the practice carried out by amateur Orchid growers of suspending a bag of carbonate of ammonia (smelling salts), so that the vapour might be absorbed. Mr. Henslow suggested that it might be absorbed with the aid of vapour of water, as he had found by experiments that this can be absorbed by leaves.—(*Transpiration in a Saturated Atmosphere*, Journ. Lin. Soc, Bot., xxiii., page 303).

CARNATIONS AT CHELSEA.

EVERY year now for several seasons there has been a rich display of Carnations in the Royal Exotic Nursery, Chelsea, and this year proves itself to be no exception to what has come to be regarded as a rule by horticulturists. As with other plants grown by Messrs. J. Veitch and Sons, Ltd., Carnations are done thoroughly well, and the arrangement of varieties in beds permits of their being readily inspected by the several visitors. The different shades of colour are of course very numerous, and the flowers are, as a rule, of high quality, though perhaps not quite so large as those that are cultivated in the purer atmosphere of the country.

There can, after seeing the Chelsea collection, be no question as to the adaptability of Carnations and Picotees for culture in towns. Here they make capital "grass," and produce large numbers of blooms over a considerable period of time. If these results can be achieved without any elaborate preparation of the soil in the beds, it may be safely said that better flowers and plants might be had by those persons who have abundance of time to devote to the plants. Not only are they good for large gardens, but also for small ones; indeed in the most enclosed suburban garden they may be grown to a state well approaching to perfection. Some varieties may thrive better than others, but it is not difficult for anyone desirous of doing so making a judicious selection under the advice of some experienced grower, such as Mr. Weeks at Chelsea.

In drawing attention to this collection it may be permissible for the writer to call particular notice to one or two which were apparently of more than ordinary merit. These, however, are somewhat numerous, so that those named must not be taken as the whole of the varieties in the selection, but simply as a representative selection from them. They have been chosen, not especially with regard to the quality of the flowers, but also with respect to their habit of growth, which is of almost equal importance to the amateur grower, though not so much so to the one who grows especially for exhibition. In this case, of course, the quality of the flowers is of paramount importance, as it is immaterial to him how many blooms he gets from any individual plant provided they are perfect, or nearly so.

It is noticeable that many of the best of the varieties have had their origin in the splendid collection of Martin R. Smith, Esq., at Hayes. Referring first of all to the selfs, we might call attention to Exile, a soft rose-hued flower of exquisite beauty. Her Grace, a delicate blush, is of fine form, as also is Nabob, an orange buff, which is very distinct. The bright scarlet of Paradox is very striking, as is the blush-tinted bloom of Seagull. Cantab and Joe Willett are older than those that have been mentioned, but it will be a considerable time before they are ousted from popular favour, and the same may be said of Rose Celestial and Winter Cheer. Of yellows, Corunna and Germania are very beautiful, as are the pure white Snowdon and Mrs. Frank Watts. Such old Fancy varieties as The Dey, Duchess of Portland, and George Cruickshanks meet with favour from many people, as do the lovely light and heavy edged Picotees.

Many of the yellow-ground flowers are exceedingly beautiful, and ought to have a prominent position in every garden where flowers are desired. Amongst the very best of these now in bloom are Eldorado, Mr. Nigel, Voltaire, and Golden Gate. In addition to those named, if one wished to augment the list one might add Hayes Scarlet, Sadek, Miss Audrey Campbell, King Arthur, Bendigo, and Miss Ellen Terry, and with these this brief notice must be brought to a close. Readers should take the first available opportunity of making an inspection for themselves.—SCRUTATOR.

HORTICULTURAL SHOWS.

NEWCASTLE.—JULY 8TH, 9TH, AND 10TH.

THE show was one of the finest ever held by the Society, and there were several new and interesting features. Some of the competitions did not bring forward so many exhibitors as formerly, one reason, perhaps, being the knowledge that certain famed prizewinners would be there to maintain their glory and renown in the world of frnit and flowers, and another, that several other important flower shows were being held at the same time Still, the magnificent show in the enormous tent erected for this occasion was one to be remembered. Nurserymen and seedsmen were exceptionally well represented, and many lovely exhibits not for competition were shown by eminent florists. An enormous trophy of Palms, Coniferæ and hothouse plants, surmounted by the national flag, did credit to Mr. W. R. Armstrong. Messrs. Wm. Fell & Co. made a characteristic display of flower and foliage by ornamental grouping on each side of the entrance, for which collection they again secured the silver medal. The Jubilee was regarded by another exhibitor, who with scarlet "Geraniums," Cornflowers, and white Pinks, garlanded a mail cart in a most interesting and artistic fashion. The herbaceous plants were a fine feature of the Exhibition, but still the ordinary visitor looked most at the flowers and fruit.

First of all the Roses. In this summer show a Victorian prize was offered under the designation of "cut flowers," not only for the best collection of Roses, but arranged for effect. The first award was the gold medal of the Society, and the first prize collection was of great beauty. The prize, as did most of the leading honours for cut flowers, went to Messrs. Perkins & Sons, of Coventry. The exhibits by other famous Rose growers—Harkness & Sons, of Bedale, Mack & Son, Catterick—showed the present perfection of the national flower. Violas and Pansies from Mr. T. Battersby, of Hagg Hill, Blaydon, were very pleasing, the blooms being of excellent quality. The Carnations were choice in quality and arrangement, Messrs. Laing & Mather, Kelso, having as fine specimens as we have ever noted. The Begonias shown by Messrs. J. Laing & Sons, Forest Hill, were superb with their delicacy of texture and colour. Fruit from Sir Joseph Pease, Bart., M.P., at Guisborough, provided a feature that attracted much notice. A few of the prizewinners are named below.

For a group of miscellaneous plants, arranged to produce the most artistic effect, Mr. J. McIntyre was first, Mr. F. Edmondson second, and Mr. J. Cocken third. For six plants in bloom, distinct, Mr. F. Nicholas was the only competitor, and received the premier award. For six foliage plants, first, Mr. J. McIntyre ; second, Mr. F. Nicholas.

The Victorian prize for a collection of Roses arranged for effect went to Messrs. Perkins & Sons, Messrs. Harkness & Sons being second, and Mr. F. Edmondson third. For seventy-eight Roses, thirty-six varieties, first, Messrs. Harkness & Sons ; second, Messrs. R. Mack & Son ; third, Messrs. D. and W. Croll. Messrs. Harkness & Sons were the only exhibitors of forty-eight Roses, dissimilar, and received the first prize. Thirty-six Roses, dissimilar.—First, Messrs. Harkness & Sons ; third, Messrs. D. & W. Croll. Twenty-four dissimilar, trebles.—Messrs. Harkness and Sons again secured the premier award.

In the class for eighteen bunches hardy herbaceous and border flowers, dissimilar, Messrs. Cocker & Sons were first, Mr. F. Edmondson second, and Messrs. Harkness & Sons third. Twelve bunches hardy herbaceous and border flowers.—First, Mr. M. Campbell ; second, Messrs. Harkness & Sons ; third, Mr. F. Edmondson. For forty-eight Pansies, Fancy, distinct, Mr. M. Campbell was first, Mr. A. Lister second, and Mr. K. H. L. Bell third. For twenty-four Pansies, Fancy, distinct.—First, Mr. M. Campbell ; second, Mr. A. Lister ; third, Mr. W. Archer. Twenty-four Pansies, Show, distinct.—First, Mr. A. Lister ; second, Mr. W. Archer ; third, Mr. J. Wright. Twenty-four spray Violas, six blooms in each, not less than fifteen varieties.—Mr. M. Campbell first, Mr. T. Battensby second, and Mr. J. Cairns third. Twelve specimen glasses of Carnations, not more than six blooms in each.—First, Messrs. Laing and Mather ; second, Mr. M. Campbell ; third, Mr. J. Cairns.

In the fruit division the chief class was for a collection of eight dishes of fruit, distinct kinds (black and white Grapes allowed as separate dishes), and Mr. J. McIndoe was a fine first, followed by Messrs.

J. Tullett, J. Cocker, and G. Lonsdale. Collections of four dishes of fruit (Pines excluded), distinct kinds (black and white Grapes allowed as separate dishes), Mr. J. McIndoe, Mr. J. Cocker, and Mr. G. Lonsdale, as named. For four bunches Grapes, not less than two varieties.—First, Mr. J. Tullett; second, Mr. J. McIndoe; third, Mr. L. Thompson. Two bunches Grapes (White Muscat).—First, Mr. J. McIndoe. Two bunches Black Hamburgh Grapes.—First, Mr. L. Thompson; second, Mr. J. McIndoe; third, Mr. J. Lonsdale. Dish of Peaches.—First, Mr. G. Lonsdale; second, Mr. F. Nicholas; third, Mr. L. Thompson. Dish of Nectarines.—First, Mr. J. Tullett; second, Mr. J. McIndoe; third, Mr. F. Nicholas. Collection of six dishes of Strawberries (six named varieties).—First, Mr. W. G. Macfarlane. Dish of Strawberries.—First, Mr. W. G. Macfarlane; second, Mr. J. Macfarlane; third, Mr. F. Nicholas. For a collection of vegetables, five distinct, to include two of Messrs. Webb's varieties, which must have been grown from seed supplied direct from their establishment in 1896.—Mr. J. McIndoe was first.—("Newcastle Daily Leader.")

WOLVERHAMPTON.—JULY 12TH, 13TH, 14TH.

FAVOURED by three days of ideal "flower show" weather, this, the ninth, exhibition of the very enterprising and successful Society proved to be even more of a success than the fine show of last year. It was held, as usual, in the West Public Park, than which no more convenient and suitable position could well be found or desired, affording, as it also does, by virtue of its well-kept and attractive grounds, an additional pleasure to the visitors after inspecting the products in the five large marquees. Much credit is due to the Secretaries and their coadjutors for the excellent arrangements made for the staging of the vast array of exhibits favourable to the work of the competitors, judges, and reporters alike. Owing to indisposition Mr. W. A. Green, the Secretary, was unable to be at the show on either day, and, by request, Mr. A. Outram took over the management, and, it is needless to add, gave great satisfaction.

PLANTS AND FLOWERS.

In the open class for sixteen stove and greenhouse plants, Mr. J. Cypher, Cheltenham, secured the £20 first prize easily, with a very fresh and bright exhibit, consisting of well-bloomed specimens of Bougainvillea glabra Cypheri, B. Sanderiana, a grand Statice profusa, Erica Parmentieriana, and Stephanotis floribunda; also very good representatives of Erica ventricosa Bothwelliana, Ixora Williamsi, and a huge though somewhat sparsely flowered Phœnocoma, Anthurium Scherzerianum, and two excellent Crotons, Baron James Rothschild and Queen Victoria, supplemented by gigantic Palms, such as Latania borbonica, Kentias australis, Fortunei, and Belmoreana. For second honours, Mr. W. Vause, Leamington Spa, supplanted his rival, Mr. Finch, gardener to James Marriott, Esq., Coventry, with also a most creditable lot—the third prize being accorded to Mr. Finch.

For six plants in flower, Mr. Cypher again led off with excellent specimens of Ixora Williamsi, Bougainvillea Sanderiana, Ericas ventricosa, Bothwelliana, and Parmentieriana, a very good Clerodendron Balfouri, and an excellent Anthurium Scherzerianum, whilst Mr. Vause secured the second prize as the only other competitor with a good collection.

For six Palms, Mr. Cypher, Mr. Macdonald, gardener to S. H. Kenrick, Esq., Whetstone, Edgbaston; and Mr. Vause won in the order named with very fine specimens. In the class for six exotic Ferns, Mr. R. Sharpe, gardener to H. Lovatt, Esq., Lowhill, Bushbury, secured the first prize with excellent examples of Cyathea australis, Dicksonia antarctica, Gleichenia Mendeli, Lomaria, two very good Todea superba, and Trichomanes radicans, closely followed by Mr. Macdonald with fine specimens, such as Cibotium spectabile, Davallia polyantha, Nephrolepis davallioides, Goniophlebium appendiculatum, and Dicksonia antarctica. Mr. Thos. Clayton was placed third. In the class for eight exotic Orchids Mr. Cypher unfortunately was the only exhibitor, and was accorded the first prize for examples including a very good Epidendrum vitellinum, also Vanda suavis, Calanthe veratrifolia, Vanda suaveolens, Cypripedium Parishi, Oncidium macranthum, Cattleyas Mossiæ and Mendeli.

The groups of plants arranged for effect in a space of 450 square feet were decidedly the leading feature of the show. There were six entries, exceeding by one those of last year. Mr. Cypher was *facile princeps* with a splendid arrangement of Orchids and ornamental foliage plants with the indispensable Humea elegans. It was a beautiful arrangement and well worthy of the prize, £20. Mr. Finch was a good second with a somewhat similar display. The third position was occupied by Mr. Vause, and Mr. Macdonald was a very close fourth-prize man. Messrs. Tom B. Dobbs & Co., and J. E. Knight, both of Wolverhampton, were highly commended for two very creditable and attractive groups.

The groups shown by gentlemen's gardeners in this class were also marked by good taste in arrangement, and Mr. A. Cryer, gardener to J. A. Kendrick, Esq., Edgbaston, was worthily accorded the premier prize; Mr. R. Sharpe being placed second, with also a very good group; whilst Messrs. T. Clayton and Enoch Horton of Bescot were respectively third and fourth. Mr. Macdonald was the only exhibitor of six Orchids, and for which the second prize was awarded. Caladiums were represented by two entries, the first prize being awarded to Mr. T. Clayton, and the second to Mr. R. Sharpe. Exotic Ferns were, as in the open section, a prominent feature, and Mr. Macdonald took the lead with fine examples, the second and third prizes being respectively awarded to Messrs. T. Clayton and R. Sharpe.

For six stove and greenhouse plants, not less than three varieties in bloom, Messrs. T. Clayton, A. Cryer, and Macdonald were placed as in order named for creditable examples. Begonias were sparsely shown. For twelve plants Mr. A. Cryer and Mr. R. Sharpe were respectively awarded the first and second prizes for fair examples.

Roses were a very strong feature, the display being the largest ever seen here. The competition was extremely keen, as may readily be conjectured when such notable and large growers as Messrs. Harkness, Cant, and Perkins of Coventry are taken in account, and the four dozen boxes staged along one side of a long tent made an imposing scene. In the class for seventy-two blooms Messrs. Harkness were placed in the first position for the valuable prize of £7 10s., including £5 5s. presented by the Mayor of Wolverhampton, Alderman Craddock. There were so many blooms equally meritorious in the collection that it would be almost invidious to particularise them. The second prize went to Mr. B. R. Cant, Colchester, who was a close and excellent competitor, while the third and fourth prizes were awarded respectively to Messrs. R. Mack and Son and Cranston's Company, Hereford.

In the class for forty-eight blooms the positions were reversed, Mr. B. R. Cant taking the lead, closely followed by Messrs. Harkness and Sons, with Messrs. Perkins & Sons, Coventry, and Messrs. Townsend and Sons, Worcester, placed in the order named. With twenty-four distinct varieties, three trusses of each, Messrs. B. R. Cant, Harkness and Sons, J. Townsend & Sons, and Mr. C. Turner, Slough, were the respective winners. With twenty-four single blooms, Messrs. J. Townsend, J. Mattock, Oxford, and C. Turner were the successful exhibitors, whilst an extra prize was awarded to Messrs. Perkins & Sons, Coventry. For twelve distinct varieties of 1894, 1895, and 1896, Messrs. B. R. Cant and Perkins & Sons were the only exhibitors in a close run, the former firm having greater diversity of colour.

For twelve blooms of one dark coloured variety, Mr. B. R. Cant was awarded the premier prize with an excellent stand of Horace Vernet, the second prize being secured by Messrs. Townsend & Sons for a box of A. K. Williams. For twelve blooms, one light variety, Mr. B. R. Cant was placed first with a splendid box of Her Majesty, the second prize being secured by Messrs. Harkness with an excellent exhibit of Mrs. John Laing, and the third prize to Mr. J. Mattock for Comtesse de Nadaillac.

For twelve blooms of Teas, Mr. B. R. Cant was to the fore with a beautiful stand of distinct varieties, Messrs. J. Mattock and Townsend being respectively in the second and third positions. For the most decorative arrangement of Roses, Messrs. Perkins & Sons were worthily accorded the first prize of £5 for a most varied and elegant arrangement, the second prize being taken by Mr. J. Mattock, and the third by Messrs. Townsend & Sons.

In the class open to gentlemen's gardeners and amateurs only, thirty-six distinct varieties, single blooms, the Rev. J. H. Pemberton was placed first, and Mr. J. Egginton, Wolverhampton, second. For eighteen trusses of distinct varieties Mr. J. Egginton was placed first as the only exhibitor.

The miscellaneous cut flower and bouquet section was a very attractive one, and in the class for twelve bunches of stove and greenhouse flowers Messrs. Cypher, Jenkinson & Son, Newcastle, Staffs, and Mr. W. Vause were the respective winners with very rich and fresh blooms. Bouquets for the hand formed an imposing feature, Messrs. Perkins and Sons winning the premier prize with a beautiful and graceful arrangement of Odontoglossum Alexandræ and other Orchids chiefly, with Messrs. Jenkinson & Son, and Jones & Sons, Shrewsbury, respectively second and third competitors. For a bridal bouquet Messrs. Perkins were again to the front, with Messrs. Jenkinson & Son and Miss H. M. Stevens, Western Arcade, Birmingham, following. For a bridesmaid's bouquet Messrs. Perkins & Sons, Coventry, were represented by a lovely arrangement of Orchids chiefly, the second prize being awarded to Messrs. Jenkinson & Son, and the third to Miss H. M. Stevens for exquisite effects in this line.

For an arrangement of hardy border flowers, occupying a space not exceeding 12 feet by 3 feet, the first prize was awarded to Messrs. Harkness & Son, and the second and third prizes to Mr. W. F. Gunn, Birmingham, and Messrs. Barr & Sons, London, and forming altogether an attractive display. The dinner-table decorations were of a comparatively mediocre description, yet there was considerable merit observed in the first prize example by Miss H. M. Stevens, whilst Miss A. L. Vernon and Mr. W. Vause had heavier arrangements. For the most tasteful arrangement of Pansies and Violas there was only one competitor, Mr. M. Campbell, High Blantyre, who was awarded the first prize for a very good and striking arrangement. The remaining four classes were very well represented by other exhibitors, including Mr. Campbell, who took the leading position nearly throughout.

Carnations and Pinks formed an attractive feature, contributed to by several exhibitors. Sweet Peas were in strong force, and next to the Roses, if not equal to them, and were declared to be the largest and best exhibit of these popular flowers ever seen in this country. They were set up with good effect in the glasses and vases, but in some instances the effect would have been greatly enhanced had the respective rows been raised so as to present a better and more direct front to the spectator. In the class for an arrangement of Sweet Peas for effect, at least twenty varieties, the gold medal was won by Messrs. Jones & Son, Shrewsbury, with a highly meritorious exhibit; the silver medal being secured by Mr. V. B. Johnson, Tettenhall, Staffs; and the bronze medal by Mr. W. F. Gunn, Olton, near Birmingham. A magnificent collection of the best and newest varieties, remarkable for size, substance, and colour, was most effectively arranged by Mr. H. J. Eckford, Wem.

A very interesting and pleasing feature were the wild flower exhibits

by school children, which called forth the warm encomiums of the judges, and who found it no small difficulty to adjudicate thereon. A commendable feature in connection with the exhibiting of wild flowers was the offering of substantial prizes for collections of named flowers to children residing and attending public elementary schools in Wolverhampton. The name of each separate flower to be neatly written in ink on a white label, and attached by the competitor in the presence of a member of the Horticultural Committee on the show ground. The first prize (10s.) was awarded to Master H. Egginton, Wolverhampton, he being the only exhibitor.

The "Hawley" silver challenge cup (value £20) for a display of plants or floral decorations, arranged in a space not to exceed 200 square feet, was won, as it was last year, by Messrs. Dickson, Ltd., Chester, with a handsome display of Roses and herbaceous flowers.

Vegetables and Fruit.

There was not very strong competition in the classes for vegetables, but the quality was all that could be desired. In the competition for the prizes offered by Messrs. Webb & Sons, Stourbridge, for a collection of six distinct kinds of vegetables Mr. C. J. Waite, gardener to Col. Sir P. Talbot, Esher, Surrey, was worthily awarded the first prize for a very clean and shapely lot. His Market Favourite Carrots, Stourbridge Glory kidney Potatoes, Webb's Jubilee Tomatoes, Mammoth Cauliflowers, Webb's Reliance Onions, and Webb's Chancellor Peas, forming an ideal collection. The second prize was secured by Mr. J. Read, gardener to the Earl of Carnarvon, with also a meritorious stand, including very fine Webb's Goldfinder round Potatoes, Eclipse Cauliflowers, Jubilee Tomatoes, and Duke of Albany Peas.

In the class open to all England—presented by Messrs. Sutton and Sons, Reading, for the best collection of vegetables (£5), to occupy a space 6 feet by 4 feet—Mr. C. J. Waite was worthily awarded the prize for a collection containing about twenty-four varieties, he being the only exhibitor. In Messrs. Sutton & Sons' class for six distinct varieties, open to competitors residing within twenty miles of Wolverhampton, Mr. C. Brummell, gardener to H. H. France Hayhurst, Esq., took first honours with a remarkably fine assortment, the second and third prizes being secured by Mr. G. H. Bishop, gardener to Mrs. Wight Boycott, Wightwick Manor, and Mr. A. Cryer respectively, with also very good representations. For three dishes of Tomatoes there was only one exhibit, and the first prize was given to Mr. J. Read for very fine and smooth fruits.

Fruit was not so strongly represented as might have been expected; especially was this the case amongst Grapes. In the class of nine dishes the first prize fell to Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, for a Queen Pine, three bunches of fine Black Hamburghs (well coloured), three bunches of Muscat of Alexandria (fair in size, but lacking colour and ripeness), a large Hero of Lockinge Melon (very fine), Barrington Peaches (excellent), Violette Hâtive Peaches, Lord Napier Nectarines, Violette Hâtive ditto, and a very good dish of the Waterloo Strawberry. The second prize was secured by Mr. F. Harris, gardener to Lady H. Somerset, Ledbury, with also an excellent collection, including a grand Smooth-leaf Cayenne Pine, Black Hamburgh Grapes, three bunches of Muscat of Alexandria Grapes of very good colour and large in berry, very fine Bellegarde Peaches, fine Pitmaston Orange Nectarines, and Hales' Early Peaches, Violette Hâtive Nectarines, and large and beautifully coloured Bigarreau Napoleon Cherries; the third prize being awarded to Mr. T. Bannerman, gardener to Lord Bagot, Rugeley.

Grapes were a small section as compared with some previous occasions. For four bunches, distinct varieties, Mr. F. Harris was first with fine and large berried well coloured examples of Madresfield Court, Muscat of Alexandria, Black Hamburgh, and Foster's Seedling; the second prize going to Mr. J. Read for very good Black Hamburgh, Madresfield Court, a good bunch of fairly ripened Muscat of Alexandria, and a well ripened, large berried bunch of Buckland Sweetwater; the third prize fell to Mr. S. Brummell with a fair exhibit, in which was a compact and large well coloured berried bunch of Gros Maroc.

For two bunches of black Grapes Mr. J. F. Simpson, gardener to C. T. Mander, Esq., Tettenhall, was the only exhibitor, the second prize only being awarded for his specimens of Black Hamburghs, large in bunch and berry, but deficient in colour. The white Grape class was represented by Mr. S. Brummell with two bunches, large in berry, of Foster's Seedling, the second prize going to Mr. F. Harris for very good Foster's Seedling, and Mr. J. Read was placed third with fair Buckland Sweetwater.

For a dish of six Peaches, Mr. F. Harris, Mr. Goodacre, and the gardener to A. L. Vernon, Esq., Hilton Hall, were the respective winners with very good examples, and in the Nectarine class Mr. C. J. Waite, Mr. J. Read, and Mr. F. Harris were awarded the prizes as in the order named for fair sized and well coloured fruits. Strawberries were excellently shown, though not in great quantity. For three dishes, distinct varieties, Mr. T. Bannerman, Mr. J. F. Simpson, and Mr. F. Harris were the respective prizetakers, with very fine examples, comprising such as President, Sir C. Napier, Waterloo, Sir Joseph Paxton, and other good varieties.

Miscellaneous Exhibits.

A gold medal was awarded to Messrs. James Veitch & Sons, Ltd., Chelsea, for a highly attractive and superb collection of new and rare plants, including Caladiums, Rhododendrons, Javanico-jasminiflorum hybrids, and a fine specimen of the handsome-foliaged Heliconia illustris rubricaulis. A gold medal was also accorded to Messrs. J. H. White and Co., Worcester, for a very fine collection of hardy herbaceous flowers, and a silver-gilt medal was worthily bestowed to Messrs. Birkenhead, Sale, for a large collection of hardy Ferns.

Messrs. Jarman & Co., Chard, Somerset, took a silver medal for a collection of Roses, Sweet Peas, hardy herbaceous flowers, and vegetables; Messrs. Hewitt & Co., Solihull, a silver medal for a large collection of herbaceous flowers and Begonias; Messrs. Thomson and Sons, Birmingham, a bronze medal for a collection of Gloxinias, Carnations, Bouvardias, and Ferns; Messrs. Jones & Son, Shrewsbury, a bronze medal for a collection of decorative floral devices, &c.; Messrs. W. Clibran and Co., Oldfield Nurseries, a bronze medal for a collection of Violas and table plants. Mr. Richard Lowe, Wolverhampton, was awarded a silver medal and a certificate of merit for collections of decorative plants and a group arranged for effect.

Mr. Robert Sydenham, Birmingham, a bronze medal for table and rustic adornments. Miss Stevens, Birmingham, a bronze medal for a collection of buttonholes, sprays and wreaths. Messrs. Dobbie & Co., Rothesay, a bronze medal for an interesting collection of their specialities. Messrs. Rowe & Sons, Worcester, a bronze medal for a large collection of hardy flowers, and Messrs. Tom Dobbs & Co., Wolverhampton, were accorded a silver medal for a fine collection of hardy herbaceous flowers. Mr. E. Murrell, Portland Nurseries, Shrewsbury, was awarded a silver medal for a fine collection of decorative Roses.

NORWICH.—July 15th.

The weather on Thursday last, when the National Rose Society held its Northern Exhibition in conjunction with the Norfolk and Norwich Horticultural Society, was very bright, and the sun shone so intensely that ere mid-day was past many of the Roses were commencing to go. But the tent in which the major portion of the Roses were staged was exceptionally cool, so that the flowers fared better than they otherwise would have done. The show was held in the grounds of Carrow Priory, Trowse, by the kind permission of J. J. Colman, Esq., and it would be difficult to find a more suitable place for such a purpose.

On the whole the display can only be termed a good one. It would probably have been far better but for the intense sun heat to which the blooms had been subjected for the few previous days. Several of the best trade and amateur growers staged flowers which, in some cases, were slightly past their best. A few blooms of exceptionally good quality were seen, as for example, Mr. Merryweather's Niphetos, which secured a medal. This was a magnificent flower—indeed it was probably one of the finest of the variety that has ever been shown. Mr. Lindsell followed up his successes at other shows by securing all the chief prizes with extraordinary persistency. Messrs. B. R. Cant, Harkness & Son, F. Cant & Co., and D. Prior & Son were strongly represented in various classes, and divided the best of the prizes between them.

In some of the classes the competition was poor, while in others it was very strong. There were exhibits in almost all the classes scheduled, but in some cases the flowers were not up to the mark. The arrangements were well carried out by the local society, and as a rule there was no difficulty in finding any particular class, and with such a light it was of course easy to see every bloom. Below we give a list of the prizewinners with the names of the varieties staged in the first-prize exhibits where these could be got.

Nurserymen's Classes.

Most of the interest in this section was centred in the class for thirty-six distinct, one truss of each, as with the first prize went the Jubilee trophy. Mr. B. R. Cant, Colchester, added to his already long list of victories by securing the premier position with a stand of fresh, clean, even flowers well staged. The varieties were Duchesse de Morny, A. K. Williams, Mrs. John Laing, Her Majesty, Alfred Colomb, Marchioness of Londonderry, Gustave Piganeau, Maman Cochet, Madame Crapelet, Marchioness of Dufferin, Susanne Marie Rodocanachi, Beauty of Waltham, Muriel Grahame, Countess of Rosebery, Ernest Metz, Comte de Raimbaud, Helen Keller, Madame Eugène Verdier, Madame de Watteville, Salamander, Pride of Waltham, Marie Baumann, The Bride, Innocente Pirola, Auguste Rigotard, Senateur Vaisse, Bridesmaid, John Stuart Mill, Comtesse de Nadaillac, Madame Delville, Ethel Brownlow, Ulrich Brunner, Catherine Mermet, and Marie Verdier. The second position was accorded to Messrs. Harkness & Son, Bedale, who also staged splendidly. Particularly good were A. K. Williams, Earl of Dufferin, Star of Waltham, Duchess of Bedford, Comtesse Ludre, Madame Gabriel Luizet, Madame Cusin, Grand Mogul, and Gustave Piganeau. Messrs. Paul & Son, Old Nurseries, Cheshunt, were third.

In the class for seventy-two distinct single trusses, Mr. B. R. Cant again demonstrated his superiority by taking the first place. The stand was a capital one, despite the fact that a few of the flowers were past their best. The varieties represented comprised A. K. Williams, Susanne Marie Rodocanachi, Madame Clemence Joigneaux, Ernest Metz, Paul Neron, Madame Gabriel Luizet, Horace Vernet, Her Majesty, Countess of Rosebery, Marchioness of Dufferin, Ulrich Brunner, Souvenir d'un Ami, Camille Bernardin, Duchesse de Morny, Beauty of Waltham, Madame Eugène Verdier, Gustave Piganeau, Laurence Allen, Earl of Dufferin, Marguerite de St. Amand, Madame Crapelet, Marchioness of Londonderry, Le Havre, Edouard André, Fisher Holmes, Ellen Drew, Comtesse de Paris, Madame de Watteville, Charles Lefebvre, Lady Mary Fitzwilliam, Mons. E. Y. Teas, Madame Joseph Bonnaire, Comtesse de Ludre, Jean Soupert, Alfred Colomb, Pride of Waltham, Comtesse d'Oxford, Star of Waltham, Clio, Etienne Levet, Madame Delville, Reynolds Hole, Pride of Reigate, Robert Lebaudy, White Lady, Duke of Teck, Mrs. John Laing, Thomas Mills, Madame Cusin, Eclair, The Bride,

Victor Hugo, Souvenir de S. A. Prince, Dr. Andry, Hellen Keller, Auguste Rigotard, Jeanie Dickson, Bridesmaid, Merveille de Lyon, Prince Arthur, Innocente Pirola, Charles Lamb, Marchioness of Downshire, Comte de Raimbaud, Muriel Grahame, Marie Baumann, Ethel Brownlow, Duke of Wellington, Maman Cochet, Charles Darwin, and John Stuart Mill. The second and third positions were assigned to Messrs. Harkness & Son and Paul & Son in the order given.

There were apparently only two entries in the class for thirty-six distinct varieties, three blooms of each, and once again Mr. B. R. Cant took pride of place over Messrs. Harkness & Son. The winner staged A. K. Williams, Madame Eugène Verdier, Earl of Dufferin, Marchioness of Londonderry, Madame Crapelet, Marguerite de St. Amand, Duke of Fife, Helen Keller, John Stuart Mill, Mrs. John Laing, Etienne Levet, Duchesse de Morny, Ulrich Brunner, Marchioness of Downshire, Alfred Colomb, Ethel Brownlow, Gustave Piganeau, Her Majesty, Horace Vernet, Madame Cusin, Dupuy Jamain, Marie Verdier, Camille Bernardin, Madame Gabriel Luizet, Le Havre, Ernest Metz, Comte de Raimbaud, Marchioness of Dufferin, Duke of Teck, Countess of Rosebery, Fisher Holmes, Susanne Marie Rodocanachi, Charles Lefebvre, Madame de Watteville, Comtesse d'Oxford, and Pride of Waltham. Conspicuous in Messrs. Harkness & Son's stand were The Bride, Madame Gabriel Luizet, Dupuy Jamain, Etienne Levet, Duchesse de Morny, Niphetos, Ethel Brownlow, and Helen Keller.

Messrs. D. Prior & Son, Myland Nurseries, Colchester, secured the chief award in a class for thirty-six distinct single trusses, showing several in highly creditable form. There were Mrs. John Laing, A. K. Williams, Maman Cochet, Ulrich Brunner, Innocente Pirola, Alfred Colomb, Madame de Watteville, Duc d'Orleans, Hon. Edith Gifford, Susanne Marie Rodocanachi, Pride of Waltham, Gustave Piganeau, Marchioness of Londonderry, François Michelon, Dr. Andry, Madame Cusin, Marie Verdier, Queen of Queens, Star of Waltham, Her Majesty, Charles Darwin, Ernest Metz, Charles Lefebvre, The Bride, Victor Hugo, Maréchal Niel, Horace Vernet, Bridesmaid, Louis Corbie, Marie Van Houtte, Reynolds Hole, Medea, Marquis de Litta, Kaiserin Augusta Victoria, Mons. E. Y. Teas, and Etienne Levet. Messrs. J. Townsend and Son, Worcester, took the second prize; and Messrs. J. Burrell and Sons, Howe House Nurseries, Cambridge, the third.

For eighteen trebles, distinct, Messrs. D. Prior & Son were again to the fore with an even exhibit containing the following varieties:—A. K. Williams, White Lady, Alfred Colomb, Marchioness of Londonderry, Comte de Raimbaud, Mrs. John Laing, Star of Waltham, Pride of Waltham, Victor Hugo, Susanne Marie Rodocanachi, Comtesse de Nadaillac, Horace Vernet, Madame Hoste, Ernest Metz, Fisher Holmes, Maman Cochet, Gustave Piganeau, and Innocente Pirola. In the second prize box, staged by Messrs. J. Townsend & Son, were noted Susanne Marie Rodocanachi, Victor Verdier, Kaiserin Augusta Victoria, The Bride, and Star of Waltham. Mr. Charles Turner, Royal Nurseries, Slough, was third.

Amateurs' Classes.

Corresponding in importance with the first class mentioned in the nurserymen's section was the amateurs' trophy class for twenty-four, distinct, single trusses, in which E. B. Lindsell, Esq. (who might well be named the invincible), Hitchin, was an excellent first with a charming stand. The varieties were Earl of Dufferin, Comtesse de Nadaillac, Beauty of Waltham, Maman Cochet, Gustave Piganeau, Merveille de Lyon, Susanne Marie Rodocanachi, Her Majesty, Madame Cusin, Charles Lefebvre, The Bride, Horace Vernet, Muriel Grahame, A. K. Williams, Madame de Watteville, Alfred Colomb, Marie Baumann, Catherine Mermet, Madame Victor Verdier, Duke of Wellington, Innocente Pirola, Duchesse de Morny, and Souvenir d'Elise Vardon. The Rev. J. H. Pemberton, Havering-atte-Bower, was a splendid second. Helen Keller, A. K. Williams, Dupuy Jamain, Charles Lefebvre, Comte de Raimbaud, Marshall P. Wilder, and Horace Vernet were noticeable in this stand. H. P. Machin, Esq., Gateford Hill, Worksop, and W. Boyes, Esq., Derby, were placed equal third.

The "open to all amateurs" class for thirty-six distinct single trusses was well won by E. B. Lindsell, Esq., the Rev. J. H. Pemberton and H. V. Machin, Esq., following as here named. The first prize exhibit contained Charles Lefebvre, Duchesse de Morny, Duke of Connaught, Merveille de Lyon, Susanne Marie Rodocanachi, Her Majesty, Dupuy Jamain, Mrs. John Laing, Beauty of Waltham, Marchioness of Dufferin, Earl of Dufferin, Marchioness of Londonderry, Dr. Andry, Marie Baumann, Helen Keller, Victor Hugo, Catherine Mermet, Marie Rady, Innocente Pirola, Sir Rowland Hill, The Bride, Horace Vernet, Muriel Grahame, A. K. Williams, Prince Arthur, Souvenir d'Elise Vardon, Abel Carrière, Ethel Brownlow, Gustave Piganeau, Madame de Watteville, Madame Haussmann, Madame Cusin, Fisher Holmes, Comtesse de Nadaillac, Duchess of Bedford, and Ernest Metz. In Mr. Pemberton's box Victor Hugo, A. K. Williams, Dupuy Jamain, and Countess of Rosebery were conspicuous.

Precisely the same position was maintained in the class for eight distinct trebles, as in the one immediately preceding. Mr. Lindsell's stand was composed of Horace Vernet, Madame de Watteville, A. K. Williams, The Bride, Muriel Grahame, Charles Lefebvre, Alfred Colomb, and Her Majesty.

In a class open only to growers of less than 2000 plants, for eighteen distinct single trusses, O. G. Orpen, Esq., West Bergholt, Colchester, was a capital first prizewinner. The stand comprised Her Majesty, Maman Cochet, Kaiserin Augusta Victoria, Mrs. John Laing, Maréchal Niel, Muriel Grahame, Horace Vernet, Catherine Mermet, François Michelon, Souvenir d'un Ami, Comtesse de Nadaillac, Helen Keller, Ernest Metz, Madame de Watteville, Souvenir de S. A. Prince, A. K. Williams, Sylph, and The Bride. S. S. Berger, Esq., Stevenage, was a fair second, and the Rev. A. Cecil Johnson, Capel St. Mary, third. The first award in this class took the form of a piece of plate, value 5 guineas, presented by the Mayor of Norwich.

Mr. M. Whittle, Leicester, was a splendid first in the class for twelve distinct varieties, open only to growers of less than 1000 plants. He staged Her Majesty, Gustave Piganeau, Marchioness of Londonderry, Susanne Marie Rodocanachi, Mrs. John Laing, Ulrich Brunner, Comtesse de Nadaillac, Victor Hugo, Maréchal Niel, Earl of Dufferin, Maman Cochet, and Charles Darwin. Mr. George Moules was a close second, and Mr. J. Bateman, Highgate, third.

In the class for six distinct single trusses, open only to growers of less than 500 plants, Mr. R. W. Bowyer, Haileybury, was first with Horace Vernet, Mrs. John Laing, Madame Cusin, Caroline Testout, Princess of Wales, and Madame Hoste. The second prize went to Mr. J. Mallender, gardener to Mrs. Mellish, Hodsock Priory, Worksop, and the third to Mr. H. P. Landon, Brentwood. For four trebles the prizewinners were Messrs. O. G. Orpen, S. S. Berger, and M. Whittle.

H. V. Machin, Esq., with Her Majesty in splendid form was first for nine single trusses any Rose except Tea or Noisette. E. B. Lindsell, Esq., was second, and the Rev. J. H. Pemberton third, each staging A. K. Williams. For six single trusses of any H.P. or H.T., Mr. H. P. Landon was to the front with Mrs. John Laing, followed by Mr. H. T. Edwards, Derby, with Her Majesty, and C. A. Fellowes, Esq., Shottesham, with Ulrich Brunner. The Rev. J. H. Pemberton was first for six new Roses, distinct, single trusses, with Marquis de Litta, Helen Keller, Ellen Drew, Mrs. R. G. Sharman Crawford, Clio, and Madame Joseph Courbet. H. V. Machin, Esq., was second, and J. Bateman, Esq., third.

Tea and Noisette Section.

In this section, both in the nurserymen's and amateurs' classes, there were many lovely blooms staged, but the numbers were not quite so large as we should like to have seen. The flowers were of good shape, and the colouration in some cases was of exquisite delicacy.

There was one class open to all comers for twelve Teas or Noisettes, three blooms of each variety. Mr. Henry Merryweather, Southwell, Notts, was a very decided first, his stand containing excellent blooms. The varieties were Niphetos, Ethel Brownlow, Ernest Metz, Maman Cochet, Innocente Pirola, Bridesmaid, Comtesse de Nadaillac, The Bride, Catherine Mermet, Golden Gate, Madame de Watteville, and Souvenir d'Elise Vardon. Mr. B. R. Cant was a creditable second with Madame Cusin, Muriel Grahame, Comtesse de Nadaillac, The Bride, and Bridesmaid as his best blooms. Messrs. F. Cant & Co., Colchester, were a good third.

Nurserymen.—Messrs. F. Cant & Co. staged a stand of great beauty comprising blooms of fine quality in the class for eighteen distinct single trusses. The varieties represented were Madame Cusin, Souvenir d'Elise Vardon, Ernest Metz, The Bride, Madame de Watteville, Caroline Kuster, Perle des Jardins, Comtesse de Nadaillac, Innocente Pirola, Maman Cochet, Etoile de Lyon, Madame Angele Jacquier, Madame Hoste, Catherine Mermet, Maréchal Niel, Bridesmaid, and La Boule d'Or. Mr. B. R. Cant was assigned the second position, Ernest Metz, Ethel Brownlow, Souvenir d'Elise Vardon, Innocente Pirola, Sylph, Madame de Watteville, and Francisca Kruger being noticeable in his exhibit. Messrs. D. Prior & Son were third.

For twelve Teas or Noisettes, distinct, one truss of each, Mr. Henry Merryweather was a splendid first with an excellent stand. The varieties were Madame de Watteville, Niphetos, Bridesmaid, Innocente Pirola, Elise Fugier, Comtesse de Nadaillac, Ernest Metz, The Bride, Maman Cochet, Madame Cusin, Madame Hoste and Catherine Mermet, all of which were fresh and well coloured. Mr. George Prince, Oxford, was second with Ernest Metz, Madame Cusin, Catherine Mermet, and The Bride well represented. Mr. J. Mattock, New Headington, Oxford, was third.

Amateurs.—E. B. Lindsell, Esq., secured the premier award in the class for twelve distinct single trusses, open to all amateurs. His stand contained Comtesse de Nadaillac, Catherine Mermet, Madame de Watteville, The Bride, Madame Cusin, Ernest Metz, Maman Cochet, Innocente Pirola, Souvenir d'Elise Vardon, Ethel Brownlow, Madame Hoste, and Caroline Kuster. C. J. Grahame, Esq., Leatherhead, was a very creditable second. Ethel Brownlow, Madame Cusin, Muriel Grahame, and Princess of Wales were good in this stand. O. G. Orpen, Esq., was placed third.

E. B. Lindsell, Esq., was again successful in securing the first prize in the class for nine blooms of any Tea or Noisette with a lovely stand of Comtesse de Nadaillac. The blooms were not large, but of exquisite colour and perfectly fresh. C. J. Grahame, Esq., with the same variety took the second prize, and H. V. Machin, Esq., the third, with Maman Cochet in good order.

There was a class for nine distinct Teas or Noisettes, one truss of each, which was open only to those who cultivate less than 500 plants. The Rev. F. Page Roberts was first with Comtesse de Nadaillac, Madame Hoste, Maman Cochet, Anna Ollivier, Cleopatra, Ethel Brownlow, Golden Gate, Souvenir de S. A. Prince, and Caroline Kuster. E. Mawley, Esq., was second, and the Rev. J. H. Pemberton third.

R. W. Bowyer, Esq., was first for six distinct single trusses, open only to growers of less than 200 Teas and Noisettes, with Maman Cochet, Catherine Mermet, Comtesse de Nadaillac, Innocente Pirola, The Bride, and Madame de Watteville. H. P. Landon, Esq., was placed second, and S. S. Berger, Esq., third.

C. J. Grahame, Esq., was well ahead in an extra class for six Teas or Noisettes distinct, three blooms of each. The varieties were Maréchal Niel, The Bride, Maman Cochet, Innocente Pirola, Muriel Grahame and Comtesse de Nadaillac. The second and third prizes were adjudged to Messrs. H. V. Machin and O. G. Orpen as named. H. P. Landon was first for six blooms of any one Tea or Noisette, with good specimens of Innocente Pirola, the Rev. F. Page Roberts being second, and S. S. Berger, Esq., third.

Open Classes.

Messrs. Paul & Son were placed first in the class for twelve new Roses, distinct, one truss of each, with T. B. Haywood, Clio, Captain Hayward, Bladud, Mrs. W. J. Grant, Sylph, Haileybury, Marquis de Litta, Muriel Grahame, Helen Keller, Bacchus, and one other of which we could not read the name. Mr. B. R. Cant took the second prize.

The last-named exhibitor, with beautiful examples of The Bride, was first for twelve single trusses of any white Rose, followed by Messrs. J. Townsend & Son with the same variety, and Mr. A. G. Green, Colchester, with Innocente Pirola.

For twelve single trusses of any yellow Rose the three prizewinners—Messrs. J. Townsend & Son, F. Cant & Co., and George Prince—staged Comtesse de Nadaillac, all in good form. For twelve of any light Rose, other than Her Majesty, Mr. B. R. Cant was first with Mrs. John Laing, Messrs. D. Prior & Son second with the same variety, and Messrs. F. Cant & Co. third with Madame de Watteville. For the same number of blooms of any crimson Rose Messrs. F. Cant and Co. were first with A. K. Williams, Messrs. J. Townsend & Co. second with Horace Vernet, and Messrs. Harkness & Son third with A. K. Williams. For twelve blooms of Her Majesty the successful exhibitors were Messrs. Paul & Son, H. V. Machin, and Harkness and Son, in the order given.

Garden Roses.

In the amateurs' class for twelve bunches of garden Roses, H. V. Machin, Esq., was a grand first, followed by O. G. Orpen, Esq., who staged a charming collection. The first prize stand contained Crimson Rambler, The Pet, Wm. Allen Richardson, Madame Pernet Ducher, Mignonette, Macrantha, Bardou Job, Perle d'Or, Red Damask, Anna Maria de Montravel, L'Ideal, and Bennett's Seedling.

In the open class for eighteen bunches of Garden Roses, distinct, Messrs. Paul & Son were first. The varieties were Camoens, Wm. Allen Richardson, Crimson Rambler, Bennett's Seedling, Madame Pernet Ducher, L'Ideal, Marquis de Salisbury, Gustave Regis, Madame Pierre Cochet, Madame C. Guinnoiseau, Perle d'Or, Ma Capucine, Mignonette, Homère, Alister Stella Gray, Mons. Desir, and Blanche Moreau. Mr. C. Turner was second; and Mr. J. Mattock third.

For a display of Roses, arranged on a space not less than 6 feet by 3 feet or more than 12 feet by 3 feet, Mr. Geo. Prince was an easy first with a charming exhibit. Dr. Osborne, Old Calton, was second; and Mr. A. G. Green third.

Medal Roses.

The silver medals given by the Society for the best Roses in the Show were taken by Mr. H. Merryweather with Niphetos, and Messrs. Harkness & Son with Earl of Dufferin in the nurserymen's section; and Mr. O. G. Orpen with Muriel Grahame, and S. S. Berger, Esq., with Mrs. John Laing in the amateurs' classes.

Local Classes.

In addition to the several classes in which the National Rose Society offered prizes there was a section under the auspices of the local society. In this the exhibits were staged in a separate tent. The Roses were, as might naturally be expected, very much inferior in quality to those in the other division; in fact, the display was only relieved from mediocrity by the contributions of the Rev. A. Foster Melliar and one or two others who staged some handsome blooms. There were upwards of a dozen classes, particulars of which we are unable to give owing to pressure on our space; but besides the reverend gentleman named above, we noticed amongst the prizewinners the Rev. A. L. Fellowes, the Rev. H. Berners, the Rev. F. Page Roberts, and Messrs. C. A. Fellowes, T. C. Blofield, Colonel Rous, W. H. Hammond, B. E. Fletcher, W. H. Elsum, and D. C. Warnes. Besides the Roses there were classes for plants, hardy and greenhouse flowers, vegetables and fruits, and many exhibits of a highly meritorious character were staged.

There were a few miscellaneous stands not for competition which included Begonias, Ferns, vegetables and sundries from Messrs. Daniels Bros., Norwich; hardy flowers from Messrs. Paul & Son, Cheshunt; Sweet Peas from Mr. J. Green, Dereham; Roses from Messrs. W. Paul and Son, Waltham Cross; and Lilies of the Valley from Mr. J. Jannoch, Dersingham.

The northern Exhibition of the National Rose Society, which was held on the 15th inst., in conjunction with the Norfolk and Norwich Horticultural Society, was a most successful one. The total number of exhibition Roses staged in the joint show amounted to 3590, which is 500 more than the average for the previous five northern shows, and greater than at any similar exhibition of the Society, with the exception of those held at Birmingham in 1890, at Chester in 1892, and at Derby in 1895. There were in all exactly fifty exhibitors and 220 exhibits. Arranging the latter according to the number contributed by each county they come out as follows:—Norfolk 55 exhibits, Essex 46, Herts 32, Suffolk 23, Notts 15, Oxford 9, Surrey 8, Derby 7, Worcester 7, Cambridge 4, Yorkshire 4, Leicester 3, and Middlesex 3. Nearly 7000 persons visited the Show, which is a record attendance for a summer exhibition of the local society.—E. M., *Berkhamsted.*

NATIONAL VIOLA SOCIETY.—July 17th.

The second annual exhibition of this Society was held on Saturday, 17th inst., in the grounds of the Royal Botanic Society. Taken as a whole the show was rather smaller than usual, but the quality was above the average. The weather for the past few weeks has been so trying to the flowers in the south that many exhibitors could not stage a flower. The Pansies all came from north of the Tweed, and a brave show was made. The southern growers continue to hold their own in the Viola section, the strongest stands coming from amateurs in the neighbourhood of London.

In the class for forty-eight sprays of Violas, distinct varieties, Mr. W. Baxter of Woking secured the gold medal. The collection embraced all the leading kinds. A. J. Rowberry, Endymion, Princess Louise, Commodore, Wm. Haig, Duchess of Fife, Marchioness, and Florizel were the most conspicuous. Mr. John Forbes, Hawick, N.B., secured the second place with a brighter display, but the long journey had evidently been too much for some of the flowers. An innovation was made in the class for forty-eight bunches of Pansies, distinct varieties, and the effect was far better than can be obtained by the ordinary method of staging these flowers. Mr. M. Campbell, Blantyre, N.B., was easily first, and secured the gold medal for the best exhibit of Pansies. The blooms were bright, fresh, and of good substance. Messrs. Isaac House & Son, Coombe Nurseries, Westbury-on-Trym, Bristol, received the second award. Third, Mr. J. Forbes, Hawick.

The class for twenty-four Fancy Pansies, distinct varieties, brought out a strong team of exhibitors, Mr. M. Campbell taking first place. His best blooms were Colonel Buchanan, Mrs. Wm. Steel, Bernard Doulton, Mrs. Maundril, and John Gramm. Second, Mr. J. Smellie, Busby, N.B., with a stand almost equal in every respect, being only one point behind. Annie Ross, Tom Walters, Mrs. W. Watson, Mr. P. Crosbie, and Valkyrie were his best blooms. Third, Mr. Jas. Maxwell, Dalton Newton, N.B. Twelve Fancy Pansies were also well represented, Messrs. Smellie, Campbell, and Maxwell taking the cards in the order named. Show Pansies were weak, and call for no comment. In the class for twenty-four sprays of Violas Mr. J. Smellie secured first place. His best sprays were Dorothy, A. J. Rowberry, Lily Barron, and Stobhill Gem. Mr. M. Campbell second; Messrs. House & Son third. The minor classes were well filled, but were a repetition of the larger classes, the exhibitors in most cases being the same.

In the amateur classes Mr. R. T. Dougall, Walthamstow, took chief honours, and in fact staged the best Violas throughout the show. Mr. J. J. Sheldon, Woodford, was also in fine form. The President's prize for six growing plants was awarded to Mr. D. B. Crane, with a very fine basket. The clumps were large, fresh, and healthy looking. Second, Messrs. House & Son. The Viola is not adapted for this method of cultivation, its true home being in the border or beds. Eighteen distinct Violas in glasses, without any wiring, brought out a pretty display, Mr. A. J. Rowberry, Woodford, taking first honours with a fine even lot. The blooms kept wonderfully fresh and bright throughout the entire day, and contrasted favourably with the sprays that were looking very forlorn during the afternoon. Messrs. Dobbie & Co., Rothesay, staged a fine display of sixty sprays.

First-class certificates were awarded to Fancy Pansy John Menzies, from Mr. M. Campbell; to Viola Jas. P. Robertson, rosy purple, from Mr. John Forbes; White Empress, from Messrs. J. House & Son, and to Viola Endymion, lemon yellow, from Mr. W. Baxter.

NATIONAL CARNATION AND PICOTEE.—July 21st.

The southern section of the National Carnation and Picotee Society held its annual exhibition in the Royal Botanic Society on Wednesday. Though many flowers of excellent quality were exhibited the display made was not a good one, owing to the system of staging adopted. The time at our disposal precludes a full report of the show being given. We therefore name the prizewinners in a few of the chief classes only.

The class for twenty-four distinct bizarres and flakes was won by Mr. C. Turner, Slough, with an even stand of almost perfect flowers. Mr. M. Rowan, Clapham, was a capital second, and Mr. J. Douglas, Ilford, third. For twenty-four distinct selfs, Mr. C. Blick was first for a superb exhibit, Mr. C. Turner being second, and Mr. J. Douglas third.

Mr. C. Phillips, Bracknell, staged twelve beautiful flowers in the class for a dozen bizarres and flakes, distinct. Messrs. Thomson & Co., Birmingham, were second, and Mr. A. J. Saunders, Cobham, third. Mr. A. R. Brown, Handsworth, secured the premier award for six distinct, followed by Mr. W. Galston, jun., Woolston, and Mr. T. A. Brill in the order named.

Mr. C. Turner went ahead for twenty-four Fancies. The flowers were of good form and beautifully coloured. Mr. J. Douglas was second, and Mr. J. Walker, Thame, third. For twelve Fancies Mr. C. Phillips was first, and Mr. G. Chaundy, New Marston, second.

Mr. C. Turner was again first for twenty-four white-ground Picotees with a chastely beautiful exhibit. Mr. J. Douglas was second, and Mr. M. Rowan third. For twelve Messrs. Thomson & Co. were first, Mr. C. Chaundy second, and Mr. C. Phillips third. Messrs. A. R. Brown, T. A. Brill, and A. Greenfield were the most successful competitors for six white-ground Picotees. For twelve yellow-ground Picotees Mr. C. Blick was a splendid first, Mr. J. Douglas second, and Mr. C. Phillips third.

Mr. E. Colley Sharpen, Bedford, was to the front for twelve selfs, distinct; Mr. C. Phillips was second; and Messrs. Thomson & Co. third. For twelve distinct, shown with a spray of foliage, Mr. E. Charrington was first; Mr. G. G. Sundden second; and Mr. H. Fagents third.

For a group of Carnations, arranged for effect in a space not exceeding 30 square feet, Mr. J. Douglas was first as the only competitor. For a larger group Mr. C. Blick, gardener to M. R. Smith, Esq., Hayes, was first, followed by Mr. C. Turner, both staging well, though the first named plants were too packed.

Mr. Jas. Douglas, Great Bookham, sent a collection of flowers comprising many of the best well-known and new varieties. Messrs. J. Veitch & Sons, Ltd., sent two boxes of beautiful flowers of the leading varieties. Mr. E. F. Hopper, Hoddesdon, sent a few flowers, but none of very great merit; as did Messrs. W. Cutbush & Sons, Highgate, but some of these were very good.

FRITILLARIA ARMENA.

AMONG the dwarf-growing Fritillarias the species depicted in the illustration (fig. 13) occupies a prominent place. As the specific name implies, F. armena is a native of Armenia, and was introduced in 1878, but it is not generally well known in gardens. It is a charming little plant, growing about 6 inches in height. The flowers are brownish purple, and, as will he seen by referring to the woodcut, are small, campanulate, and slightly drooping. They are usually produced in April. There is a yellow form of this species named F. a. fusco-lutea. This was introduced in 1887, and is a native of Smyrna. F. armena can be grown in sheltered positions on a rockery or horder, or in pots in a cool greenhouse.

THE YOUNG GARDENERS' DOMAIN.

CULTIVATION OF THE MELON.

(*Continued from page* 60.)

As the roots penetrate through the ridge layers of fresh warmed compost should be added, doing this whenever the roots are visible. When top-dressing after the fruits are set a small quantity of artificial manure may be added with advantage. If each plant is required to carry four Melons allow three side shoots to grow. These should start from near the hase of the plant. Some growers stop their plants, so that they will hreak more freely; but we find no necessity for this, as the side shoots grow rapidly, reaching the top of the trellis with the main stem. When they have extended to the height desired hoth the main stem and side shoots are stopped, or as they may be now called the "four stems." Laterals are then produced, and these pinched at the second pistillate or fruit-hearing flower. When a sufficient number of these flowers are open they are fertilised about midday, when the pollen is dry. After a good set has heen obtained the fruits are thinned, only one being allowed on a stem. Those which remain should be of an equal size, for if otherwise they are very difficult to manage, for some of them will be netting when others are still swelling, some stems consequently requiring very little water, while others need a copious supply. Again, some fruits may he ripening, and need a minimum quantity of water, when others are in a green state and would suffer by the reduced supply. After the fruits have set remove all sub-laterals and superfluous growths, leaving only the main leaves.

Some growers follow a different method of training to the one described. The main stem is allowed to extend to the required height, and is then stopped, all side shoots being also stopped at the second pistillate flower. When the set has been obtained the fruits are thinned out to four on a plant. This method sometimes answers, but it is often found difficult to get the fruits equal in size, as the sap flows to the Melon furthest from the base, causing it to swell faster than those which are lower down.

After thinning the fruit, those which remain should be tied up, a short distance from the trellis, with a piece of matting, passing it round the stalk near the fruit. Afterwards the fruit will need something to rest upon. Small pieces of board, or wicker baskets, made for the purpose, fastened to the trellis with pieces of string, may be used. Nets, made for the purpose, can he obtained from nurserymen and seedsmen, and these are preferable to boards and baskets. Cut the Melons before they are fully ripe, and place them in a dry, airy room.—ELVEDEN.

MEANS AND MODES OF PROPAGATING PLANTS.

(*Continued from page* 60.)

RETURNING to the consideration of the root of the plant, it must be remembered that it is not always the portion of the plant that happens to grow underground that is really its root. We are accustomed to call Potatoes, Parsnips, Carrots, Onions and Beetroots, root crops, because the parts of them that are eaten grow under the earth's surface, or nearly so; hut in reality the parts of the Potato that we use as food are tubers; the Carrot, Parsnip, and Beetroot, as well as the Dahlia, are tuberoids, and the Onion, in common with the Lily and the Hyacinth, is a bulb.

What, then, is the root? The root or roots of a plant are offsets from that portion of it which is within the soil in the form of threads or filaments, terminating in soft organs called spongioles, through which moisture and the various elements that combine to form the structure of the plant are absorbed from the earth to be carried upward to the extremities of the branches.

In the Onion and all bulbs the roots are not the bulbous portions which are produced and matured either above or below the surface of the soil, but the circle of fibres which issue from the edges at the bottom of the bulb. In the Potato the tuber, rich in starch and nutritive matter, is not the root, but the roots are the string-like fibres issuing from the tuher, through which the food stored up within it has been gathered from the soil. The real roots of the Parsnip, the Carrot, and the Beetroot are the thread-like fibres which issue from the fleshy tuberous roots on all sides, and especially at the extremity, which is commonly called the tap root.

We are now in a better position to understand the various natural means by which the propagation of plants is effected. The junction of root and stem is usually called the collar, and in planting due regard should be had to keeping the collar in its proper position, for if it be too low the portion of the stem that is buried will be liable to canker, especially in the case of worked trees, where the junction is close to the ground; and if it he too high a portion of the plant that ought to be below ground will he above it, and will suffer from the exposure. This, however, as we have seen, is not the case with every plant, and we

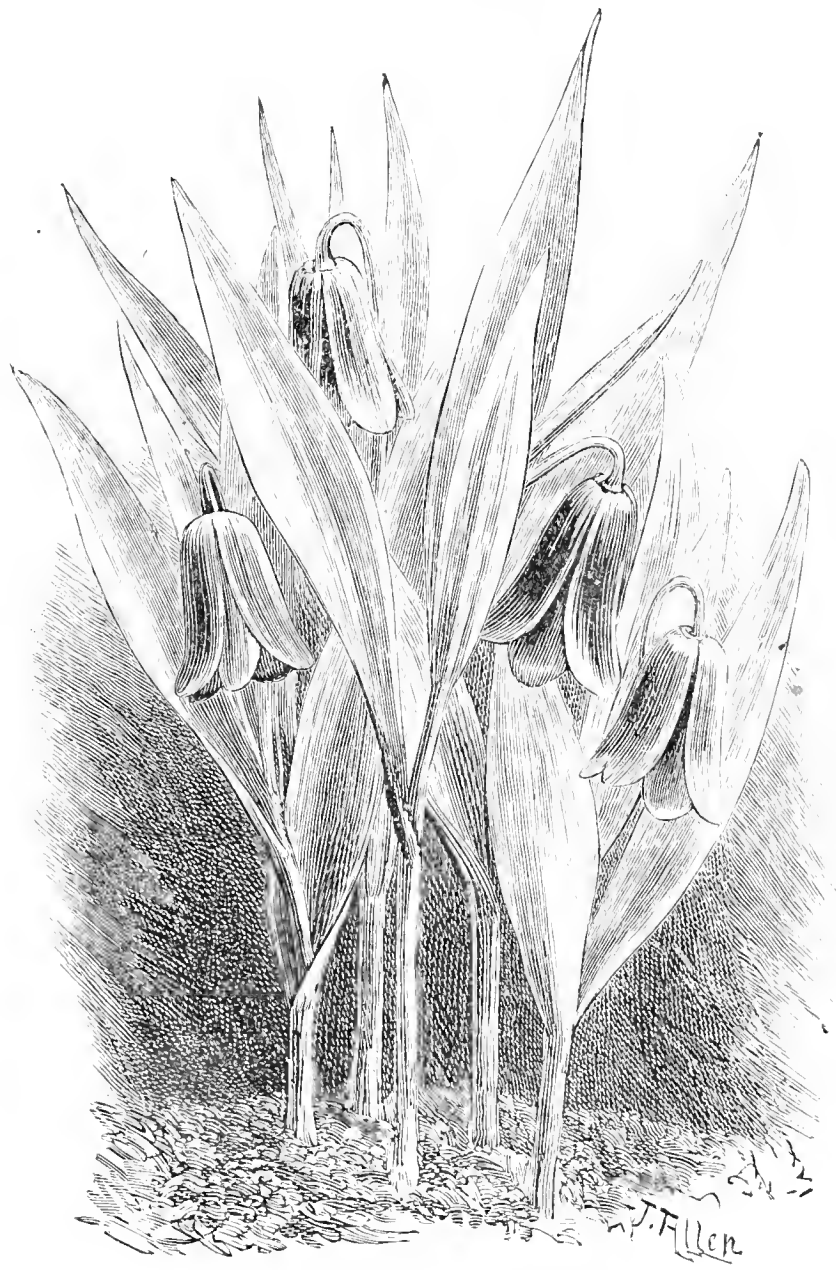

FIG. 13.—FRITILLARIA ARMENA.

know that the rootlets or fibres which are sent forth anew hy the parts above ground for the reception, aëration, and maturation of the sap when it is brought to them from below hy the system of circulation.—C. W. M.

(To be continued.)

ARISTOLOCHIA ELEGANS.

THIS desirable and beautiful tropical climber is seldom met with in a satisfactory condition; at least this is my experience, owing, I think, chiefly to its being confined in pots. Where I have found it to succeed the best is planting in front of the hot water pipes in a lofty stove. This Aristolochia was planted early in February of this year, in a mixture of three parts loam, and one each of peat and leaf soil, with a free amount of sand. The growths were trained perpendicularly until they reached the roof wires, which the plant now covers for the space of several yards.

This species is a free grower, the foliage heing of a rich grass green colour, and the flowers horne in great profusion on stalks 4 inches in length. The plant in question is hearing between 200 and 300 flowers and buds. The ground colour of the flowers is white, finely marked with veins of rich velvet chocolate. The shape of the flower is most curious, resembling a pipe, the howl of which has been turned back to meet the stem and then faced outwards.

One of the chief points to note in the management of this plant is to train the growths thinly, in exactly the same way as the Stephanotis is trained; in fact, the plant in question is growing side by side with a Stephanotis, both receiving similar treatment—viz., a free use of the syringe, and shade during the hottest part of the day.

The only insect which has made any attack on this Aristolochia is

a minute "red spider," and this only quite close to the hot water pipes. This comparative freedom from insect pests may be attributed to the peculiar smell which the foliage possesses.

The plant may be increased by means of seeds and cuttings, the former being sown as soon as ripe, the latter inserted as soon as procurable in small pots filled with sandy peat and loam, and kept in brisk heat.—YOUNGSTER.

CULTIVATION OF ORANGES.

ALTHOUGH Oranges are not grown for dessert purposes so much now as in former times, fruiting plants or trees are almost indispensable for winter decoration. Specimens may be obtained from cuttings of half-ripened wood, under a bell-glass, in a bottom heat of 75°, growing the plants well for two or three seasons.

During growth they must never be allowed to become dry at the roots, and frequent syringings are necessary to keep the foliage clean and healthy. Abundance of light, and a free circulation of air, are essential conditions for producing the sturdy growth and large glossy leaves which betoken good health. By judicious pruning, and stopping strong growths, trees 2 feet high, and brought into bloom in February or early March, will bear sufficient fruit to ripen, and help to make the conservatory attractive in the depth of winter. Tying and twisting the branches in, with the object of showing the fruit better, should be avoided as much as possible; allowing them to appear in natural freedom is decidedly more artistic.

Should mealy bug attack the plants petroleum and water sprayed on by a careful operator is an effectual method of dealing with it, or if red spider and thrips show themselves sponging with softsoap will eradicate the pests.—R. A. ANDERSON, *Alnwick.*

[Our correspondent will oblige by allowing fully twice the amount of space between the lines of his generally well-written communications.]

FRUIT FORCING.

Figs.—*Trees in Pots for Early Forcing.*—Red spider is the worst enemy of the Fig, barring scale, and must be subdued by forcible syringing at least once a day, in hot weather twice, directing the force of the water against the under side of the leaves, and if this is not sufficient an insecticide must be used, as it is important that the foliage be kept clean and perform its functions to the last. Scale does not yield to water, but requires treatment with an insecticide, than which there is nothing better than soluble petroleum. This is easily made by dissolving one part of softsoap in eight parts water by boiling, and then adding petroleum to any extent not greater than the extent of the dissolved soap and water, stirring well. For syringing use a wineglassful of the soluble petroleum to 3 gallons of water, and for applying with a brush to scale on wood that amount to 1 gallon. It is best to use hot water for mixing, and apply when cooled to 90° to 100°. Afford liquid manure to the roots, not to the extent of causing exuberance, but to insure a due supply of nourishment and the storing of assimilated matter in the wood. Pinching, with a view to induce a neat habit in young plants, with fruitfulness, must be attended to, regulating the stopping by the vigour of the plants and varieties. Strong growing sorts will need to be more closely pinched than those of moderate growth, but in all cases avoid overcrowding the shoots, for fruitfulness is not so much dependent on ample foliage as on a legitimate proportion duly exposed to light. The trees must not be huddled together, but each have space essential to the proper development of the tree under all the light possible, and free ventilation to solidify the growth as it is made. For early forcing the small varieties Early Violet and St. John's, with Pingo de Mel and Brown Turkey to follow, are suitable.

Second Crops.—Planted-out trees started about the new year will have the second crop in an advanced state, and must have a final thinning if not already effected, reserving those fruits near the base of the growths, which finish better than those near the points. Thinning is of vital importance, because fruit-bearing is an exhausting process, and the first crop having to be borne on the young growths of the preceding year, that part must not be enfeebled by carrying a heavy load of fruit. First crops are the most valuable. Any cultivator can grow second crops, and the chief cause of the failure of the first is imperfect ripening of the wood. Nor must the energies of the trees be taxed too severely by the second crop if they are intended to afford fruit early next season. Attend regularly to training and stopping the shoots, keeping the points well exposed to the light. Train thinly, tie loosely, and leave plenty of space in the ligatures for the shoots to swell. Stop side shoots at the fifth leaf, and rub off those not required, for spur growths to the extent of crowding are fatal to fruitfulness.

Afford water copiously through a light mulching of short lumpy manure, not any surpassing horse droppings duly sweetened. If used fresh and too abundantly there is danger of injury to the young growths. Such dressing admits air, and contains ammoniacal elements of great benefit to the trees. Liquid manure will be necessary according to the vigour of the trees and the extent of the rooting area. Trees in narrow borders may need it every day, others at longer intervals. They can hardly have too much water in hot weather, and they stone more in a week of fine weather than in a month of dull. The border, however, must be of sound material, and the roots active. Forcibly dislodge red spider by syringing twice a day, which, with proper feeding, will occasion little need of insecticides; but scale must be removed with a brush and a soapy solution. Admit a little air constantly, increase it early and close early, with plenty of atmospheric moisture, allowing the heat to rise to 90°, and the fruit will swell to a good size. Then a circulation of air constantly will enable the grower to produce Figs of the highest quality, which are wholesome, nutritious, and much appreciated at dessert.

Peaches and Nectarines.—*Early Forced Trees.*—Where trees are grown in pots of the very early varieties, such as Alexander, Early Beatrice, Early Louise, Hale's Early, Dr. Hogg, and Stirling Castle Peaches; Cardinal, Early Rivers, Advance, and Lord Napier Nectarines, they may be placed outdoors as soon as the wood has become firm, assigning them a sheltered sunny situation, keeping duly syringed and supplied with water. They will then not be liable to over-maturity of wood or buds, and buds will form on the laterals, which usually set freely. Planted-out trees started at or before the new year have been cleared of fruit, and the wood on which it was borne removed. This, and the taking out of any superfluous shoots, admit light and air, so that the wood retained becomes brown and hard, and the buds attain perfect formation, but this is contingent upon clean foliage and proper supplies of nutriment. The trees, therefore, must be syringed, and, if necessary, have an approved insecticide promptly applied, supplying water, and in the case of weakly trees liquid manure, to the roots so as to keep the soil healthfully moist. Mulching with light rather lumpy manure a couple of inches thick will keep the surface moist, the roots active, prevent the soil cracking, and assist in the retention of the foliage in health. The buds will be sufficiently advanced and the wood matured to allow the roof lights to be removed, and this should not be further delayed. This secures a sort of rest, has a most beneficial effect on the trees, while the soil becomes well moistened by the autumn rains.

Succession Houses.—The grand varieties Dymond, Royal George, Grosse Mignonne, Noblesse, Bellegarde, and Goshawk Peaches; Lord Napier, Stanwick Elruge, Dryden, Humboldt, and Pineapple Nectarines are now ripening on trees started in February, and leave very little to be desired in size, form, colour and quality. As the fruit is cleared off the trees, cut out the wood that has borne it, thinning the growths where they are so close that the foliage cannot have exposure to light and air. Cleanse the growth by means of the syringe or engine with water of dust and red spider or other insects, using an insecticide if necessary. Keep the borders moist, not soddened, affording liquid manure if the trees are weak, have borne heavily, and the buds are not developing well, but keep it from those inclined to over-luxuriance. Stop all laterals to one joint, but where the buds are in an advanced condition allow a little lateral extension, which prevents the premature ripening of the foliage by continuing the root action with at the same time growth on which to expend it without danger of starting the principal buds. When the buds are well formed, the fruit having been cleared off the trees, remove the roof lights. If under fixed roofs ventilate to the fullest possible extent.

Trees Swelling their Crops—Those started in March have stoned, and are taking the last swelling. Draw the leaves aside and raise the fruit by means of laths with its apex to the light. Water the inside border and outside if inclined to dryness, affording liquid manure and a mulch of lumpy manure. Avoid a close surface, for it excludes air, and that it be open is essential for the assimilation of food for taking up by the roots as its elaboration by healthy foliage. Ventilate early, in fact leave a little air on all night, syringing by 7 A.M., and through the early part of the day ventilate freely. When the sun loses power in the afternoon reduce the ventilation and raise the temperature to 85° to 90° about 4 P.M. with a good syringing and damping of surfaces, but it must be done with judgment, for when water hangs for any length of time on the fruit during the last swelling it is apt to damage the skin, causing it to crack, and imparting a musty flavour; therefore have the fruit dry before night, and if the day is dull omit the morning syringing. Directly the fruit commences ripening cease syringing, but afford air moisture by damping the paths, and especially the border, whenever it becomes dry, ventilating rather freely, and admit a little air throughout the night.

Late Houses.—If it is desired to accelerate the ripening ventilate rather freely in the early part of the day and up to the early part of the afternoon, then keep the heat obtained by reducing the ventilation so as to secure 80° to 85°, and at about 4 P.M. close, syringe well, and no harm will come if the temperature rises to 90° or 95°, ventilating a little at the apex about six o'clock so as to let the pent-up moisture escape and the temperature gradually cool down. Regulate and tie down the shoots as they advance, allowing no more than are necessary for next year's fruiting or for furnishing the trees. Let all have space for development, keeping laterals stopped to one leaf, and retain growths to attract the sap to the fruit. Any gross shoots pushing laterals from the leaf buds may be cut back to where the buds remain intact, or, if likely to disarrange the equilibrium of the trees, cut them out altogether. They only tend to promote gumming, imperfect setting, and certain casting of the fruit in stoning. Draw the leaves aside from the fruits, which raise from the under side of the trellis and expose to the sun. If the fruit is required retarded ventilate freely day and night; but do not, as a rule, have recourse to shading, though a slight shade obtained by drawing herring nets over the roof lights is beneficial than otherwise where the panes of glass are large. Observe the conditions laid down

in the preceding paragraph after the fruit commences ripening, also as to assisting the swelling.

Wall Cases.—Secure the growths to the trellis as they advance, being careful to allow space in the ties for the swelling of the shoots, neglect of this is a precursor of gumming. Keep the growths thin to allow of the foliage having full exposure to light and for development. Syringe about 7 A.M., the house having a little ventilation constantly, increasing this with the advancing temperature to 75°; or if it is desired to accelerate the ripening, maintain a temperature of 80° to 85° during the day, but always with ventilation, and close sufficiently early to maintain that temperature, but not to raise it above 90°. Syringe again about 5 P.M. Red spider will not make much headway, provided the syringing is thorough, and the trees are well supplied with water at the roots. Afford liquid manure to weak and heavily cropped trees. Thin finally directly the fruit is stoned. Neglect of early thinning results in thin-fleshed, flavourless fruits, and they sometimes ripen prematurely.

THE KITCHEN GARDEN.

Late Broccoli. — Attempting to grow extra fine late Broccoli frequently ends in failure. If the plants are grown luxuriantly they are liable to be destroyed by severe frosts, whereas sturdy, short-stemmed plants frequently produce valuable heads in the spring. Planting on firm, good ground, and not crowding the plants, are points to be observed in the cultivation of both midseason and late Broccoli, and no better site than a breadth of ground newly cleared of old Strawberry plants can be found. Draw moderately deep drills midway between the old lines of Strawberry plants, putting Broccoli plants 2 feet apart in the rows, and watering heavily. If midseason and late Broccoli have to be planted on ground recently dug make the latter firm, and also well ram the soil about the roots. Let the rows be from 30 inches to 3 feet apart, giving the greater distance if the soil is rich, and the plants from 2 feet to 30 inches asunder in the row.

Borecole, Chou de Burghley, and Savoys.—The first-named is most profitable when planted out on good firm ground somewhat early, but it is not yet too late to plant. Put out late they will not attain a great size, and may therefore be arranged 12 inches to 18 inches apart in rows 2 feet apart. Asparagus and Buda Kales are extremely hardy, and produce abundance of succulent shoots long after the other varieties are over. They may be planted thickly. Chou de Burghley, planted early on good ground, becomes coarse, also hearting in before it is wanted. Planted with late Broccoli it requires less room, a distance of 18 inches apart each way sufficing, and the hearts are neater, later, hardier, and much appreciated accordingly. Savoys may yet be planted on good ground. Allow the smaller varieties the same space ordinary Cabbages require.

Sowing Cabbage Seed.—July is the month in which seed should be sown with a view to having abundance of Cabbages next spring. In cold districts the second week in July is a good time to make the first sowing, on or about July 20th answers well in the Midlands, and the end of the month is early enough for the more favoured south. This season the ground is very warm, and when moistened prior to sowing the seed will germinate quickly. If the dry weather continues and broadcast sowing is resorted to, thoroughly soak the ground, sow the seed thinly, and cover with one-half inch of sifted dry soil. This plan is preferable to sowing in drills, especially if the plants are not pricked out previously to moving them into their winter quarters. The site cleared of spring-sown Onions is to be commended for early Cabbage, otherwise the ground to be planted must be well manured and deeply dug, so as to have it in readiness for the plants by the time these are fit to put out.

Parsley.—If seed is sown now in well moistened drills and covered with dry soil it will germinate quickly, and the plants, allowed sufficient room to develop, may probably prove hardier and more generally serviceable than those raised earlier in the season. Moderately strong plants transplant readily, and the check of removal prevents grossness and fits them for the winter. Select dull weather if possible for the operation, well soak the ground before raising the plants out of it, and save as much of the thick carrot-like root as can be done. Replant firmly in good ground, shade from strong sunshine and keep moist at the roots. Parsley is in such constant demand that every gardener will do well to take great pains in rearing abundance of it.

Winter Spinach.—Those who would be successful with this important crop must, as a rule, pay more than ordinary attention to the preparation of the ground devoted to it. The last week in July will be early enough to make a first sowing, and a distance of 15 inches apart will not be too close to arrange the rows of the superior large leaved varieties.

Watering and Mulching.—Where a heavy watering is given rows or beds of vegetables during very hot weather little trace is left of it twenty-four hours later, unless the ground is also mulched with strawy manure, old Mushroom bed manure, and the like. These mulchings are a great saving of labour, and of marked effect upon the crops they protect from drought at the roots. Apply them after a good soaking of water or liquid manure has been given, a dry covering, even of fine garden soil, having a better effect than a moist one. It is a mistake to think liquid manure of no service in hot weather. It is the poorer, hungrier soils that are the first exhausted of moisture, and a soaking of liquid manure is not taken out of the soil by the plants occupying it nearly so quickly as clear water would be. Once the watering of vegetables is commenced it must be persevered with, otherwise harm will result, the plants forming fresh root fibres only to lose them again. Driblets do more harm than good.

THE BEE-KEEPER.

The Swarming Mania.

Bees have had a perfect mania for swarming this season. Not in one district only, but throughout the country there has been an unusual number of swarms, and as is often the case they come off at a most inconvenient time. An extract from one of the numerous letters to hand from various parts of the country shows the difficulties that sometimes arise when swarms do not select the most convenient spot for alighting. "T.," writing from one of the midland counties, says, "I got very wild with my bees on Sunday. Just as I was going to church a fine swarm came out of one of my frame hives, but instead of clustering in one of the dwarf fruit trees, as they usually do, they clustered on the branch of a high tree, and after mounting a 42-rung ladder I successfully hived them. How is it bees so often swarm on a Sunday?"

The sudden changes in the weather are doubtless the cause of the swarming mania. When it has been dull for several days the bees are to a certain extent confined to their hive, this being followed by a few days of great heat. If the hives are not then well ventilated and the bees shaded swarming is almost certain to take place, as the bees will start queen cells, and when this has once taken place nothing will prevent them from swarming. It is then better to allow them to swarm, for if the new swarm is placed on sheets of fully drawn out combs, and a crate of sections placed on the top, they will at once store a surplus.

The original stock may then be used for queen rearing. This is a much better plan than cutting out all queen cells but one, as the bees will sometimes cluster round the entrance of hive and not work, although the weather may be favourable for doing so. It is very easy, too, in examining a strong colony, not to observe all the queen cells, and if more than one are left the bees will swarm again the first bright day that comes; and without attempting to answer the query, "Why bees so often choose a Sunday to swarm?" it may be that all is quiet in the apiary on that day, but it is usually connected with great and sudden heat, such as have occurred on several occasions this season. To-day (14th inst.) a shade thermometer registers 84°, and the sun shines brightly from a cloudless sky; perfect bee weather, but I fear too late for this district (South Yorkshire). Swarming is now all over, and those bee-keepers who still swear by the straw skep are looking forward to a good honey harvest owing to the great number of swarms they have had. May this prove as satisfactory as the swarming has been.

Stray Swarms.

In no previous season have I known or heard of as many stray swarms as this year. Where they have come from it is difficult to say. In some instances they have doubtless come from colonies that have made their home in trunks of hollow trees, or in the roof of some dwelling house, but more often they come from straw skeps that are kept by cottagers in various parts of the country. These are often left to chance, but are usually placed in a warm corner of the garden having a southern aspect. Swarms from stocks so situated often come off without being observed, and cluster not many yards from their stand, and if not at once hived will again get on the wing and fly a mile or more from their original stand, and are then lost. Great heat is often the cause of bees not settling. A correspondent in the West of England says, "An unusual number of swarms have flown away in this neighbourhood. I attribute the cause to the sudden heat, and have observed it before when similar weather prevailed."

In this district at least a dozen swarms have been seen flying over the tops of the trees, only in one instance were they taken. Some of the stray swarms would doubtless find a home in the hollow trees; others, again, would not be so fortunate, but would cluster unseen, and gradually dwindle away and die. This, I fear, is the end of many of the stray swarms, which, with good management in a hive, would have stored a surplus to the benefit of the bee-keeper as well as themselves. It cannot always be prevented, but in the majority of instances it may.

Swarms Deserting their Hives.

I do not know of anything more annoying to the bee-keeper than when he has carefully hived his bees, and placed them in a frame hive, to find on examining it the following morning that the bees have disappeared, and are nowhere to be seen. One such case has come under my notice this season. A cast from a straw skep was placed in a frame hive, half a dozen frames of fully drawn-out combs were given to them. These had been used last year for extracting purposes; since that time they had been stored

away, wrapped up in carbolic cloths. The combs had not been sweetened by exposing them to the air previous to being used on this occasion.

The cause of the bees deserting their hive was at once apparent—the combs still retaining a slight smell of carbolic, the bees absolutely refused to remain in the hive. Had the combs been sweet the bees would not have left them. In every instance that I have inquired into of bees leaving their hives, I have always found a cause for them doing so. If the interior of the hive is not sweet and clean, bees cannot be induced to remain in it. If disinfectants have been used on either frames or hive, they should be well exposed to the weather for a few days before being used, there will then be no difficulty in getting the bees to remain in their hives.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," *8, Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Canterbury Bells with Deformed Flowers (*Tilmah*).—The flowers are what is known as "blind," the corollas being suppressed. This is considered to arise from using old seed, which may in some cases have that effect more or less, but the anthers are affected by a fungus (Ustilago antherarum), which prevents the development of the corollas. There is no remedy but to pull up the plants and burn them, and in future secure seed from a fresh source. The spores of the fungus probably go over with the seeds, enter the plants by the roots, ascend the stem, and develop in the anthers in due course. This takes place without destroying the host plant, but completely spoils it for flowering. In some cases seeds are formed without the corollas, and with these the spores of the fungus are probably transmitted.

Rose Leaves Diseased (*A. W. H.*).—Badly infested are the leaves with Rose brand fungus (Coleosporium pingue). This is the perfect stage, which may be recognised as prevailing where the dark brown or black spots appear, the orange spots being the earlier condition, or uredo stage. Both occur together, the latter, however, first; but there are abundance of both on the leaves. A worse case we have not seen. The resting spores remain over the winter, giving rise to promycelia and spores, which push their germ-tubes into the tissues, producing abundance of orange coloured uredo spores in the spring. Dust the plants forthwith with a powder containing 10 per cent. of sulphate of copper, such as in the fungicides advertised—viz., fostite, anti-fungi, or anti-blight, using a bellows apparatus so as to coat the leaves on the under side; or spray with Bordeaux mixture, taking care to reach every part of the plants. If you do not care to use a poisonous preparation obtain permanganate of potash from a chemist, mix 1 oz. in 3 gallons of water, and apply with a fine rose syringe, or, better, with a spraying apparatus, as being more economical and effective. Remove fallen leaves and burn them. In winter use sulphate of iron ¼ oz. per square yard and 7 lbs. of basic slag phosphate with 1¾ lb. of kainit per square rod, digging in after the leaves are down. When the plants are quite dormant dress them by means of a brush with a solution of bluestone (sulphate of copper), 1 oz. to 1½ gallon of water. Early in spring supply 4 ozs. per square yard of the following mixture:—Dissolved bones five parts, nitrate of potash three parts, and sulphate of lime four parts, mixed, pointing in lightly. Keep a sharp look out for the appearance of minute yellow spots on the leaves, or, preferably, before they appear dust the plants with a fungicide or spray with permanganate of potash, dissolving 1½ oz. softsoap in each gallon of the water. This causes better adherence to the foliage. Apply when the first leaves are about full-sized, and repeat every fortnight or three weeks up to the middle of June.

Propagating Pomegranate (*J. T. S.*).—Plants may be increased by cuttings of shoots when becoming firm at the base, keeping them rather close and shaded until rooted. Some persons prefer inserting cuttings of ripe wood towards the end of summer in sandy soil. Layering is a sure method of increase, this being done in pots, notching the growths where they are to be inserted in the soil, and making each secure with a peg. The pot can be raised by means of sticks to the required height. Scarce varieties are increased by grafting on stocks of the common kind, which are raised from seed, usually taken from imported fruit, and sown in sandy soil in gentle heat early in the spring. The plants are ready for grafting when of the thickness of the scion, operating by whip-grafting before the grafts commence growing, but the stocks in activity.

Duke of Buccleuch Grapes Splitting (*W. T.*).—The chief cause of the berries cracking is excessive moisture (for the variety) in the atmosphere, with too liberal supplies of nourishment at the critical period of ripening. There is no preventive other than allowing as good a spread of foliage under such circumstances as can well be afforded, keeping rather dry at the roots and affording a plentiful amount of air, some constantly. Cutting through the shoot about half way affords some relief, but not always enough; therefore more air, so as to induce constant evaporation, is the most effectual. Of course, this is difficult of attainment with other varieties in the house; but even the extra ventilation will not materially prejudice the others, but the border cannot well be kept much drier on their account. You may notch the shoots below the bunches still more, but not so far as to prejudicially affect the leaves, or not more than to make them a little limp; but air with a drier atmosphere is the best preventive of the evil in question.

Peaches Hollow and Decayed (*H. S. W.*).—The large and fine fruits were, as you say, "hollow and decayed at the stone." It is a very serious matter to have such grand fruit go wrong on a six-years-old tree, not a few here and there, but "all the same last year and this." We are sorry to see such a result accrue from the assiduous attention you have given, and sympathise with you on the misfortune. The fruit are what is known as "split at the stone." The cause has been attributed to imperfect fertilisation, but in your case the part of the kernel inside the integument was perfect in embryo. The splitting of the stone in this case arises from excessive development, the available mineral elements not being in due proportion with the nitrogenic. Some varieties, however, are more subject to it than others. We have found lifting a complete preventive, the work being done carefully in the autumn as soon as the leaves give indications of falling, and after lifting applying a dressing of basic slag phosphate, two parts; and double sulphate of potash and magnesia, one part; mixed, using 4 ozs. of the mixture per square yard, and pointing in with a fork without material prejudice to the roots. In the spring, when the trees commence growing, supply a mixture of dissolved raw bones, dry and crumbling, three parts; and muriate of potash, one part; mixed, using 4 ozs. per square yard, covering with a light mulching of decayed lumpy manure, not more than an inch thick. This, with the usual cultural treatment, gave us complete immunity from "splitting at the stone." The advertised fertilisers would answer quite as well, but lifting is the most needful operation, and if the soil be deficient in lime add some old mortar rubbish, broken up fine, to the soil as the work proceeds.

Malmaison Carnation Plants Dying (*F. C.*).—The plant in the 24-size pot was completely decayed and dead at the stem where in contact with the soil, and in the decayed substance were root stem eelworm (Tylenchus obtusus). This was the cause of the stem decaying, and the "grass" simply collapsed in consequence of the supplies of nutriment being cut off, but gradually, so that the foliage first became pale and spotted here and there and withered on the plant from the base upwards. The spots closely resemble those due to the fairy-ring spot fungus (Heterosporium echinulatum), which was discovered and described by the late Rev. M. J. Berkeley twenty-five years ago, but there are neither hyphæ in the tissues nor outgrowths, and the eelworms are confined to the root stem. Even the plant with an apparently sound root stem has the spots, and the stem tissues in the ground are affected with the eelworm. The cutting or small plant had entirely succumbed at the base—its trusses decayed and eelworm in them. It is the species named, not the ordinary stem eelworm (Tylenchus devastatrix); but this also attacks Carnations. The soil is too open and fibrous for these plants. We should add to it at least 2½ per cent. of best chalk lime, air-slaked, or only using sufficient water in slaking to cause the freshly burned lime to fall to a fine powder, mixing it with the soil, and allowing this to lie for a few weeks before using. For direct application to the plants, sprinkle about half of a small teaspoonful of common salt on the soil of a 24-size pot, and water so that the water shows at the drainage. The next time the plants need water, use a similar amount of basic slag phosphate per pot, and wash in as with the salt. When the plants require water again, use a similar amount of this mixture: sulphate of potash, three parts; dissolved bones, dry and crumbling, two parts; sulphate of ammonia, one part; mixed, washing in as before. The plants may look rather sickly for a time after the application, but they usually recover when not too seriously infested. If you can obtain soluble phenyle, mix at the rate of a quarter pint to three gallons of water, and apply before the salt and other ingredients are used. In that case you may use all three substances mixed together—that is, one part salt, one part basic slag phosphate, and one part of the mixture of sulphate of potash, dissolved bones, and sulphate of ammonia, employing a thimbleful at intervals of a fortnight or three weeks to a plant in a 24-sized pot. Burn the worst of the plants, and use less vegetable matter in the soil.

Plum Trees Diseased (*W. S.*).—Your question cannot be properly answered this week. The subject shall have attention in an early issue.

Sowing Grass Seeds (*Kittie*).—The state of the weather and condition of the soil are matters of more importance than any mere date in the calendar for sowing lawn or grass seeds. You may sow on the north aspect as soon as the ground is in a thoroughly moist state. Excellent lawns have been formed by sowing in August and early September, and it is better to sow in the last named month when the ground is moist than earlier when it is dry. We should not let a favourable opportunity pass in August if we intended to sow. It is advantageous to have a sufficient growth of grass to be "switched over" with a very sharp scythe in the autumn.

Exhibiting White Grapes (*Vitis*).—In the judging code of the Royal Horticultural Society, Tynningham, Bowood, and Charlwood Muscats are for purposes of exhibiting regarded as synonymous with Muscat of Alexandria. Canon Hall Muscat is not so considered and specified; therefore if the show to which you refer is to be judged in accordance with the R.H.S. rules, an exhibit including Muscat of Alexandria and the true Canon Hall Muscat in such a class as you mention would not be open to disqualification; but if the adjudications are not to be under these rules, there is no telling what view the judges might take, and if their decision is announced to be "final," and the exhibit were disqualified, they would be masters of the position. You must now exercise your own discretion in the matter. If all exhibitions were to be judged in accordance with the R.H.S. code, no one would be in the least prejudiced, while both exhibitors and judges would know exactly what to do in such cases of doubt as this.

Stopping Peach and Nectarine Trees in Pots (*Lampeter*).—The shoots should have the points pinched off when from 6 to 10 inches in length. This refers to the leading shoots of the trees, and where desired to originate others for furnishing them with branches, it not being advisable to have them very closely together, but so far apart that the hand can be passed between them without disturbing the leaves. This will allow light to reach the foliage at the base of the branches, and they will form firm growths on which the fruiting depends. Side shoots on the branches, and where not required for extension, should be pinched to two or three leaves to form spurs, and the laterals from these and elsewhere may be pinched to one leaf as made. Extension growths once pinched will push again, and when the leading lateral has made about three leaves stop it, when probably not more attention in these respects will be required for the season. Keeping the growths carefully stopped and fairly thin is a point of some consequence in order to secure a fairly symmetrical habit, as well as for insuring fruitfulness.

Madresfield Court Grapes (*W. H. T.*).—We think you have rather overcropped the Vines for securing the best colour in the Grapes. Moreover, this variety does not colour so quickly as some others, and the fruit may yet finish better than you imagine. You may perhaps be surprised to hear that the fine berries you sent have perceptibly deepened in colour since we received them. Beyond giving another application of the farmyard liquid, if the border is in the right condition to receive it, we do not see what can be done in addition to the excellent routine treatment described in your letter. We have known more than one instance of the border being kept fully too dry during the colouring stage of this fine Grape from a fear of the berries cracking, but they are much more liable to split when the border is too dry and the atmosphere too close and moist than they are under reverse conditions. Of course it would be foolish to give either water or liquid manure if the border is already moist enough right through for the well-being of the Vines. Please say whether there has been any improvement in the Grapes since you wrote more than a week ago; also say whether the other black Grapes in the house colour well as a rule or not, and the subject shall have further attention. If your letter had not been accidentally misdirected it would have been just in time for being answered last week.

Pruning Young Orchard Trees (*L. Morris*).—You planted a young orchard in March and was advised not to prune, and so the long young branches were left intact. The leaves have fallen from the branches of some of the trees except tufts at the ends, and there is an attempt at premature fruiting. You now ask "if you should cut back freely or whether the trees may be left to recover another year?" Cut all the trees back freely, but not now. October will be soon enough. If you leave them unshortened another year some, if not all, will be practically ruined, as hundreds have been by want of assistance. In all probability, if two-thirds of the length of the branches had been cut off when the buds commenced swelling in the spring the trees would be in a much healthier condition than they are now. However, as they are alive, and you shorten them as suggested in the autumn, you may not lose much in the end, as they may be expected to make good growth next year—much better than can possibly be produced if left as they are. When the trees were dug up more than two-thirds of the fibrous roots which had been necessary to produce and support the branches were left behind in the soil. With more than two-thirds of the root power lost, how do you think the unshortened branches could be supported and free extension growths produced by them? The extent of the shortening depends somewhat on the length and number of the young branches. If you like to send particulars on those points we will willingly refer to the subject again. Elementary questions are often the most important of all. We suspect you are more likely to err in not shortening the branches enough than shortening them overmuch.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*R. B.*).—1, Campanula latifolia; 3, C. pumila; 4, C. pumila alba. There was no specimen in the box numbered 2. (*C. D. F.*).—1, Inula glandulosa; 2, Olearia Haasti; 3, Viburnum lantanoides; 4, Polemonium cœruleum variegatum. (*F. V. C. O.*).—1, Bocconia cordata; 2, Verbascum Chaixi; 3, Antennaria tomentosum; 4, Spiræa Billardi; 5, Œnothera Lamarckiana; 6, Thalictrum aquilegifolium.

EXTREMES MEET.

Yes, that indeed they have during this past month of June—a month that has been anxiously expected, a month that will ever be remembered wherever the Englishman is found, or the English tongue spoken. Early in the year the prophets were busily at

work, and had we been superstitious our minds would have been filled with dire foreboding. Queen's weather we prayed for, "Cold and rain, a season like the miserable one of 1861," was the prophets' cry. We are so dependent here on sunshine. Moisture is usually superabundant (we speak advisedly), the drougbty summers in the Midlands north are rather tbe exception than the rule. A really wet season, that is wet with cold, is disastrous. The summer is too short as it is, that we want every bit of bright weather that we can get.

Well, June has come and gone, and like fickle April or Mrs. Gummedge, has been most "contrairy;" and taking her as a whole she has done us good, and not ill. May went out with balmy breezes and fair skies, and June came in with every promise of blessing. The late showers of May had caused the grass to spring with great rapidity, work was forward, and tbe farmer had bis hands more than full. The farm notes from all the country side for tbe first week in June note tbis delightful state of things—beneficent sbowers, warm sunshine, pastures carrying any amount of stock, and the aspect of the cornfields cbanged in twenty-four hours. Till then it had been feared that the keeping for the summer would be scarce, and the hay crops meagre. As stack yards were empty, and hay and fodder nil, the prospect was gloomy. We do not doubt that possibly in some of the more southernly counties the hay crop may yet be below the average, but taking the country as a whole the crop is excellent; and this year of Jubilee there may be hay, and to spare—winter keep seems assured.

Whit-Sunday found us sweltering; brilliant sunsbine, with little or no breeze, the ground felt warm under the tread, and the day generally was spent as a period of rest. By Monday morning there was an indefinable something in the air; a change seemed imminent, and come it did; and that quickly. We were all shrugging our sboulders till one, braver than the rest, suggested a fire. No sooner said than done; but wbat about the poor stock in the fields? "Cold as Cbristmas" was our verdict, and Tuesday worse, with leaden skies and a sullen downpour, that only resolved itself into a drizzle as the day spent. Then came cold drying winds, to be followed only by blazing suns and the regulation thunderstorm. Why cannot we have good things in moderation? From the 13th to 19th stormy winds, and such winds! making the gardens a very wilderness, and dashing and thrashing all delicate foliage till the country appeared as though it had suffered from a blast of shrivelling flame. The rain was plentiful, and this and the storm generally seem to have been confined to the more northerly provinces.

This is how one north country farmer speaks of tbe gale of June 16th. "The storm of wind on June 16th was such as the oldest inhabitant cannot remember in that month, which tossed and knocked our crops about most disastrously." Tbis is from Lancashire. On the same date—*i.e.*, June 16th, we read, "Wigtonshire: A flood, followed by a hurricane of wind; branches were broken off trees, fruit trees fairly blanched and spoiled, vegetables almost blown out by tbe roots, Potatoes blackened in the leaves, and singled Turnips fairly blown away. On the 19th yet another flood." Trinity Sunday opened very doubtfully, and although little or no rain fell, there was every appearance of it, to be followed by a close, dank Monday, when the earth steamed. Then came forth old Sol in his glory. His Majesty to greet Her Majesty, and right royally did he do it, closing in with soft mists that made the night redolent of cboice odours. Wednesday was almost unbearably hot; but on Thursday we shut the windows and remarked tbat the house was comfortable.

Monday, 28th, down came the rain in sheets, and the air was warm and moist as a stove house; and pleasant sunsbine closed this extraordinary month—well, we wanted a record month, and we have got it. At one time there appeared every prospect that the great Royal Show at Manchester would be in difficulties owing to the storm of the 16th January—the bavoc it made among the wooden shedding and the galvanised roofs. But it would take more than a storm at the eleventb hour to disconcert the executive of the Royal, and tbe morning of 23rd found all spick and span. The management of that show is now brought to such perfection that only those who cavil for the love of cavilling can find anything to disagree about.

We have still another record of this month—such a sad one that we hesitate to add it to our cheerful pages, but no account of June, 1897, would be complete without a reference to the disaster which overtook the county of Essex on June 24tb, Midsummer Day. On that day the heat was excessive in London and Essex, and the thermometer registered 90° in the sbade. Only once has this occurred during the last nine summers. Then broke a thunderstorm unparalleled in our annals. At first we failed to grasp the magnitude of the disaster, but figures are awkward things to deal with, and when we hear the Lord Mayor of London has opened a fund for tbe relief of the distress in Essex, we want full particulars. Here they are. The area affected is stated to be from seventy to 100 square miles, from Epping to Abridge, to Burnham and Clacton. The money value of the damage is estimated at £200,000. All tbis destruction was wrought in twenty minutes! Hailstones of abnormal size, slabs of ice 4 or 5 inches long, 3 inches wide and 2 thick. Elms, Oaks, and Ash trees uprooted, those still standing fairly stripped of leaves, fields of Wbeat where not one ear has escaped, Peas and other crops mangled and dying—the market garden industry, with the necessary greenhouses wrecked, destruction everywhere, and ruin staring the poor occupier in the face. All the work of the winter and spring undone, and in only twenty minutes! Mr. Long has been down himself to the scene of the disaster, and has also instructed an inspector to prepare a full report of the damage. Whether Government will do anytbing in the shape of a relief grant we do not know. To the benevolent an appeal will not be made in vain, and if we could find our millions for our stricken brethren in India surely we can find our thousands for the poor striving farmers of the Essex class.

WORK ON THE HOME FARM.

The weather is simply magnificent, and the Clover and hay are being stacked in splendid condition; many years should we have to carry back our memories or our diaries to find such a fine crop of well-harvested fodder.

Never did fine weather make an appearance at a more acceptable time; it has been simply splendid for killing weeds amongst the Turnips, and the heat has been also beneficial to the young plants, for young Turnips love warmth. Great complaints are rife of the damage done by roots to the plants after singling, in some cases one-half having been uprooted by the birds in search of wireworms. If the rook never pulled up a plant unless it were infested with wireworm, little blame would attach to him; but, unfortunately, the younger birds are not sufficiently discriminating, that is, are not educated highly enough to make no error in selecting only the infested plants.

Grain crops look well, and we can detect in the earlier fields signs of changing colour. With a continuance of bright sunshine, harvest should commence very early in August. That the grain is swelling fast is shown by the attention paid to it by the sparrows.

Maybe some farmers are wishing for rain, but except on very weak dry lands they would be better without it. There is an abundance of keep for the stock, and as roast meat is better than boiled for nearly all animals, rain might do much harm to their well-being, without materially increasing the bulk of their fodder supply.

Flock masters are about weaning the lambs. The best plan is to take the ewes away, leaving the lambs in their old pasture. The ewes should be put on short commons for a few days, and water must be carefully avoided. It is a good plan to place the ewes in a foldyard or similar place for twenty-four hours after the lambs have been weaned.

We were a few days ago very much interested in the very great contrast presented by two crops of Wheat in adjoining fields, one being apparently three times as heavy as the other just over the hedge. The land is naturally of a light nature. On inquiring the reason from the owner, we were informed that the field producing the poor crop had been heavily clayed at the rate of 140 tons per acre four or five years ago, and that it had never had a good crop on it since, but was hoping for better results in the future.

HARDY FLOWERS.

AS is the life of men and women, so is the life of the flowers. We come upon the world's stage, bear our share of the sunshine and storm of our time, and pass away. So, too, come the flowers. They have their trials and their joys. They are hurt by the storm; they revive in the sunshine, and fulfil their part until the winter carries them from our view. But a few days ago the garden was enveloped in driving rain and invaded by the remorseless gales which, rude as a horde of invading barbarians of old, wrecked and ruined all they touched. To-day it is flooded with sunshine, and the taller flowers scarce move to the gentle motion of the air. The change is great. Welcome is it to the gardener, and welcome seems it to the flowers, though they still bear traces of their recent trials.

That white Rose on the wall—a picture of beauty little more than a week ago—has not been spared. The flowers, once pure as the winter's snows, but full of warmth and grace, were disfigured by wind and rain, and were no longer forms of chastest beauty. That mass of white Pinks, once so delicious in odour and so pleasing in form, has become a heap of sodden, shapeless, scentless lumps. The Rose has begun to recover, and ere winter comes will give us many a welcome flower, but the Pinks have gone from our view for the year.

The great Delphiniums, with their spikes of blues and purples, have suffered too, and attest the fierceness of the trials they have undergone in their struggles with the storm. Others tell the tale; but it is an unwelcome one on a day such as this on which these words are written. It is one in which to rejoice and not to mourn, one in which we can drink to the full the cup of enjoyment prepared for the lover of gardens and flowers.

Looking through the garden after one of those seasons of storm and rain, we may pick up here and there some lessons to be turned to account again. One of these is the value of the single Pinks in bad weather. While the

exquisite double-flowered varieties—so redolent of sweet odours—have been defaced beyond repair, some of their single-flowered sisters are again covered with bloom, so little have they suffered from the rain.

There is one on a rockery which is admired by most people who see it, although, fine as it is, I think it a little formal in its way. It is an Irish-raised seedling, and probably from one of the old laced Pinks. I believed it is named Beauty. The flowers are large, being fully 1½ inch across, and the colour is of the purest white, with a broad, very dark chocolate-coloured zone, which contrasts well with the white ground and the good-sized white eye. It also holds its flowers well up, and does not let them hang down as do so many of the double forms. The edges are prettily fringed, and although, as I have said, a little too formal to be perfect, it is a pretty and attractive flower. There is a good deal of variety to be obtained in the way of seedling Pinks, and some beds of these seedlings I have seen contained excellent flowers worthy of distinctive names.

Very pretty, too, are some hybrid Pinks, among them seedlings from seed kindly given me by the Rev. C. Wolley-Dod. Dianthus superbus is unmistakeably present in the appearance of some of these, the deeply fringed and laciniated petals showing its influence.

The mention of hybrids makes one think it an appropriate time to again refer to Mr. Carrington Ley's hybrid Poppy, mentioned on page 19. This is to endeavour to make, as far as possible, the *amende honorable* for questioning the hybrid origin of this Poppy. It was, perhaps, as well that the saving clause that it might "arise from my own slowness of observation that I saw no conclusive evidence of hybrid origin" appeared, as I fear my observation was at fault. A letter from the kind donor of the plant, in reply to one of mine, led me to examine it once more, although for the time out of bloom. The result has been that I find that the form of the seed capsule and its colour present evidence of the relationship of the plant to Papaver rupifragum; while the flowers, as said on page 19, are those of a small P. bracteatum. There thus seems satisfactory proof of the hybrid origin of this Poppy, and it is a duty to correct any possible misapprehension to which former remarks might have given rise.

A seldom seen and rather singular looking flower has been in bloom for some time, and has attracted a good deal of notice from the garden visitors. This is one of the Sisyrinchiums, a genus belonging to the natural order of Irideæ. The best known of the genus is S. grandiflorum, a pretty spring-flowering purple species, of which there is also a white variety. S. angustifolium, often known as S. anceps, the "Blue-eyed Grass" of North America, is also occasionally seen in gardens. The one under notice—S. striatum—is, however, not often met with, and only came to me last year, and forms a pleasant reminder of a delightful garden in the Emerald Isle, where a happy time was spent.

Sisyrinchium striatum before it comes into flower looks exactly like a Flag Iris, with its broad glaucous green leaves and upright habit. From among these are produced the stems, which, including the panicles of clusters of flowers, are about 3 feet long. The spike or panicle of blooms is composed of several circles of small pale yellow flowers, with faint brown veins. At the outer edge the flowers are almost creamy white, deepening gradually to bright yellow at the base. These flowers are stemless, and are rather more than three-quarters of an inch across. They only open in the sun, and then the plant is very distinct with its cluster or whorls of flowers. As may be supposed from this habit a sunny position should be given, and a rather dry soil in winter will prevent the loss of a plant worth growing from its appearance. It comes from Chili and the Andes of Mendoza, and is propagated by seeds or division.

Although not showy Sisyrinchium striatum, which, by the way, has several synonyms, will attract notice amid the glow and colour which fills the garden now. Roses, Delphiniums, Pinks, exquisite Carnations, Poppies, Potentillas, Sedums, Sempervivums, Agrostemmas, Peas, Anthemises, Irises, Campanulas, Mulleins vie with the brightness of the earlier Lilies in bloom as we look out upon their glowing colours. The chaste Lily of the Madonna, L. candidum, is ready to open, when it will find rivals in the Water Lilies, which, now that summer has really come, look out from the water of the garden pool. Though the storm has left its marks still upon many flowers, there is left joy enough, beauty enough in what remain. The horn of plenty is full, well nigh to overflowing.—S. Arnott.

STRAWBERRY CULTURE.

(*Continued from p.* 69.)

General Management.

Shortly after the fruit has been gathered, and when the requisite number of young plants have been obtained from the beds, the latter should have a thorough overhauling. All runners and decayed leaves must be cut away, weeds and the rougher portions of straw removed, so as to leave the beds tidy till the autumn. The only attention then required till October will be to give an occasional hoeing to keep down weeds while they are in a young state.

As early as convenient in October the surface of the soil ought to be slightly broken up with a fork, and a 3-inch layer of half-decayed manure placed over it, covering the whole of the ground both between the rows and around the plants. This practice of autumn mulching is not only valuable from a manurial point of view, but also gives just the protection needed during severe winters. When the beds are situated on poor soils the plants derive immense benefit from the application of liquid manure during winter and early spring. Cesspools are often emptied at those times, and so powerful a fertiliser should never be wasted, for it is a "gold-finder" if applied to fruit gardens and orchards at any time except when the fruit is ripening.

Strawing the Beds.

This simple operation is performed at various times and in many different ways by gardeners and market growers. The latter frequently mulch with rather rough manure in the autumn, this becomes washed by the winter rains, and in spring is perfectly sweet and serves for the fruit to rest upon; but all things considered, I prefer to straw the beds in spring. The plan followed by Mr. Owen Thomas in the Royal Gardens seems to be a perfect one, which if more generally adopted would often prevent the prospect of a good crop being ruined by the occurrence of a sharp frost at blossoming time. Mr. Thomas piles the straw loosely between the rows just before the flowers open, they are thus to a certain extent constantly protected, and when danger from a severe frost is apprehended, the material already at hand can be quickly scattered over the plants, and when the fruit is set it only needs pressing around them

If the weather happen to be very dry when the fruit is swelling, one or two thorough waterings should, if possible, be given, as the performance or omission of this practice often accounts for the difference between a poor and a fine crop of fruit. Old plants become distressed through drought much sooner than young ones, and in some instances the young fruits wither and die; a state of affairs puzzling to not a few.

Varieties.

Laxton's No. 1 is generally considered the earliest Strawberry in cultivation, and being a good cropper, it is a valuable variety worthy of the attention of all. Its one weak point is that the flavour is not quite first-rate. Early Laxton is now being offered by the noted firm whose name it bears, who state it to be still earlier than the variety just named. A few plants of this should certainly be secured, as none of us can afford to neglect any improvement in this direction. Sir Trevor (raised at Windsor) is also slightly earlier than Laxton's No. 1, and should, therefore, when possible, be obtained for trial. Next in point of earliness comes Noble, which is really a grand Strawberry, notwithstanding its deficiency in flavour when grown on some soils. In light land it crops well, is very early, and the flavour is fair. In the markets it is certainly a fruit that "takes." Royal Sovereign is only a few days later than Noble, and in every respect a grand variety, the quality in this case being of the best. King of the Earlies is a wonderful cropper, but the fruit is small. The older variety, Vicomtesse de Thury, though a little later than the foregoing, is a good cropper, the flavour also being excellent. Laxton's Monarch is, perhaps, the finest second early in existence, being of enormous size,

wedge-shaped, and of a Queen-like flavour. The plant is of a compact habit of growth, and the foliage thick and leathery. If only one variety can be grown, let it be Monarch. Scarlet Queen is bright, handsome, and rich flavoured, and on that account should be grown as a second early.

Veitch's Perfection may, I think, be truly described as an improved British Queen. It is the result of a cross between that well-known variety and Waterloo, and seems to retain the good qualities of both parents. Among midseason varieties no better one can be found than Leader ; each year it gains in favour, and I think will in the future be as widely popular as Sir Joseph Paxton has been. The latter good old variety is still largely grown for market purposes. On heavy soils it is extremely prolific, and its handsome fruit always takes the eye ; the flavour also is very good.

Sensation will, I fancy, supersede President, which variety it greatly resembles, but is much larger. Laxton's Mentmore, sent out for the first time this season, promises to be a good thing. It is handsome in appearance, and, unlike most Strawberries of recent introduction, has a smooth external skin, carrying an attractive polish.

It is rather surprising that Auguste Nicaise is not more generally grown, producing as it does fruit of enormous size. I have seen grand crops of it at Wilton in Wiltshire, where Mr. Challis, Lord Pembroke's able gardener, grows it splendidly. A. F. Barron, Bothwell Bank, and Kitley's Goliath are also good main crop varieties.

Rich Flavoured Varieties.

There can, I think, be no doubt that the great size obtained in Strawberries of recent introduction has been obtained slightly at the expense of flavour ; I, therefore, give the names of a few of the best flavoured ones : Dr. Hogg, suitable for heavy soil ; Empress of India, Gunton Park, Latest of All, and Dr. Roden's Countess ; the last named is both large and handsome, and in every way a fine variety.

Late Varieties.

The season may be greatly prolonged by planting these under a north wall or in some other cool position. As a market speculation such a practice on a large scale would, I think, prove remunerative, and in private gardens late Strawberries are always highly prized. The best sorts to plant for the purpose are Frogmore Pine, Lord Suffield, Latest of All, and Waterloo.—Pomona.

PROPAGATION OF CONIFERS AND SHRUBS.

It is not often that gardeners in private establishments undertake the increase of trees, shrubs, and Conifers, but the propagation of many kinds by means of cuttings is easy, as they can be readily rooted and quickly grown into neat little bushes. A cold frame is all the protection required in the way of glass, but it is better if two smaller ones can be appropriated instead of one of the same size as the two, for the reason that some sorts require a longer time to root than others. Those that need more time can have the protection of the extra frame, while if the plants are kept together at the time of insertion the early rooted plants can be transferred to other positions some months before the latest varieties. The size of the frame must be regulated by the requirements of the cultivator.

A shallow frame answers the best, for the reason that when new growth commences it is not drawn up weakly through being so far from the glass. The bottom of the frame should be covered with coal ashes, thorough drainage being essential. Over this have a layer 2 inches thick of decomposed horse manure or half-decayed leaves, into which the roots penetrate, as the soil clings better to the roots when manure or leaf soil in a rough state is present. Over this lay the soil 3 inches thick, which should be composed of equal parts loam, peat, leaf soil, and sharp silver sand. Many of the plants which are to go into the soil are really peat-loving, therefore it is necessary that peat be used ; while some of the kinds would do equally well without, still none objects to this mixture. Make the soil quite firm, that it be not of a spongy nature, as much depends upon the firm manner in which the cuttings are inserted. If the soil be moist, as it should be when used, no difficulty will be experienced. Over the soil place half an inch thickness of coarse silver sand, as when the holes are made for the cuttings some of the sand is carried down to the bottom of the hole with the dibbler. Water the soil with a fine-rose waterpot, when all will be ready for the cuttings. This preparation should be made before the cuttings are obtained, as no delay in inserting them must occur after they are severed from the parent plants.

According to my experience the best time to take the cuttings is during the early part of September, when the current season's growth will be partly ripened, sufficiently so to make callusing an easier matter than if the insertion of the cuttings be delayed until the following month. Where it is possible the cuttings should be pulled or slipped off, retaining a small portion of older wood, which is more suitable for forming roots than the parts only of the current year's growth. Particularly does this apply to Conifers. The length of the cuttings must be determined by the plant under consideration, as, for instance, Retinospora plumosa may be 2 inches long, and Thuiopsis will need to be at least 4 inches long to obtain the necessary cut at the base containing a small portion of firm wood. Select the cuttings in the manner described, cut square across below a joint, trimming off the lower branches or feather as far as is required for the cutting to go into the soil. Fix them firmly at the bottom of the hole with the dibbler. Fill the holes again with sand and give a gentle watering to settle the soil about the cuttings. Unless the sun be very powerful after this time no more water will be required until the spring beyond a light sprinkling should the surface become dry, which will depend upon the state of the weather. For a time shade the cuttings during the hottest part of the day. Ventilation will not be required except a little now and then to evaporate moisture, which will otherwise cause the cuttings to suffer. During the winter protect the sides of the frame with manure or leaves to prevent the soil in the frame being frozen too hard, as this has the effect of loosening the soil about the cuttings when it thaws, and then roots are not so quickly formed. Double mats thrown over the frame in severe weather will be beneficial in this respect.

In the spring, when it is seen that new growth is being formed, air should be admitted freely to keep the plants stocky, as much depends on this for their future welfare in forming shapely bushes. A western aspect for the frame answers well, perhaps better than a southern position, for the reason that if some of the cuttings do not root so readily as others, the powerful sun sometimes experienced during April and May will dry them too much. As before stated, some kinds root more quickly than others, and are ready to be removed from the frame during the early part of the following June, and be planted either in their permanent quarters or be transferred to a nursery bed for a season. When removal from the frame takes place the advantage of a layer of manure or leaf soil will be seen in the manner the roots cling to it, rendering the process much easier and safer to the plants. The position for the plants the first year may either be on an east or west border, or any open space may be selected, planting either in nursery beds or in rows 9 inches apart, adding to each a portion of leaf soil if the natural soil be of a heavy nature, otherwise the addition of leaf soil will not be necessary. Should the summer be hot a mulching of partly decayed leaves between the rows will be of great advantage in keeping the roots cool and moist. I purpose naming those kinds which root the most readily and need to be planted the first June after the cuttings were taken, as such sorts may go in at one time, thus simplifying the matter of planting and frame room later on. The others, which require more time to make roots, should remain in the cutting bed for a year, when they could safely be planted out the following April. During the summer and autumn take the lights off when it is seen that all that are going to thrive have formed roots, as some varieties after taking six months to callus require a still longer period after that to make roots freely. The advantage of using two frames instead of one is now obvious.

First list for early planting.—Retinospora plumosa, Cryptomeria elegans, Thuiopsis borealis, Thuia Lobbi, Cupressus erecta viridis, Golden Yews, Thuia occidentalis, Escallonias macrantha, Veronica Andersoni, Laurustinus, Fabiana imbricata, Garrya elliptica, Buddlea globosa, Cotoneaster Simmondsi, Kerria japonica, Lonicera reticulata aurea, Ampelopsis Veitchi, and A. hederacea.

Those which require a longer time to form roots.—Wellingtonia gigantea, Cupressus macrocarpa, C. gracilis, C. Lawsoniana, Thuia Wareana, Retinospora plumosa aurea, Euonymus japonica aurea variegata, Lonicera fragrantissima, Ceanothus azureus, Jasminum nudiflorum, Pyracantha, and Myrtles.

Aucuba japonica is one of the most useful evergreen shrubs we have. It is best propagated in this manner. At the end of September take the cuttings, 4 inches long ; moderately strong side shoots are best, retaining a small heel. Insert them firmly in sandy soil about eight or ten in a 7-inch pot. Water gently to settle the soil firm about the cuttings. Plunge the pots in ashes in a cold frame. Little air will be required in the winter during the time they are callusing. About the middle of March plunge the pots in a gentle bottom heat, where roots will quickly form, when the plants should be hardened and planted out the following early part of June along with the rest, where they should stay the first year, and will then be ready for their permanent quarters.

The best of Laurels are the Caucasian, rotundifolius, common, colchicus, and the Portugal Laurel. The second named is the best for banks where a dense low growth is required or for forming hedges, being short-jointed and of a free habit of growth. If manure be added to the soil at planting time the colour of the leaves is much improved, as in poor soils they have a tendency to remain pale green, which deteriorates somewhat from its appearance, in the winter especially. Behind a north wall is the best position to root Laurels. Early in October the cuttings about 6 inches long should be slipped off, preferring medium sized shoots to large sappy growths. Chop out a trench with a spade about 3 inches deep, placing a layer of sand at the bottom, the cuttings being inserted about 4 inches apart. Fill in the soil, treading it firmly about the cuttings, digging the ground as the work proceeds, when the next row should be 10 inches from the first. The chief point is to thoroughly secure the cuttings in the soil, as if they are let loose roots cannot form. Previous to sharp frosts being expected it is wise to mulch between the rows with partly decayed leaves, as this prevents the ground becoming frozen hard, which when a thaw sets in renders the cuttings quite loose in the ground. After frost tread the soil about the cuttings firmly. For one season let the plants remain in their present position, when they may be transplanted, allowing more space to each. Irish Ivy, the best of all the Ivies for general use, may be propagated precisely in the same manner as Laurels, with the single exception that the cuttings may be cut into lengths of 8 inches, selecting the current year's growth and without the heel as advised for the Laurels.—S.

HARMFUL AND HARMLESS GARDEN MOTHS—5.

ENTOMOLOGICAL books tell us to seek the ghost moth, if we wish to see or catch it, about neglected churchyards, waste spaces, or railway banks, but Hepialus Humuli is not restricted to these, and, like other swift moths, occasionally visits gardens. We might expect to come upon it in any garden near Hop grounds, the species taking one Latin name from that plant. But though so styled, I have never been able to discover that the caterpillar does any noteworthy damage to the roots of Hops; though no doubt it occasionally feeds on them, nor do I find proof of other swifts being injurious to cultivated plants while they are in the larval state. Whether the ghost swift received its name because it haunts eerie spots, or from its white hue, is uncertain, but the mode of flight of the males is really curious to watch. One of them will seem to have chosen a spot, above which he vibrates like a pendulum, darting off now and then to a little distance, but returning. The female insects seldom fly till they deposit their eggs, which are dropped at random amongst the herbage. July is the month to look out for these insect ghosts. The females are yellowish brown, or a dull brown, with some red markings. When we unearth one of the caterpillars of H. Humuli, we discover it has a greyish white body, the head being brown, shielded by a horny plate. They are active, running backwards or forwards along the burrows, and live about twenty months, becoming chrysalids in April. A very singular variety in colour of this moth has been observed among the Shetland Islands; some of the specimens are also much larger than the southerners. Though called a swift, it is not so rapid as are others of the tribe.

About this time a gardener may chance to notice a freshly tarred paling decorated with numerous specimens of the common swift, Hepialus lupulinus. (It has, however, no special right to this Latin name, since the caterpillar feeds on almost any root that is handy, but seems to prefer those of a Lamium or Sonchus). I used to think these swifts got stuck upon palings owing to their heedless flight. I conclude now that most of them are attracted by the smell of the tar. It is much smaller than the ghost, brownish in hue, having a few whitish patches. Though abundant in our island it is local abroad. Less in size, the caterpillar resembles that of the ghost moth, and, like that, lives through two winters.

Attracted by the lights of a house, the beautiful or wood swift (H. sylvinus) may be seen fluttering about a garden on an August evening. It is one of the larger species, with wings of orange-brown, varied by white and dark brown tints. The caterpillar feeds on the roots of Dandelion or one of the Sorrels. One more swift may be mentioned, the golden species, H. hectus, which, soon after sunset begins a rapid, sportive flight, reminding us rather of a butterfly's movements. Mr. Barrett, when collecting a series for a local museum, discovered that the males exhale an agreeable odour, which is like that of ripe Pine Apple. It is the smallest British swift. The caterpillars live on the roots or young shoots of the common fern or brake.

There is a pleasant Kentish village near the Thames where a line of houses, with large gardens in front, occupy the side of a slope, below which are extensive fields. Along these gardens, on a bright June day, fly briskly little parties of the six-spot burnet moth (Zygæna filipendula), looking beautiful in the sunshine, the fore wings being deep glossy green, the hind pair crimson, body and antennæ black. Their breeding place is the meadows below the hill, where the caterpillars feed upon Clovers and Trefoils; but the gardens attract the winged insect, either because the moths prefer the higher ground or they are drawn to them by the display on the flower beds. Others of the burnet tribe sometimes visit gardens, but all are simply ornamental species, doing no harm in the caterpillar state. Entomologists of the Georgian period used to capture in Kensington Gardens the green-and-gold forester moth, allied to the burnets, but it has vanished, probably it has gone from the London suburban districts. These pretty moths are not very active, and are occasionally seen about gardens of the south, reposing on some large flower, such as that of the Mullein. It is upon Sorrels the forester caterpillars chiefly feed.

A funny little moth, often abundant in July, was named by some old entomologist the short-cloaked, or Nola cucullatella. When the insect is at rest the folded wings form a sort of triangle, but the pale grey wings, streaked and spotted, are not very suggestive of a cloak or hood. You see one upon a leaf, the next moment it has vanished, having skipped to another leaf; in a short time it moves again, then at length it settles down quietly. Its caterpillar occurs upon Blackthorn in hedges, also it feeds on the leaves of Plums, but it is not seriously harmful.

We have some British moths called the footmen. This odd appellation may have been given to them because of the habit the insects have of tumbling to your feet if alarmed, folding their wings as they drop, and keeping still for some minutes. They secrete themselves sometimes in garden shrubs, perhaps to escape their bird enemies, but most of them, while caterpillars, live upon tree lichens. Not uncommon, even in London gardens, is the familiar smoky tinted and yellow species, Lithosia lurideola, occurring from June to August. Its caterpillar eats the leaves of Clematis and other plants; it is black and hairy. Another that has been seen amongst gardens is the larger, four-spotted footman, L. quadra. The grey, red-spotted caterpillar eats lichens on forest and fruit trees during spring.

Every gardener has made the acquaintance of some one or other of the tiger moths. The tribe is one that is both conspicuous and abundant. Several species, indeed, rank upon the list of our enemies, but it may be that they have a worse character than they merit. The name sounds formidable, yet they are amongst the meekest of moths, and their tigrine peculiarity is only shown by the spots which adorn the wings of most. This is notable, however, that the loose hairs of some of the caterpillars, or else an exudation from the body (for the point seems still to be somewhat doubtful), have an irritating effect upon the skin of sensitive persons. Even a contact with the cocoon of the great tiger moth will suffice to leave unpleasant results for hours. We may take this, the Arctic caja, as a good representative of them. Though the moth is not so frequently seen as the caterpillar, yet its colouring of black, brown, scarlet, and white is conspicuous, but it flies little, even at night, preferring to crawl about in the herbage. Some say the female deposits 600 or 700 eggs; if so, the species would increase its numbers, were there not some check. It has parasitic enemies, and as the caterpillars hybernate, probably a part of each brood is liable to die off in our ordinary winters, even though they have a hairy garb. "Bear" is a name applied to this, and to some of its relatives, in several countries. Their coating does, no doubt, protect them from most insect-eating birds.

During the autumn tiger caterpillars are little noticed, either in the country or gardens. About April they are fully active, and when touched roll into a ball, outside of which we see only the grey and brown hairs covering the body. They feed upon various garden plants, but seem specially partial to Lettuces and Strawberries. All of us have observed a much smaller species of this family, called the white ermine (Arctia menthastri) which flutters about on June evenings, dropping its pearly eggs without exercising any apparent choice of plant, and, as the caterpillars are apt to rove, they can change their food when they like. They are both brown skinned and brown haired, having a pale line down the back. Tall Sunflowers and Hollyhocks are acceptable to them; Pelargoniums and Carnations, of lower growth, are also visited, but they do not seem to be partial to the Chrysanthemum. Then there is the buff ermine, A. lubricipeda, which, as a moth, resembles the preceding in markings, the ground colour being a dull yellow. It is a sluggish insect, but the caterpillar can be brisk; indeed, from its speed in rushing out of danger it got the Latin name, meaning "slippery-footed." Usually it feeds upon wayside weeds, and occurs very often upon Docks.—ENTOMOLOGIST.

EPILOBIUM OBCORDATUM.

THE dwarf-growing Epilobiums, many of which are suitable for growing on rockeries, are not so well known in gardens as some of the taller species and varieties. Amongst the former E. obcordatum (fig. 14) may be mentioned, for although by no means a new plant, it is worthy of extended cultivation. It is a native of the Rocky Mountains, where it is found at over 1000 feet above sea level. It is perfectly hardy in our gardens, flowering incessantly from June until the present time. Dry sunny slopes are the places to be chosen on which to plant it. It soon covers the place allotted to it. The flowers vary from three to five on each stem, over an inch in diameter, and of a lovely dark rose colour. It is easily injured by damp during the winter season, and should be protected by a "cloche" or piece of glass raised above the plant, so as to allow free access of air. A difficulty is often experienced in propagating it, but in heat it roots readily at this season, when the cuttings have been thoroughly ripened.

CULTURE OF HERBACEOUS CALCEOLARIAS.

CULTIVATORS of herbaceous Calceolarias find the mouth of July the best time to sow the seed. A portion is usually sown about the beginning or middle of the month, and a late sowing at the end. This gives a succession of plants, varying in size, the later plants prolonging the season of flowering.

Calceolaria seed is very fine, requiring considerable care in transferring it from the packet to the seed pot or pan prepared. Wide seed pans are the best receptacles. They should be perfectly clean and dry. Crock them carefully with three layers of potsherds, the largest at the bottom, smaller over them, lastly a sprinkling of fine, those with the dry dust riddled out being suitable. On this drainage place a thin layer of damp moss. The pans are then ready for the soil, which should be of a light, fine character, a mixture of leaf soil, a little fresh fibrous loam and old potting soil, with a free admixture of sand, answering well. Use the compost in a slightly moist state, making it firm, fine, and level on the surface. Give a gentle watering through a fine rose, allowing drainage to take place before sowing the seed. If the pan is allowed to drain half an hour this will effect the purpose.

Sprinkle a little fine sand on the surface in order that a regular distribution of the seed may be carried out. Avoid sowing too thickly. Another fine sprinkling over the seeds will suffice to cover them. Place a square of glass over the pan, and darken it with moss or paper. No heat other than that obtained in a closed frame is necessary for insuring germination. This will take place in about ten days, no water being applied to the soil in the meantime. The covering of glass with moss or paper prevents evaporation.

As soon, however, as the seedlings appear the shading material must be removed, all the light possible then being given other than hot sunshine, from which the seedlings must be screened. Afford air by tilting the glass, which in a short time may be dispensed with. Stand the pan on a pot close to the glass of the frame. With a free circulation of air, avoiding draughts, the seedlings soon strengthen. When they have attained to a size showing the second leaf, prick them 2 inches apart into pans or boxes The compost for them may be similar as for sowing the seed. Return to the frame, lightly syringing the seedlings daily in preference to heavier watering until they are well established.

When the plants begin to touch each other they will be ready for potting into small sized pots, using compost containing a little extra leaf soil Shading from hot sunshine must be continued. The next shift may be into 4½-inch pots, adding to the compost a little decomposed and well pulverised cow manure. Pot more firmly each time. Drain the pots effectively. Subsequent shifts should take place as the pots become filled with roots.

From the time the plants are transferred to pots, a moist base for these to stand upon must be provided, but it ought not to be far from the glass. The cooler Calceolarias can be grown the better, because a cool temperature insures a moist atmosphere, which is the most conducive to healthy growth. A constant supply of air is essential, but it must not be admitted in the form of sharp cutting draughts at any stage. During the cool nights of early autumn, when the air is calm and the dews heavy, Calceolarias are much benefited by the night exposure. Heavy rains are not beneficial, as they saturate the soil, preventing free root action. In the daytime place the lights over the plants again.

An excellent base for the plants to stand upon is coal ashes, inasmuch as it holds moisture and largely excludes worms. Watering must be conducted carefully, supplying just enough as the plants require it individually. Ascertain by examination of the surface soil or the ring of the pots when it is required. Then give a fair supply, waiting until the pots again ring when rapped sharply before supplying more. Lightly syringing the foliage is helpful to growth, and prevents green fly obtaining a foothold. Use the coldest water possible both for watering and syringing.

Should green fly appear, even to a small extent, vaporising with nicotine or fumigating with tobacco paper ought to be resorted to for destroying the pests. With good treatment on the lines indicated during the early stages and in the autumn months the foliage usually remains perfectly clean. Poor root action, checks to growth from dryness and overwatering, together with an arid atmosphere, are the chief causes of green fly invasion. Preventing the pests attacking the plants severely ought to be the rule. In the winter time Calceolarias are moved from frames to greenhouses in order that they may be safe from hard frosts. They will endure, better than any succulent, soft-leaved plants, a few degrees without

FIG. 14.—EPILOBIUM OBCORDATUM.

injury. It is on their removal to these positions that aphides are liable to appear and increase, especially if the structure be dry and not so cool as it ought to be.

Frame treatment continued throughout the winter is better than transferring the plants to dry shelves in houses. If in frames the plants need not to be so close to the glass as in summer and autumn. Rather deep frames are best. Material may be packed round the sides to ward off frost, and over the top in the severest weather. Dry leaves or strawy manure are useful as protection. The two dullest months of the winter may be passed without affording any shift, but in February and March those intended to attain to a larger size should receive more root room. A substantial compost formed of fibrous loam, leaf soil, and cow manure, with sand and a little charcoal, ought to be prepared.

In potting, the compost employed is best moist, but not wet. The ball of roots ought also to be thoroughly moist throughout. Make the new compost pressed round the old ball as firm as the latter. It is desirable to give liberal but not large shifts; 8-inch pots are suitable for the final shift.

When the pots in which the plants are to bloom are becoming full of roots weak applications of liquid manure will give an impetus to growth, and incite strong flower stems. Let the

liquid be clear, and not too frequently given at first ; once a week is ample.

As the flower stems advance tie them out regularly to neat light stakes. Still keep the plants cool, regularly supplied with fresh air according to the weather, duly watered as necessary, and dewed over daily, except when the conditions of temperature and atmosphere render any of these details undesirable.

Before the plants flower give them a vapourising to destroy possibly lurking aphides, which might increase and rapidly injure good and floriferous plants.—E. D. S.

PLUM TREE ENEMIES.

I HAVE received from "W. S." specimens of fungus-affected Plum trees for examination, also insects which attack the trees, and it will be convenient to refer to them separately.

Brown Rot.

Not so much seems to be known about this destructive fungus by scientists in this country as appears desirable, possibly because they have not often had materials for examination, and if a "mere gardener" who has examined many specimens can assist the learned in a small degree, he will be grateful ; while if he is wrong, he will be equally grateful by being set right on the subject.

The portions of stems received range from 6 to 9 inches in circumference. Both branches and roots are infested by the brown rot of stone fruits, as readily detected by the discolouration produced in the tissues by the mycelial hyphæ of the fungus (Monilia fructigena) which traverses the alburnous layer or young wood last formed outside the stem, branch, or twig next the inner bark, and thus destroys the cambial layer, causing the collapse of the affected trunk or limb. The mycelial hyphæ also attack the soft layers of wood, the branching mycelium passing through the hard parts in places, and the affected limb, when cut through, appears to have brown and whitish zones alternating, but not all round the stem, or only so in places.

On a growing branch the bark is found to be quite clear and white, but immediately beneath the cambial layer and young wood of last year are seen streaks of brown, and a longitudinal section shows the threads of the fungus. These proceed very slowly and horizontally of the tissues, hence the branch does not become quickly girdled ; indeed, the fungus may live in it for years, yet sooner or later the mycelium creeps round the alburnous tissues of the branch, when the part above dies for lack of nourishment. This usually occurs in the early part of summer, the leaves and fruit withering. When the fungus attacks a tender growth it soon dies, being quickly girdled beneath the bark by the mycelium. In bad cases it attacks the roots, and the trees die outright. The mycelium in this case does not penetrate the woody tissues, but merely the cambial layer or formative cells between the inner bark and outer wood. Thus the life is taken out of the tree, and the growths only push a little in the spring and then go off.

The fungus is most malignant on the Plum, and chiefly on the robust-growing trees. It is commonly referred to as dry canker, but there is no shrinking and destruction of the bark as in canker caused by Nectria ditissima var. prunaria, nor are there any outgrowths ("fruits" of the fungus) as occur under attacks of canker fungus sooner or later. The most left of brown rot fungus attack on wood are minute masses of felted mycelia, called sclerotia, and from these spring the conidial (one form) condition, by means of which the parasite is spread. Its commonest fructifying state is found on fruits, and this form I have not succeeded in transferring to firm wood ; but the germ-tubes of the spores readily pierce the soft growths of most stone fruits, and may kill them in a month to six weeks. Though the fungus attacks Apples and Pears, spoiling bushels of fruit in some seasons, it appears powerless to affect the wood of those trees. It, however, attacks the Apricot, Cherry, Nectarine, Peach, and Plum, these being its wood-"hosts," and in them it lives by its mycelial hyphæ as a perennial. It may lie dormant for a long time, but sooner or later it wakes up and quickly compasses the destruction of the limb or tree.

The parasite, as a wood infection, can only be got rid of by removing the affected part to sound wood below. This is readily detected by its clear colour—not being stained in the rings by dark brown, as the affected wood is more or less irregularly. When in the stem there is nothing for it but to uproot the affected tree, as the fungus will descend as well as ascend and destroy the roots. Shrinking follows the destruction of any part, but it should be remembered that the mycelium is ahead of this, therefore cut well below it so as to get the parasite clean out.

When the attack is only on one side of the stem it may be possible to cut the mycelium out by making an incision well into the sound parts all round the shrunken patch ; but this is very doubtful in effect, as the mycelium, unlike that of canker, is not confined to the cortical and immediately underlying tissues, but strikes deep into the older layers of wood, and acts in a vertical more than horizontal direction. In such case wash the wound with a paint formed of Stockholm tar and paraffin oil, only using sufficient of the latter to form an ordinary paint consistency, applying with a brush. Allow it to act for a short time, and then dress the wound with a composition formed of clay, dried and pounded, and then formed into putty consistence with soluble petroleum, making level with the bark. This is useful against canker, of which there is a scar on one of the stems ; but that has not killed it, for the tree was getting the better of the canker, as seen by the new bark that had formed around the circumference of the wound, and there was neither mycelium nor any fruits.

In addition to clearing away the affected parts and the dead trees, burning them, we should apply a dressing of basic slag phosphate, 10 cwt. per acre, 7 lbs. per rod, as soon as all the leaves are down, and 2½ cwt. of kainit per acre, 1¾ lb. per rod, along with it or separately, and point in lightly. Early in spring apply 2½ cwt. of mineral superphosphate, 37 per cent. soluble phosphate per acre, 1¾ lb. per rod. This has been found useful, and if a heavy crop of fruit set, promptly supply 2½ cwt. per acre, 1¾ lb. per rod, of nitrate of soda, preferably at twice, the first time as soon as the fruit has set, and the second when about a quarter grown.

Against brown rot generally spray with Bordeaux mixture, at a strength of 4 lbs. of copper sulphate, and 4 lbs. of lime to 50 gallons of water, just before the trees come into blossom, again as soon as the fruit is well formed, repeating twice at intervals of about a fortnight. This is to protect the fruit, but the fungus rarely attacks the fruit of the Plum seriously in this country. Once spraying with sulphate of copper, 1 lb. to 25 gallons of water, in the spring before the buds commence swelling, appears all that is necessary in this country to keep the fungus from the wood, where it is most malignant in stone fruit trees in our climate. Of course the spraying will not cure the trees already infested.

The Plum Tree Borer Beetle (Xyleborus dispar).

There is no doubt about the identity of the "insects" sent. They cause injury by driving their tunnels in the wood immediately beneath the bark, and their attacks are a consequence of the unhealthy condition of the trees, the stems having become dried to a great extent, and thus admitting of the penetrations of the pests. They never attack quite healthy trees, as the sap drowns them out as well as their larvæ, but trees not vigorous soon succumb to their attacks, as what they do not effect in girdling the stem one year they finish off the next.

The best preventive of attack is to dress or wash the stems with a solution of soluble petroleum about the beginning of June—in forward seasons earlier—and repeat occasionally up to about the middle of July, then again at the end of August and beginning of September ; but there are not often two broods in this country. Once the pest gets hold it is difficult to clear away from old plantations. It will content itself for a time on old limbs, but if anything happens to render the trees unhealthy they are soon taken possession of, and may be ruined.

To clear the vermin out cut down any trees that are not wanted, divide them into lengths of about 2 or 3 feet, lay them on damp soil or set in the soil, doing this in the spring, and leave until the beginning of September, then clear away and burn. If there are any beetles about they will find these baits, and are easily got rid of. We have not found any plan equal to this, but of course the cause never ought to arise, as the beetles cannot make anything of trees full of sap and vigour. This I have proved by various experiments extending over many years.—G. Abbey.

ROYAL HORTICULTURAL SOCIETY.

Drill Hall.—July 27th.

The exhibits at the Drill Hall on Tuesday were very bright, though not particularly numerous. The finest exhibits were those of Messrs. H. J. Jones and J. Veitch & Sons, who exhibited a group of plants and a collection of Gooseberries respectively. Orchids were by no means numerous.

Fruit Committee.—Present : Phillip Crowley, Esq. (in the chair) ; with Messrs. J. Cheal, A. F. Barron, T. J. Saltmarsh, J. H. Veitch, G. W. Cummins, A. Dean, W. Bates, W. Farr, G. H. Sage, G. Wythes, J. Smith, F. Q. Lane, W. J. Empson, R. Fife, and J. Willard.

At the last Drill Hall meeting Messrs. J. Veitch & Sons, Ltd., Chelsea, sent trained Gooseberry plants. On this occasion no plants were in evidence, but instead a superb collection of fruit comprising one hundred varieties. The specimens were in splendid condition and made a most interesting display. Amongst the varieties were noticed Whinham's Industry, London City, Surprise, Rockwood, Admiral Boxer, Progress, Telegraph, Ironmonger, Duke of Sutherland, Yellowsmith, Leader, Conquering Hero, Champagne, Railway, Safety, Tiger, Traveller, Gipsy Queen, Rough Red, Bobby, Pretty Boy, Criterion, Leviathan, Crown Bob, Random, Drill, Beauty, High Sheriff, Broom Girl, Lancashire Lad, Whitesmith, Keepsake, Candidate, Golden Drop, Lord Scarbrough, Glory, and Trumpeter. The same firm also sent Morello Cherries, Currants La Constante, Haughton Castle, Red Dutch, La Versaillaise, Warner's Grape, White Dutch and White Transparent, with a dish of Figs Negro Largo, and Nectarines Précoce de Croncels and Early Rivers (silver-gilt Knightian medal).

Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, sent French Beans, Veitch's Early Favourite and Wythes' Early Mohawk. The plants were staged to show their earliness and cropping qualities when grown in the open air. The seeds of the first named were sown on May 3rd, and pods were ready on June 15th, and the latter were sown on May 21st, and ready on July 10th. Both varieties have been honoured by the Society, and are excellent. Messrs. Kelway and Son, Langport, sent a dish of Duke of Albany Pea and Bunyard's Exhibition Longpod Bean, each in capital condition.

Melon Hardwicke Beauty was staged by Mr. J. Taylor, Hardwicke Grange, Shrewsbury, and specimens of the Wineberry came from Mr. Cundey, The Warren House, Cobham, Surrey. Mr. J. McAinsh, The Gardens, Leeds Castle, Maidstone, send six splendid fruits of Sea Eagle Peach, and Messrs. W. J. Stokes & Sons, Trowbridge, pods of a Pea

named Hero of Trowbridge. Messrs. J. Carter & Co., High Holborn, exhibited a collection of about eighteen varieties of Turnips, including Cardinal, Red Top Stone, Golden Ball, Early Munich, Jersey Lily, White Model, and others.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. W. Atlee Burpee, H. B. May, R. Dean, G. Gordon, G. Stevens, T. W. Sanders, J. Hudson, J. F. McLeod, W. Bain, J. Fraser, C. E. Shea, J. Walker, C. E. Pearson, H. J. Jones, J. D. Pawle, G. Paul, D. B. Crane, E. Mawley, J. Fraser, and H. S. Leonard.

Mr. H. J. Jones, Ryecroft Nurseries, Hither Green, Lewisham, arranged down the centre of the Hall a long undulating group, which produced a unique and beautiful effect. This is the first time we have seen plants arranged in this style at the Drill Hall, but it will be a matter for regret if, when space permits, the plan is not followed up. Both plants and arrangement must be good, or the effect will be very bad instead of very good. Mr. Jones' group comprised excellently grown specimens of double and single Begonias, Lilium speciosum, with Caladiums, Palms, and Ferns, all placed in an artistic manner (gold medal).

Mr. W. Bain, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, sent examples of Gladiolus Lemoinei, some splendid spikes of Pentstemons, Crinums Powelli, and Powelli alba, with three varieties of Phloxes. Messrs. Paul & Son, Old Nurseries, Cheshunt, staged Roses, Coreopsis, Phloxes, Spiræa kamtschatica, and other hardy flowers (silver Banksian medal). From Messrs. Barr & Sons, Covent Garden, came the customary display of such hardy flowers as Pentstemons, Phloxes, Delphiniums, Campanulas, and Liliums (silver Banksian medal).

Blooms of double Begonias were exhibited by Mr. Baylor Hartland, Cork. Several varieties of good quality were included in the stand (silver Flora medal). From Mr. H. B. May, Upper Edmonton, came a splendid collection of Pterises, comprising many varieties (silver-gilt Flora medal). Messrs. F. Sander & Co. staged Watsonia Ardernei, Dipladenia atro-purpurea, Exacum macranthum, and Lilium philippiense. A small collection of Dahlias was arranged by Messrs. J. Cheal and Sons, Crawley, including single, Pompon, and Cactus varieties in good variety.

Messrs. J. Veitch & Sons, Ltd., staged an interesting collection of flowering shrubs, including Eucryphia pinnatifolia, Hibiscus Single Painted Lady, H. cœlestis, H. totus albus, Pavia macrostachya, Spiræa Anthony Waterer. The same firm also staged a box of Nymphæas of the choicer varieties, with flowers of the Rhododendron javanico-jasminiflorum hybrids (silver Banksian medal). Roses were staged by Messrs. W. Paul & Son, Waltham Cross, such varieties as Empress Alexandra of Russia, Sylph, and Enchantress being conspicuous. A few herbaceous Phloxes, also came from this source (bronze Banksian medal).

Messrs. Kelway & Sons, Langport, staged a magnificent collection of Gladiolus, including many varieties of the best quality. The flowers were large and the colours clear. Gaillardias also came from Langport (silver Flora medal). The Surrey Seed Co., Red Hill, sent Carnation Mrs. Moore Binns, a yellow scentless variety.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, De B. Crawshay, H. M. Pollett, H. Ballantine, F. W. Moore, F. J. Thorne, W. H. Young, H. J. Chapman, E. Ashworth, E. Hill, W. Cobb, and S. Courtauld.

Some beautiful blooms of Cattleyas were staged by E. Ashworth, Esq., Harefield Hall. There were several distinct forms, and a silver Flora medal was awarded. Mr. F. J. Thorne, The Gardens, Sunningdale Park, staged splendidly grown plants of Odontoglossum Schlieperianum, O. S. aureum, and O. aspidorhinum. Messrs. F. Sander & Co. sent a few Orchids, as did Messrs. J. Veitch & Sons, Ltd.; but, as has been noted, Orchids were staged in very small numbers

CERTIFICATES AND AWARDS OF MERIT.

Canna Miss Elsie Parkins (Paul & Son).—This is a handsome yellow coloured variety (award of merit).

Croton Shuttleworthi (J. Bugg).—This is a very handsome seedling. The long pendent leaves are narrow and slightly twisted. The colour is cream and green, with a rose midrib (award of merit).

Epilælia radico-purpurata (J. Veitch & Sons, Ltd.).—This is a charming bigeneric hybrid, resulting from a cross between Epidendrum radicans and Lælia purpurata. The sepals and petals are rosy buff. The broad flat lip has a yellow centre, surrounded by purplish crimson, paling to the colour of the other organs. Needless to say it is perfectly distinct (first-class certificate).

"*Geranium*" *Anna Bateson* (J. Davidson).—A dwarf-growing Zonal, with compact trusses of bright rose-hued flowers (award of merit).

Gladiolus Carlton (Kelway & Son).—A rich rose-purple flower of much beauty (award of merit)

Gladiolus J. G. Clarke (Kelway & Son).—Soft rosy purple is the colour of this variety (award of merit).

Gladiolus White Lady (Paul & Son).—A beautiful pure white variety (award of merit).

Gladiolus General Duchesne (W. Bain).—A magnificent variety. The colour is crimson suffused with blue. The throat is cream (award of merit).

Godetia gloriosa (Dobbie & Co.).—A superb rich deep crimson variety that is extraordinarily floriferous (award of merit).

Heliopsis Pitcheriana (Paul & Son).—A beautiful form. The flowers are very rich yellow (award of merit).

Hibiscus cælestis (J. Veitch & Sons).—This is a charming plant. The large single flowers are pale porcelain blue (award of merit).

Hibiscus Single Painted Lady (J. Veitch & Sons).—The colour of this is very delicate blush with a crimson centre (award of merit).

Nectarine Precoce de Croncels (J. Veitch & Sons).—An early variety with medium sized fruits. The flavour is rich and the flesh very juicy (award of merit).

Phlox Lord Raleigh (Paul & Son).—A fine variety with bluish purple flowers (award of merit).

Rosa rugosa atropurpurea (Paul & Son).—A very rich crimson variety of great beauty (award of merit).

Rose G. Nabonnand (W. Paul & Son).—A lovely variety with delicate salmon hued flowers (award of merit).

Veronica Le Seduisante (J. Veitch & Sons).—A handsome Veronica. It is very free in the production of its Royal purple spikes of flowers (award of merit).

CACTACEOUS PLANTS.

The silver Flora medal awarded for the best collection of these plants went to Mr. W. Bodkin, West Hill Place, Highgate, whose exhibit was diversified and interesting. Mrs. Chilton, Wealdstone, Middlesex, took the bronze Flora medal, and Mrs. A. Blogg, Croydon, the silver Banksian medal.

Mr. Bodkin was also successful in securing the premier award for twelve plants, followed by Mrs. Chilton and Mr. W. F. Gould, Bath. For six plants the prizewinners were Mr. W. F. Gould and Mrs. Carter, Tooting.

Messrs. H. Cannell & Sons, Swanley, arranged a fine collection, not for competition. The plants were splendidly grown and very interesting (silver Flora medal).

FUMIGATING WITH TOBACCO.

IN no particular is a display of patience and tact more requisite than in doing battle with the various pests which to many are a source of trouble and anxiety, but which the man who possesses tact takes as a matter of course, for he knows, how, when, and where to meet them. The appearance of green fly, thrips, scale, mealy bug, or red spider, on his plants, if they do appear, gives him no anxiety, for he applies the remedy or remedies, and it is done with; but then comes the question, What are the remedies? Gardeners differ in performing some of the most simple operations for destroying green fly, and with amateurs mishaps occur through misunderstanding or misapplying the remedies, which are set down as ineffectual, and are, with those who recommend them and the vendors, mentally consigned to the rubbish heap, if a more unpleasant situation does not happen to be before the mental vision of the disappointed experimentalist.

In the process of fumigating with tobacco or tobacco paper—for, in my opinion, both are equally safe and effective—I could never perceive the necessity of being in the smoke myself, or of seeing others inside the house with it, for apart from the fact of the operator being almost suffocated, the door has to be opened as, half-choked, he leaves probably before the work is complete. There is another objection—the smoke hangs about a person's dress, while the smell does not improve by age, and lasts for several days. To be inside the house during the operation is by no means necessary, as I have always found.

The various ways and means of fumigating which have come under my own immediate observation convince me that more depends upon the way in which the smoke is applied, and on adapting the quantity to the space to be fumigated, than on the material itself. I have used different sorts of tobacco and also tobacco paper, and find that nothing better could be wished; yet one is no better than the other. If I have found the leaves of plants marked or the insects not killed, I blame myself, and not the material, for that is entirely blameless. In the first place it is always best—at least, I have found it so—to fumigate towards night, when the house is shut up and there is no fear of the sun shining on it, and then, as it has been often recommended, it is better to smoke two nights in succession than to depend on one fumigation, especially when it is for thrips, because it takes a strong dose to kill these all at once, and the quantity of smoke necessary to do so may injure the plants; but when the insects have had a weaker dose it makes them sick, and before they have recovered a similar dose the following night settles them.

It is, then, worth while to take the measure of the enclosed space, and find out, if possible, the exact quantity of tobacco or paper that will give the required quantity of smoke. This is advisable, both on the score of economy and to save time and trouble in doing the work effectually. There is more tobacco wasted through doing the work ineffectually than many would believe. I have been surprised myself when told that 7 or 8 lbs. of tobacco had been used, or rather misused, for smoking two small houses within three weeks, and this in cases where the operators were supposed to understand the matter. I have found half a pound of tobacco, or the same weight of paper, quite sufficient for a house 30 feet long by 16 wide and 9 feet in height; and this made into two fumigations, with, perhaps, a trifle the most at the last performance. A pit or frame will require much less, for it must be remembered that the height makes a great difference in the quantity of material requisite, for the farther the plants are from the roof the denser the smoke should be. In a pit the plants are generally within a few inches of the glass, and it is in such structures that plants are generally injured from an over-strong application of smoke. It is, therefore, advisable to use but a very small quantity of tobacco in smoking pits and frames, and to increase the quantity if the dose is found ineffectual.

In applying the smoke, the plan I generally prefer is to take a common flower pot—a 6-inch is very convenient—and place it on a larger one that stands on the ground inverted, so that the apertures of both are

clear for the draught of air. Put in the upper one a few pieces of charcoal ignited, and when they are thoroughly alight tear up some brown paper and put in, and then put on the tobacco or tobacco paper, which will consume gradually and give out a good smoke. Another plan I have generally adopted with regard to small houses or frames, is to take some coarse brown paper, steep it in a solution of saltpetre, dry it, then spread out the tobacco on pieces 6 inches or a foot square, roll both together, and tie with twine or matting. Then suspend by one end and light the other ; let two or three of these be lighted according to the size of the house or pit, and let them smoulder. If properly done, this will be found as clean and effectual a method of fumigating as need be.—C.

ABUTILON CULTURE.

THESE plants are very showy, free growing, and easily cultivated. They are alike useful for ornament in the greenhouse and conservatory, for affording flowers for cutting, and for forming beds in the outside garden. The taller varieties are seen to great advantage trained to wires under roof rafters, not having the wires further from the glass than a foot, whilst as pillar plants they are effective, their drooping bell-shaped flowers in either case being seen to singular advantage. Whether as roof or pillar plants they are best allowed to grow rather loosely, so that the side branches may droop, and when they are becoming too numerous they may be thinned, a convenient method being to cut the flowered sprays back to a few joints from their origin, which serves the purpose of keeping the plants well home as well as affording a succession or continuance of bloom, the sprays loosely arranged in large vases having a very fine effect. Crowding, however, must be avoided, timely thinning and regulation of growth being practised in due course and with discretion, avoiding stiffness or formality as prejudicial alike to freedom of bloom and effect.

As roof or pillar plants Abutilons are perhaps best planted out. They succeed, however, very well in pots, which must be proportionate in size to the plant required. They give much less trouble in watering when planted out than if grown in pots. In the latter they require feeding with liquid manure to maintain them in good foliage, and even then they do not attain to the freedom of growth and fulness of bloom of those planted out. A border of 2 feet width and similar depth well drained, as abundance of water and food supplies is required when they are in free growth, with a compost of equal parts fibrous loam, leaf soil, and peat, with about a sixth of drift or crystal sand put in rather firmly, so as to induce a sturdy free-flowering habit, will grow these plants to perfection. Continually pouring on water is not watering but drowning, making the soil sodden and sour, to the destruction of the soft roots and small fibres, the plant becoming sickly and collapsing. Over-dryness on the other hand, if not so pernicious as over-watering, causes a check to growth, a loss very often of bloom, and always a loss of foliage, more or less detracting from the appearance of the plants. The right time to supply water is when the soil is becoming dry, and before it is so dry as to cause the foliage to become limp or flag afford a thorough supply, there being no fear of over-watering a plant when it is dry. There is danger, however, of giving a check that may bring down all or most of the flower buds if the watering is delayed too long, or water is applied at a much less temperature than that in which the plants are growing, or if over-strong manurial matter be given, which destroys the younger, softer, and more active roots or feeders. These are matters that may not often burden the careful cultivator, but they do occur nevertheless, though the cause of disaster is not often attributed to errors of culture.

Planted-out Abutilons will flower continuously if they have a temperature of 45° to 50° assured to them, the situation being light, and care being taken to keep up a succession of flowering wood ; but they are all the better for a rest in winter, the soil then being kept dry, but not so dry as to impair the vitality of the plants. If the wood shrivel it is too dry, which is not resting but starving plants to death. It is needless expecting such to break as strongly and make as vigorous growth as those that have been granted rational treatment. In February the plants may be cut back, each growth to a few joints of the old wood, and where extension is required firm well-ripened wood can be trained-in to fill it, merely cutting away the unripe points. Old worn-out wood may he displaced in a similar manner—*i.e.*, cutting out the old and laying-in the young wood. Plants that become bare at the base may be cut down, they breaking freely from the old wood. After pruning a gentle sprinkling over the foliage will encourage a speedy and regular break, and when fresh growth is made the plants, if in pots, may be repotted, picking away the soil at the sides and bottom of the ball, so as to reduce them about a third, which, if they are to be returned to the same size of pot, will admit some fresh soil at the base and sides, the roots being cut close back.

Those planted out should have the soil removed from amongst the roots, not disturbing the fibrous or main roots at the collar, and if in compartments the soil may be taken out at the sides, the roots cut back, and fresh soil added, in all cases making it moderately firm, for which it must be in a medium state as to moisture. Avoid soil that is very dry or very wet. Water carefully until the plants have made fresh roots, and indicate possession of the soil by pushing fresh growths freely, then water thoroughly as required, and feed with liquid manure or artificials, applied in a surface dressing of light lumpy decomposing material, such as old cow manure, which will attract the roots to the surface. The foliage and bloom will show the benefit in due course. The plants will come into flower in a few weeks, and continue through the summer and autumn, if not greater part of the winter, the house of course being kept as before stated at a minimum temperature of 45° to 50°.

Abutilons also form magnificent standards. The plants should be trained up with a single and straight stem to the height required, they appearing to great advantage when on 4 feet 6 inches to 6 feet stems for conservatory, whilst plants with 2 feet stems are charming for table decoration. Pots of 8 inches diameter will hold sufficiently large plants for table, but for the larger and taller plants 12-inch pots are little enough. The plants are allowed to grow somewhat taller than the intended height of the stem, so as to get solidified growth to where the heading is to take place, and then the heads are cut clean off, or laterals or side growths being rubbod off on the stem when quito young, leaving the leaves at their base, as they help in a measure to thicken the stem as it advances in height, relying on the uppermost two or three growths for the formation of the head. Stop those when they have two or three leaves, merely taking out the points of the shoots, and continue this as fresh growth is made until the plants have a dozen or more shoots, when they may be allowed to flower. This being effected hy midsummer, as it will if one-year old plants are selected, they being trained the previous year to form the stem desired, the plants will afford a fine display of bloom, and being seen on a level with the eye are very pleasing, and will keep flowering in a suitable temperature until winter. It is desirable to give them a few weeks' rest by keeping them drier and cooler, and from the middle of February to early March they may be pruned, cutting back to well ripened wood, the weak wood being cut away, and others may be left of such length as will form symmetrical heads, two or three joints of wood being ample to leave on plants that have well-furnished heads, or when a compact head is desired. The plants may be given a little extra warmth to start them into growth, damping occasionally, and when pushing fresh growths disrooting and repotting

Stopping may be resorted to when the growths are a few inches long, or if early flowers are wanted the plants may be allowed to flower at once ; if some are treated that way, whilst others are pinched, a succession of bloom will be secured. The pinched plants, however, form the finest specimens, shifting them into large pots immediately after they push a little growth after the last stopping, and when the roots have possession of the fresh soil feeding with liquid manure. Other plants treated similarly in a cool or ordinary greenhouse will afford a fine display by August, and during the late summer and autumn months. Neat bamhoo stakes to the stems will be necessary for the support of the heads.

The plants intended for table decoration must be well stopped, and must be kept in comparatively small pots and firm soil, well enriched with some fertiliser to induce a sturdy well-furnished floriferous habit. Young plants of the previous spring or autumn rooted stock are suitable for this purpose, and being duly stopped will form heads quite large enough by August. They should he grown in a low-roofed house or pit where they can be accorded plenty of light. When they become old and stunted they may be discarded for young plants, but the older plants are more floriferous than young, and in every way preferable for early flowering, as young plants cannot be had with a sufficiently furnished head before summer is well advanced.—A.

(To be concluded.)

NAPHTHALENE.

"THE Patentee" of paraffin-naphthalene emulsion must be congratulated on his commercial acumen with regard to that substance, for nothing more or less may be found in his critique on page 73. This being so, it is only necessary to allude to my having on former occasions referred to naphthalene in the *Journal of Horticulture* as, in soluble form, a very effective eelwormicide, fungicide, germicide, insecticide, and miticide, and also mentioning it as a substance out of which not one, but several, proprietary preparations might be made. Then the chemical formula of naphthalene passed unchallenged, and even the question of rendering naphthalene soluble, raised not so much as the ghost of "patent rights" in paraffin-naphthalene emulsion.

As to the "no personal" concern of your correspondent, there does not appear a word until my reference to a patent in respect of paraffin-naphthalene emulsion on page 48, and my definition of it as simply petroleum emulsion naphthalenised—the free trade soluble petroleum transformed into a protected article by the addition of one seventy-sixth of naphthalene. Then arises the shadow of my "imperfect quotations, muddled, and misrepresented instructions," to which I must take exceptions *in toto*, for if there has been any of those things, the definition of the substance paraffin-naphthalene emulsion must have been "incomplete." Besides, what does "imperfect specification" mean in the matter of a patent ?

I disclaim any intention of infringing "patent rights," for beyond rumour I did not know of their existence in paraffin-naphthalene emulsion, and had I been in possession of the facts as stated by "The Patentee" on page 73, my article on naphthalene (page 47) would have heen modified. Then the occasion would not have arisen for securing a free advertisement for a special article in which the "on-lookers," not the "bowlers," are mainly interested in having "free."

As for text-books on chemistry, I have only to say that not one to which I have access is even "a little out of date," but all are in exact agreement on every essential point. Hence, I do not mind being "completely insulated." Even the naphthalene-potassium of "The Patentee" stands clearly as $C_{10}H_8K_2$ in chemical text-books, but apparently "Patentee" lives not to "enlighten, stimulate and amuse."—G. ABBEY.

Notes & Gleanings

EVENTS OF THE WEEK.—Though the season of Roses is almost done horticulturists will still be busy amongst the several provincial shows, of which Southampton on Saturday and Monday, and Northampton on the latter day and Tuesday, are amongst the most important.

—— THE WEATHER IN LONDON.—Since our last issue went on to the machines rain has fallen heavily in the metropolis. On Wednesday, 21st, just as the pages were being finished a terrific storm was raging in the north of London. Almost daily since then there have been local thunderstorms with heavy rains, and these latter will do a considerable amount of good in suburban gardens.

—— BISHOPS STORTFORD SHOW.—One hundred and ninety-seven classes are particularised in the schedule of the show of the Bishops Stortford Horticultural Society, which is fixed for Wednesday, Aug. 11th. There do not appear to be any open classes, notwithstanding which fact the exhibition should be a good one. J. Barker, Esq., has kindly given permission to hold the show at The Grange. The Hon. Secretary is Mr. W. Smith, Bishops Stortford.

—— THE MANRESA VINE.—The famous Vine at Manresa House, Roehampton, the seven rods of which in the aggregate extend over a quarter of a mile, has this year ripened 1030 bunches of Grapes—good bunches, with fine berries of excellent quality, though, perhaps, not quite so well finished as when the crop was somewhat lighter. They have, all the same, been good enough for the Royal tables, large consignments having been sent to Windsor Castle to supplement the supplies of the Royal gardens during this season of abnormal demands and extraordinary consumption. No man in the kingdom will be prouder than Mr. M. Davis is—the planter of this remarkable Vine—"to serve the Queen" with Grapes.

—— BORDER CARNATION MRS. A. HARKETT.—This is a fine, admirably formed perfumed flower, colour rosy carmine, which the raiser, Mr. Harkett of the Rectory Gardens, Petersham, exhibited in bunch form at the recent village show. The variety is a robust grower, having grass of the character of the well-known Gloire de Nancy type. The flowers, though of good size, do not split the calyx, a remarkable characteristic almost in good sized Carnations now. I like the variety very much, and grown under the best conditions—for at Petersham the plants are simply border-grown—the flowers should rank amongst the very best of the colour. The hue is one of the most pleasing the Carnation gives.—A. D.

—— POTATO SCAB.—Potato scab was so prevalent in some parts last year that it was impossible to find in certain districts a sample of Potatoes entirely free from it. This disease greatly injures the appearance of the tuber, and entails much loss to the grower. Certain remedies were tried recently in Canada for the same disease. Three rows 66 feet long were planted with very scabby Early Rose Potatoes. The whole tubers in one plot were treated with a solution of corrosive chloride of mercury (corrosive sublimate), made by dissolving 2 ozs. of corrosive sublimate in 15 gallons of cold water; the Potatoes were allowed to stand in this liquid for two hours, drained, then cut into two-eye sets, and planted. Plot No. 2 was planted with Potatoes treated with a liquid composed of 1 lb. of bluestone (sulphate of copper), dissolved in three pails of water; the whole tubers were immersed for two hours in the liquid, then cut up and planted. Plot No. 3 was planted in the same manner with the untreated tubers. None of the "treated" Potatoes would have been considered scabby by the average purchaser. The bluestone treatment, however, was found to seriously injure the germination of the seed Potato, and only about 40 per cent. grew, and there was in consequence a small yield. Although the corrosive sublimate treatment did not completely eradicate the scab, the injury, says a contemporary, was very slight. The treatment with bluestone was nearly as effective in preventing scab as the corrosive sublimate; but the germination of the tubers was so badly injured that the crop was greatly reduced. Corrosive sublimate is a virulent poison when swallowed by man or beast, and great care should be used to prevent accidents; but no injury results from handling the fluid of the proper strength.

—— CYCLAMEN CULTURE.—"H. T. M., *Stoneleigh*," writes:—Please correct an error which appears in my article on page 70, as I am afraid it will mislead some of your readers. The paragraph I refer to reads thus: "When they show the second leaf is the right time to pot singly in thumb pots, keeping them on a light shelf in a *cool* temperature all winter." For cool read *warm* temperature. [The word "cool" was clearly written in the manuscript, and we did not feel justified in altering it.]

—— ISLE OF WIGHT.—The flower show in connection with the Royal Isle of Wight Agricultural Society was held at Ryde on Wednesday and Thursday, July 21st and 22nd. Both days, unfortunately, were showery. The number of entries fell below last year, but the exhibits were up to the average. The principal exhibitors were Messrs. Kent, Grist, Niblett, Brook, Goble, Wolfe, Price and Leak. Mr. Goble obtained for his excellent stand of Carnations the Isle of Wight Horticultural Improvement Association's Certificate for Cultural Merit.

—— NORTHAMPTONSHIRE HORTICULTURAL SOCIETY.—On Bank Holiday, August 2nd, and the following day the above Society will hold its sixteenth annual Show in Delapre Park, Northampton. As has been the custom in previous years an excellent schedule has been compiled, and the prizes offered in each division should bring together an admirable display of garden produce. There are open and restricted classes. In addition to the flowers, fruits, and vegetables there will be other interesting attractions. The Secretary is Mr. W. B. Troup, 5, Deangate, Northampton.

—— THE BEDDINGTON, CARSHALTON, AND WALLINGTON HORTICULTURAL SOCIETY.—The annual exhibition of this Society, probably the best of its kind in Surrey—the produce of allotments and cottage gardens—will be held on Bank Holiday, August 2nd, in Beddington Park, near Hackbridge Station, on the L.B. & S.C. Railway. A conference is to be held at five o'clock, at which it is announced that questions will be answered on any gardening subject, and advice given on any difficulties that may be experienced with flowers, fruit, or vegetables by Mr. J. Wright; while Mr. A. Dean will treat on the condition of cottage gardens and allotments, and make suggestions for future improvements.

—— TURNIP AND TAP-ROOTED BEETS.—I have specially noticed of late the general excellence of the Egyptian Turnip-rooted section this year. These roots figure prominently and well on exhibition tables in July. I cannot say so much for the tap-rooted varieties, for it is evident their time is not in July, and, indeed, hardly in August, except towards the end of that month. The pulling of these tap-rooted forms to exhibit in the summer leads to great waste, not only because the selected roots are too immature to be used, but so many others are pulled and rendered useless in the process of selection. Would it not be well that these tap-rooted forms be eliminated from schedules until later in August, as the Turnip-rooted forms are so much more in season at the present time?—OBSERVER.

—— SUTTON'S PEERLESS PEA.—Although I have had under my charge this season numerous very fine Peas, this variety is, I regret to find, not included. I met with it the other day under interesting circumstances—judging cottage gardens, and at Hook, Surrey, I was taken up a farm road to a couple of cottages occupied by cowmen employed on the farm. These men have to rise and commence work feeding and milking cows at 3 A.M., have a few hours for rest in the middle of the day, then resume work again about two o'clock, and keep on till late. It is a hard life, no doubt, but it is under such labour conditions as these that the men cultivate their cottage gardens. The soil, to make matters more difficult, is a very stiff stubborn clay, and when I recently saw it the surface was like half bricks, being baked into hard lumps. Yet the crops generally were, for such soil, excellent, and showed that any partial failures here and there were in no sense due to lack of labour or energy. It was in each of these gardens I found Sutton's Peerless Pea. The men had no doubt purchased some seed and shared them, for each one had a good row. The variety grows to 3 feet in height, is stout and sturdy, and a great cropper, carrying very fine, long, slightly curved pods, very handsome, and well filled. They quite took both myself and fellow Judges by surprise, and each made a note of the variety for next year's use. Although we had seen some good Peas before none equalled these fine pods of Peerless. It is very evidently a first-class addition to that desirable race—3-feet Marrow Peas, and should be universally grown. The peas are green, tender, and sugary.—A. D.

—— Red Oak. — The Wisconsin Red Oak has for several years taken high rank in furniture and finishing factories on account of its softness, adaptability to shop work, its lively colour, and figure. When plain-sawed it commands higher prices than any Oak, although quarter-sawed White Oak is more expensive. This Red Oak belt in Wisconsin is not wide, and at the rate the timber is being cut off it probably will not last more than five or six years. In the North-west part of the State, which is not yet opened up by railroads, there is a heavily timbered area which may contain much Red Oak, but it will soon be traversed by a railway from Duluth.

—— Foresight in Gardening.—One of the misfortunes of garden lovers is that they frequently plan to do more work than can be carried on successfully. Almost everyone who builds a house thinks he would like to have a nice garden, and the nice garden is consequently arranged. But when it is found, as it too often is found, that it requires a number of men, running up an expensive salary bill, to keep the place in good order, what was expected to be a pleasure becomes an annoyance and a bore. A small place well cared for and everything kept up nice and orderly gives far more satisfaction than an over-grown place that is a drag on the means of the proprietor. We know of a number of places, beautifully designed in the first instance, and which require some half-a-dozen hands to care for properly, dragging along with only one regularly employed, with perhaps an assistant, and even the money for this grudgingly bestowed. There is no comfort in seeking pleasure in this fashion. In all our operations we are too apt to think we can do more than we really can. In gardening matters it is especially so says Mr. Meehan, and he is right.

—— Violas as Town Plants.—These charming flowers are being more and more grown in the London parks, and it is impossible they could present the attractive appearance they have done throughout the season without them. One of the severest tests to which the plants have been subjected as flowers for towns is in a densely populated district in the East End of London—the Bethnal Green gardens of the County Council. It seems difficult to imagine closer and finer masses of colour than have been produced there throughout the season. The varieties which show to the greatest advantage are Yellow Boy, a glistening sheet of gold; Duchess of Sutherland, and William Niel, lilac mauve; Niphetos, one of the finest whites in cultivation for town gardens, and the small floriferous primrose yellow Grievei. The secret of success rests in well enriched soil, early planting, the prompt removal of fading flowers, and occasional copious supplies of water during periods of drought. The gardens, generally under the canopy of smoke, and Violas, perhaps, particularly are undoubtedly creditable to the manager, Mr. F. W. Wright, and such a bright and cheerful display would, under the circumstances, have been regarded as practically out of the question a few years ago. The neatness of the gardens, too, adds to their enjoyment by the crowds of visitors, who "live" in them so to say from morning to night. They are a boon to the denizens of the east.—A Northerner.

—— Root Tubercles.—Mr. W. R. Dodson, the botanist of the Louisiana Experiment Station, has been examining the tubercles on the roots of leguminous plants by means of which nitrogen is taken from the air and used as a food material for the plants. The experiment seems to indicate that each plant, or at most each genus of plants, will support only one kind of parasitic organism capable of developing root tubercles. For instance, a particular organism must be present in the soil if tubercles are formed on Alfalfa. The Cow Pea likewise has its peculiar parasite, and dozens of leguminous plants may be grown side by side and each develop its own specific tubercle. Nevertheless, several imported species have been grown and formed tubercles, although the plants were not found in this country and have never been grown in the soil, which seems to indicate that the organism must have been in the soil before the seeds were sown, as there could have been no inoculation from soil in which the plant had been previously grown. If this is true, the organisms are not dependent on any particular plant for their existence, although the plant may be dependent upon them for its fullest development. Their absence from some soils and presence in others cannot, therefore, be explained satisfactorily. While the tubercles have peculiarities of shape or appearance they do not present characteristics that enable one to distinguish them under the microscope, although there are probably as many varieties as there are species of leguminous plants. The fact is that much is to be learned on this important subject before farmers can inoculate their soils with the assurance of success with any given crop.—("Garden and Forest.")

—— Gardening Appointments.—Mr. John Bates, for the past twelve years head gardener at The Hayes, Stone, Staffordshire, has been appointed in a similar capacity to T. W. Twyford, Esq., Whitmore Hall, Newcastle-under-Lyme, Staffs, and enters on his duties on August 10th. Mr. J. W. Barnes, for six and a half years general foreman at Wroxham Hall, Norwich, has been appointed head gardener to Col. Keppel, Stratton Strawless Hall, Norwich. Mr. Jno. Turton, of Fulford, York, has been appointed gardener to A. T. Schreiber, Esq., Becca Hall, Barwick-in-Elmet, Leeds.

—— A Kew Hand-list.—Another hand-list of Kew plants has just reached us. This particular publication deals with tender monocotyledons, excluding Orchideæ. In the preface to the book it is said that "The scope of the contents of the hand-list, which are somewhat heterogenous, is dictated in great measure by convenience. It includes large groups of plants of great scientific interest which, for various reasons, are more attractive to ordinary cultivators than many which are comprised necessarily in a botanical collection. For this reason it is hoped that it may be found not less useful than its predecessors." Application for the book should be made direct to Kew; the price is ninepence.

—— Callicarpa purpurea. — Many very beautiful shrubs achieve a wide popularity, and then, for some reason that no one appreciates, there seems to be a lack of inquiry for them. In this list one may include the Callicarpa purpurea, which was introduced into America from Japan some fifty years ago. It reaches a height when fully grown of about 4 feet, and the numerous slender branches take a wand-like shape. In the early spring a cluster of rose-pink flowers appear in the axil of each leaf. These flowers are succeeded in the autumn by bright violet coloured fruit. This is probably the only plant that furnishes us with berries of this colour, and always attracts at once wherever grown.—("Meehan's Monthly.")

—— Sheffield Chrysanthemum Society.—The schedule of the exhibition that is to be held in the Corn Exchange, Sheffield, on November 12th and 13th, has recently come to hand. For many years now the Society has held excellent shows, the blooms staged in all sections being of splendid quality. This, however, is not to be wondered at, considering the generous prizes that are offered in several of the classes. For example, £18 is to be divided between four prizewinners in the class for twenty-four incurved in not less than eighteen distinct varieties, while a similar sum is allotted for twenty-four Japanese, the individual prizes being respectively £8, £5, £3, and £2 in each class. These here specified with several others are open to all comers. In addition there is a section open only to growers residing within a radius of twenty miles from Sheffield parish church, and in this prizes are given for groups of cut flowers, fruit, and plants. Mr. Wm. Housley, 177, Cemetery Road, Sheffield, is the Secretary, and to him all communications should be addressed.

—— The Exclusion of Fog from Hothouses.—Dr. Schunck, President of the Society of Chemical Industry, addressing the annual meeting of the Society at Owens College, Manchester, referred to the manner in which the atmosphere of large towns was poisoned by smoke, and to its ill effect upon the population. The great distress caused to those suffering from pulmonary complaints by the fogs so often prevailing in these towns had, he said, no doubt more than once suggested the possibility of filtering the air before allowing it to enter into our dwellings. The difficulties of such a device did not seem great in themselves, the real difficulty arising from the habits and prejudices of the people, who could not understand the possibility of ventilation except it be through windows and doors. In his paper on "The Effects of Urban Fog upon Cultivated Plants," Professor T. Oliver mentioned with favour a plan devised by Mr. Toope of Stepney, who caused the air entering his hothouses to pass through boxes containing trays with sticks of charcoal before impinging on the hot-water pipes, an out-draught being secured by means of "exhaust caps" placed on or near the ridge of the house. The plan, in Professor Oliver's opinion, was an efficient one. That any such plan would succeed in private houses as at present constructed was very doubtful. Dr. Schunck ventured to suggest, though he did it under fear of censure, that a moderate amount of smoke might actually be beneficial to vegetation by covering the leaves and other parts of plants with a thin coating of carbonaceous or tarry matter, thus rendering them unpalatable to insects. Of course, the amount would have to be exceedingly small, for if excessive they would soon experience deleterious effects, such as were seen in the scanty and blighted vegetation in the immediate neighbourhood of smoky towns.—("Gardeners' Chronicle.")

—— East Cowes Horticultural Society.—By the kind permission of J. S. White, Esq., Clarence House, East Cowes, the members of this Society visited Clarence House Gardens, which are in the capable hands of Mr. C. Martin, on Wednesday evening, July 21st. The conservatories, stoves, Orchid and Peach houses, vineries, and kitchen, fruit, and flower gardens were carefully inspected, and gave much pleasure and profit to the members. Mr. S. Heaton, Horticultural Instructor for the Isle of Wight County Council, then gave advice on the cultivation of many things they had seen, which proved instructive and interesting. On the motion of Captain Harvey (Chairman of the Society) unanimous votes of thanks were given the lecturer and the Technical Education Committee of the Isle of Wight County Council for the excellent series of lectures which had just terminated, and to Mr. White for allowing them to visit his gardens.

—— Garden Privileges Abused.—It is to be regretted that the desire of owners of beautiful gardens to share their pleasures with others less fortunate than themselves is so often obstructed by a few boorish people, who do not know how to behave. The great majority of those so favoured conduct themselves properly, but the few rude ones spoil the whole. The New York correspondent of the Philadelphia "Public Ledger" reports the following. The unfortunate facts find a counterpart everywhere. "The reckless riding of wheelmen through the grounds of wealthy gentlemen residing on the banks of the Hudson River has resulted in the taking away of that privilege. Quite recently Mr. John Jacob Astor was crowded into the ditch on his own estate by a party of rough riders, and at once he shut the gates of Ferncliffe to all wheelmen. Mr. Fred W. Vanderbilt has now followed Mr. Astor's example, on account, it is said, of a similar experience. The Astor and Vanderbilt places contain miles of the best roads in Dutchess County."

—— London's Open Spaces. — At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., the Earl of Meath (Chairman) presiding, it was announced that the Association had completed the laying out of St. James's Churchyard, Pentonville, by means of a grant of £600 from the City Parochial Foundation, and that the ground was opened to the public by Captain Penton, the freeholder, on the 6th inst.; that St. Matthew's Churchyard, Bethnal Green, was approaching completion, and would be opened on the 20th inst.; that the gymnastic apparatus granted by the Association had been erected at St. Nicholas' playground, Deptford, and that this ground would be completed and opened in about a fortnight's time. Progress was reported with regard to the laying out of the East Street site at Walworth, and it was stated that the Association had received the gift of a handsome drinking fountain for this ground from Mr. L. H. Isaacs. It was agreed to renew a previous offer to lay out Christ Church Churchyard, Blackfriars Road, and a disused burial ground in York Road, Walworth, provided their maintenance was secured. It was agreed to support schemes for the preservation of vacant sites near the Essex Road, Islington, and in Wandsworth, Bromley, and other localities, and to offer prizes for the best designs for durable yet artistic drinking fountains, costing not more than £50 and £100 respectively.—("Garden.")

—— Hardy Garden Flowers at Petersham.—At the recent village flower show, the second only, held in this charming Thames side locality, there were several collections exhibited of bunches of garden flowers, in which hardy perennials largely predominated. These made up very pleasing as well as interesting features that are worthy of wide emulation elsewhere. Yet I could but notice that several forecourt gardens close to the high road entered for the flower garden class were dressed almost exclusively in very formal fashion, with purely tender flowers. That is far from being a desideratum in flower gardening. But that hardy flowers should be well grown and shown in Petersham need not excite wonder, seeing that Mr. Aldridge, who has very extensive fields of hardy flowers, is one of the largest growers of these around London for market. He set up a fine collection in large bunches of flowers now in season, such as several Eryngiums, and also various Helianthuses, as well as Coreopsis grandiflorus, Pentstemons in variety, Gypsophila paniculata, Echinops ritro, Giant Daisies, Gaillardias, Achillea millefolium rosea and Ptarmica The Pearl, French Carnations, Stenactis speciosus, Heliopsis superba, Rudbeckias, and not least two beautiful forms of Lathyrus latifolius alba and rosea. In the competing collections there were also Galegas, white and blue; Lychnis chalcedonica, Tradescantias, Lythrum roseum, Monarda didyma, Campanula persicifolia, and others, all tending to show not only their summer decorative qualities, but how beautiful they are when set up in neat bunches. Of course amongst garden flowers Sweet Peas, Roses, and Stocks were found also.—A. D.

—— Lathyrus rotundifolius.—This seems to be the earliest flowering of the hardy Peas, beginning to bloom in early May. At this time it has stems 6 feet long, bearing a profusion of flowers of a deep rosy red colour, known sometimes as old rose. This Pea is also known, says the "Garden and Forest," as Lathyrus Drummondi, and is highly valued wherever grown, for, next to the white-flowered form of L. latifolius, it is probably the most generally satisfactory hardy Pea in cultivation, as the colour is a pure tone, which contrasts most pleasingly with the light green leaves. It is perfectly hardy, and may be increased from seed or by division.

—— Diervilla japonica.—Many of the garden Weigelas bear abundant flowers of good colour, ranging from a dark wine-colour to pure white, but somehow the habit of these shrubs is stiff, and they do not seem to mingle well with other shrubs. Diervilla japonica was raised from seed gathered by Professor Sargent from wild plants in various parts of Central and Northern Japan. It is a common shrub by the banks of streams and along the borders of mountain woods. Well-grown individual plants reach a height of 15 feet and a diameter of from 10 to 20 feet. This species is the only one which Professor Sargent saw, and he is inclined to believe that the three species of Maximowicz must be reduced to this one, which varies much in size, in the pubescence of its leaves, in the number of its flowers, and the length of the peduncles of its flower clusters. It is from different types of this wild species, perhaps, that all the garden forms have been derived. It is easily propagated, and it has been flowering for some weeks past in the Arnold Arboretum and along the Boston parkways. Certainly, says the "Garden and Forest," it is a more graceful shrub than the Weigelas of gardens as we know them, and it can be unhesitatingly commended for park planting. The flower clusters are sometimes long-stalked and sometimes nearly sessile, and they are rose-coloured, yellow, dark red, or nearly white on the same plant, since the flowers which are very pale when they open turn darker as they fade.

IMPRESSIONS OF CULFORD.

Many and varied are the attractions of this fine seat of the Earl of Cadogan, and though no notes were taken on a recent visit, impressions of some of the principal points of interest remain. The flower garden is very fine notwithstanding the dry weather now being experienced. The whole is enclosed by magnificently kept Yew hedges, and whatever their value from an æsthetic point of view, there is no doubt that very careful tending is necessary to create and maintain them in their present luxuriant condition.

The beds are charmingly arranged, filled to repletion, and present a mass of colours well blended. A good strain of East Lothian Stock is magnificent in its freshness and bright colour, while in small scroll beds and large vases the useful Madame Crousse Pelargonium is used with good effect. Roses are quite a feature, the best of the Teas, Noisettes, and Hybrids being well represented in large beds, while one or two varieties of Scotch Roses adorn the walls. Many fine Coniferæ are to be seen in the pleasure grounds, which are planted for effect, and coming to the conservatory a large collection of healthy Palms, and a finely arranged planted-out fernery, are interesting.

Everything in the kitchen garden denotes high culture and careful selection of varieties, to enumerate which would take far too much space. The walls are covered with fruit trees of all the leading sorts, some grand old giant Cherries—unfortunately beginning to give way—showing that gardening has long been in ascendancy at Culford. With admirable foresight Mr. Davidson has a lot of young vigorous trees that in a season or two will almost take the place of the old ones. Fruit under glass is largely and well grown. There are early Peach houses cleared of their fruit, others with beautiful crops now ready, and a large expanse of glass to later ones, that will carry on the supply after the outdoor fruit is over.

Without enumerating more, I must mention Victoria, Humboldt, and Pineapple Nectarines; Royal George, Lady Palmerston, and Grosse Mignonne Peaches, the immense crops of splendid fruit being too good to pass. Grapes are well done, some finely finished Hamburghs and Madresfields looking well in the early vinery, while the usual kinds grown for late work, as Lady Downe's, Gros Colman, and Alicante, were equally satisfactory. House after house is in equally good condition, and carrying equally heavy crops, but that these even are not enough to meet the large demand is evident by some hundreds of feet more fruit houses being built. Houses to delight any practical fruit grower, roomy, light, capitally arranged and ventilated, the new Carnation house also being admirably adapted for the culture of these superb plants.

Of Malmaisons about 2000 plants are grown, none of these being more than two years old, yet some are carrying fifteen or sixteen flowers of great size and substance. Five hundred of these plants were arranged in one house—a sight to be long remembered. Many points of interest are necessarily skipped in this brief note, but the condition of the whole place shows that Mr. Davidson has it well in hand, the unmistakeable impress of careful and well considered culture being everywhere apparent.—H. R. R.

Maréchal Niel and Medea.

It is a great mistake to suppose, as Mr. Williamson seems to think, that Maréchal Niel is not thoroughly perpetual in the open ground if properly treated. It only requires to be pruned intelligently, and to have the shoots of the year well ripened and thoroughly protected from frost. I have staged it in some quantity at every show this year from my five or six standards in the open, and they have still plenty of buds in all stages of development, many just forming. For the open air alone I do not think anyone besides Mr. Williamson would venture to compare Medea with it.—W. R. Raillem.

Roses at Gateford Hill.

On calling at Mr. H. V. Machin's, Gateford Hill, for the first time, I was much interested in the magnificent show of Roses which were ably described in the *Journal of Horticulture*, March 6th, 1896. The garden Roses were superb, better than I have seen them before. H.P.'s were showing good flowers on cut-backs, the maidens not being forward enough for the early shows. The cut-backs have given a good account of themselves, as during the past fortnight, finishing with the N.R.S. Show at Norwich, thirty-six stands were exhibited, and thirty-four prizes (eighteen firsts) and three medals obtained, which cannot be termed a bad record.

The Machin Judging Card.

The Machin judging card is the most simple and useful one for judging Roses or Chrysanthemums by points with which I am acquainted. No judge ought to be without it. If not generally known, it may be useful to readers of the *Journal of Horticulture*.—S., *Yorks*.

Comments—Garden Roses.

Garden Roses were, as usual, a feature of much attraction at the Crystal Palace, although it was only in these that the lack of competition was seen, as in the leading classes there were only two exhibitors. Mr. H. V. Machin of Worksop again won a cup given by the Right Hon. Lord Penzance for eighteen bunches, amongst which were Camoens, Marie Pavie, Homère, Gloire de Polyantha, Red Damask, Paquerette, Rosa Mundi, Madame Pernet Ducher, Bardou Job, Bennett's Seedling, Marquis of Salisbury, Cecil Brunner, and others, prettily and tastefully arranged. There was a very close competition in the nurserymen's class for thirty-six varieties between Messrs. Paul and Son of Cheshunt and Messrs. Cooling & Son of Bath, it being ultimately decided in favour of the former.

I subjoin, through the courtesy of Mr. G. L. Paul, a list of the flowers exhibited in their first prize stand, as it will be a safe guide to anyone wishing to cultivate these charming flowers:—Seedling H.T. Dawn, a very pretty flower, with a charming shade of pink running through it; Rugosa Blanche Double de Courbet, the best of the seedlings which have been yet raised of this character; W. A. Richardson, Crimson Rambler, Moss, Blanche Moreau, Camoens, Mons. Desir, Mortetti, Marquise de Salisbury, Andersoni, A. M. de Montravel, Gloire de Polyantha, Madame C. Guinnoisseau, Rosa Mundi, Rosa Alba, Bardou Job, Rug. Rose Apples, Hebe's Lip, Madame G. Bruant, Alister Stella Grey, Reine Olga de Wurtemberg, The Garland, Rug. Imbricata, Ma Capucine, White Pet, Lucida, C. Soupert, Dominil Boccardi, Mignonette, Waltham No. 3, Madame C. Worth, Madame Falcot, Kakanlik, Perle d'Or, Madame E. Notte, and Bennett's Seedling.

As I have already said, the competition in these classes was not very keen, and I think there are two reasons for this; one is that they are only flowers for large gardens. It is true that every real lover of the Rose will grow some of them, whether his garden be large or small; but that is a very different thing to growing a sufficient number to cull from for exhibition. Another is that they are very difficult and expensive to bring to the place of exhibition, and I think more encouragement in the shape of prize money should be given to the amateur classes.

Medal Roses.

In looking over an exhibition where the general character of the flowers is so uniformly good, it is not easy to select any of very superior merit, and we naturally look to what the judges have selected as the best Rose in each division. The bloom of Muriel Grahame was undoubtedly one which the French would call *hors ligne*, or one of exceptional merit. It was exhibited by Mr. Lindsell, and fully justified all that has been said in its favour. The other flower which obtained a medal for the best H.P. or H.T. was a very beautiful bloom of Kaiserin Augusta Victoria. It was a very beautiful bloom, no doubt, but as it seems to me, as it has done to others, to be nearly, if not quite, a pure Tea, I grudge the honour given to it; but in saying this I do not wish to detract at all from the merits of the flower, or from the skill displayed in its cultivation.

In the nurserymen's class the flower with which Messrs. Harkness and Sons obtained the medal was a very beautiful and bright bloom of Horace Vernet, exhibited in the style in which Messrs. Harkness generally manage to show this Rose; what a pity it is that it can hardly ever be shown from anything but maiden plants. There was also a very beautiful bloom of Madame Cusin which obtained for Mr. B. R. Cant the medal for the best Tea or Noisette. Several flowers were exhibited as seedlings, and, as usual of late years, Messrs. A. Dickson & Sons of Newtownards carried off the gold medal for Ulster, another of their series of beautiful pink Roses, of which Mrs. Kellar and Mrs. Sharman Crawford are good instances. It is a flower of great substance and depth of petal, fragrant as all medal Roses ought to be, and very vigorous in growth, with smooth wood and bright glossy green foliage. There were several other Roses exhibited in this class, of which Mrs. Rumsey, exhibited by Mr. C. Rumsey, a pretty garden Rose, and Royal Scarlet, a brilliant coloured flower, exhibited by Messrs. Paul & Son, obtained cards of commendation; they also exhibited the Rev. Alan Cheales, a flower of peculiar shade of colour and very vigorous in growth. Messrs. Dickson & Son had Countess of Caledon and Killarney, both likely to be useful Roses. Messrs. Frank Cant and Co.'s Mrs. Frank Cant is another very promising flower of which I think we shall hear more by-and-by.

Men and Meetings.

I have already alluded to the change in the *personnel* of exhibitors. I may also notice another change. Mr. Orpen has moved a step higher, and Mr. Charles Grahame has occupied, as I was sure he would do, a very leading position, and I have very little doubt that his success this year is a precursor of still greater successes in the years to come; and it would be ungracious to leave any notice of the Metropolitan Show without saying how much the Society is indebted to him for his generosity, and also for the trouble which he has taken in procuring the very appropriate and beautiful silver trophy in the amateurs' division.

There is one feature of the Metropolitan Show which always gives to it an additional interest—viz., that it affords a meeting place for rosarians from all parts of the country. It is pleasant to meet old friends and to be able to take counsel with them on the various merits of the flowers we love. Whatever they may do on other occasions, they always try to be at the Crystal Palace. Of course it has its painful side, for there are many blanks, and we miss every year one or more of those who used formerly to be with us. One is especially glad to see that Mr. Burnside, amidst tremendous difficulties, has been able to secure a first prize in his much-loved class of Teas, and I have been very pleased to hear since the show that he has once more come down into his old county, and has accepted work at St. Margaret's, at Cliffe, near Dover. I do not know whether he will be able to go in for Roses, but from what I know of him and of his zeal I think we may safely predict that he will do so. I see no lack of zeal amongst the exhibitors and friends of the Rose, and I think we may look forward hopefully to the future.—D., *Deal*.

AN AMATEUR'S GRAPES.

I note in the replies to correspondents in the *Journal of Horticulture* reference to a photograph of Grapes (Barry Dock), which I presume refers to a communication and photo I sent you a few weeks ago. This photo was taken at the time the Grapes were stoning, and as the negative was not destroyed I have had another print taken to-day, which I enclose. There are four Vines shown on the print—viz., Mrs. Pince, Muscat of Alexandria, Black Alicante, and Madresfield Court. I have had to take a berry out here and there since stoning; they are nearly all coloured now, and the Madresfield Court, which is at the further end, has the largest and best bunches.

I obtained my information on Grape culture as follows:—In the latter part of 1894 I saw growing in a small greenhouse a Black Hamburgh Vine, and from what I then observed I thought I would like to try and see what I could do myself. At this time having very little knowledge of horticulture, and no knowledge whatever on Grape culture, I was told it would take many years to understand how to grow Vines successfully; however, undismayed, I determined to make the attempt, and had a small house constructed, 15 feet by 10 feet, and made my border about 5 feet broad.

When in London I had access to the *Journal of Horticulture* for about nine years back, which I carefully looked over, and noted the dates of the weekly issues that contained information likely to be useful to me. I then called at your office and obtained all the back numbers which I had previously taken note of, and carefully read the same. I then ordered some Vines from Messrs. J. R. Pearson & Sons, and planted them. I also at the same time had two Black Hamburgh and one Madresfield Court in pots for fruiting. As the Vines did not come on so well as I expected I studied the articles in the back numbers of your Journal again, and came to the conclusion that the border was not as it should be—not sufficiently porous, so I carefully lifted the Vines, took

the whole of the border out, and made it up again with part fresh turf and plenty of lime rubbish. I then replanted the Vines in it, and afterwards treated them according to the best information from the back numbers and from articles that appeared from time to time since.

With regard to the Vines in pots, I ripened six bunches on each Black Hamburgh, and five bunches on the Madresfield Court, which did not burst any berries; in fact, the Vines in pots finished the crops very well indeed. At this time the Vines in the border had completed their growth, and were stopped at 9 feet, then kept in check. The canes at this time were a good size, with prominent buds. When the leaves were down they were pruned to 8 feet, except the Muscat of Alexandria, which was pruned to 6 feet 6 inches. The following year (last year) the Madresfield Court carried six bunches, Black Alicante three, Muscat of Alexandria four, and Mrs. Pince five. These finished well, and the canes were stopped at 12 feet, and afterwards pruned to 11 feet, except the Muscat of Alexandria, which was pruned to 9 feet.

I started the Vines about the middle of February, and they soon began to show plenty of bunches. I left nine on Madresfield Court, nine on Alicante, six on Muscat of Alexandria, and eight on Mrs. Pince, which you will see by the photo look fairly well considering the prevalence of dull, cold, and wet weather during the whole of the time the Vines were in flower. At the present time the Madresfield Court is nearly all coloured, and promises well to make a good finish, the weight of the bunches ranging from 2 to 3 lbs. By carefully following the instructions given in the *Journal of Horticulture* on the treatment of Madresfield Court I have not had a cracked berry this year, neither have I had any trouble from this cause the two previous years.

Up to the present time I have had no gardener to advise me or assist me in any way, and I can assure you I am most anxious to obtain your Journal every Thursday as early as possible. I may add that my Vines are grown in an inside border with a brick wall above the border, so that the lower part of the Vines are below the staging.—THOS. LOWDON.

[We have pleasure in publishing the foregoing narrative, and those of our contributors of information on Vine culture will be gratified by the results, as shown in the photograph, taken, it may be noted, "when the Grapes were stoning." The photograph was in our hands some weeks ago, but as the explanatory notes were not so full as we desired, and as Mr. Lowdon's address was not quite clear either, we inserted a reference in our "correspondents'" columns with the object of eliciting the information now imparted by the grower of the Grapes represented in fig. 15. Judging by the photograph, the results seem to be altogether creditable. That the Vines were good goes without saying, and that their cultivation has been good appears to be equally conclusive.

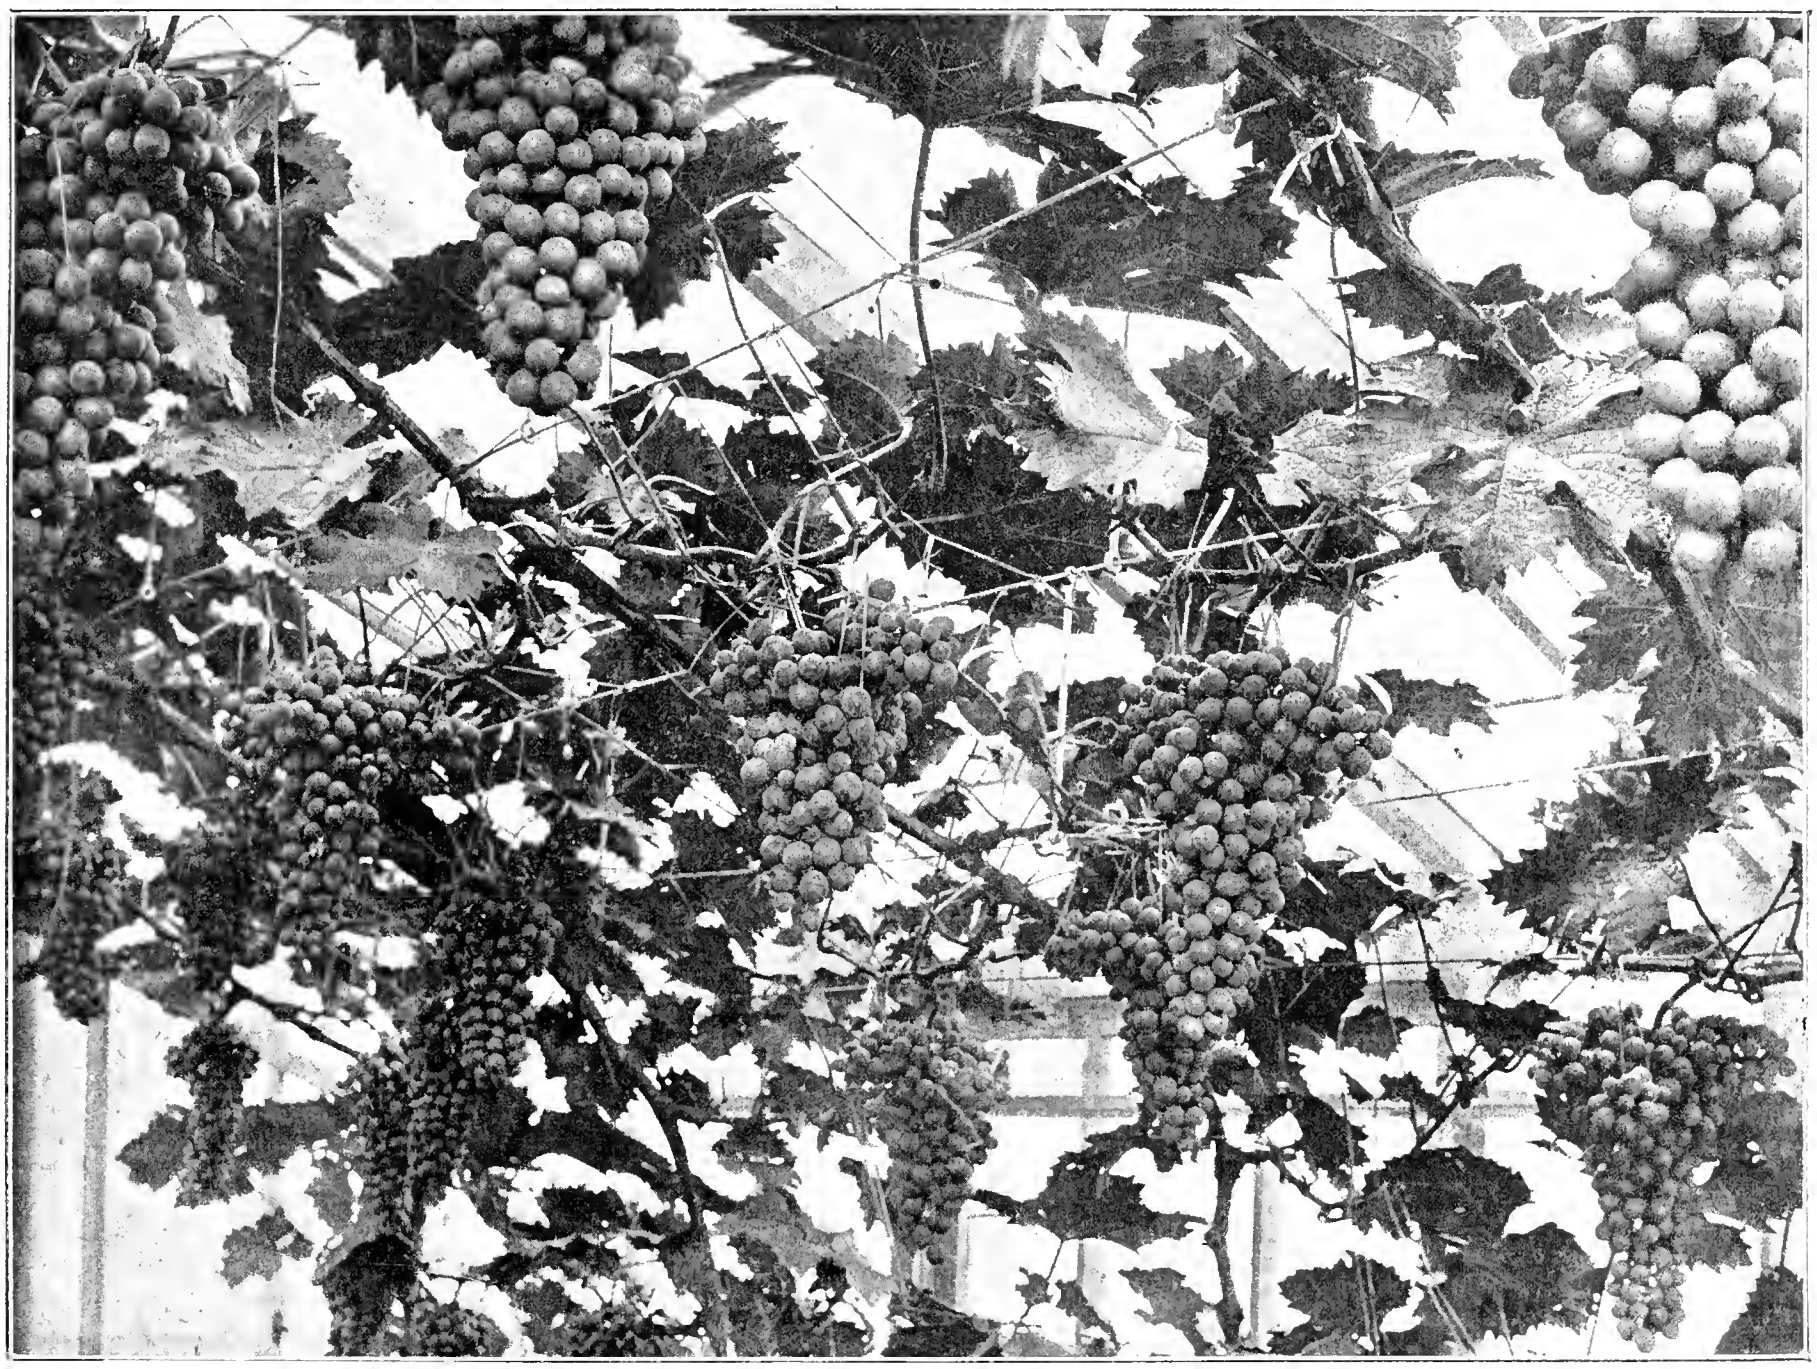

FIG. 15.—AN AMATEUR'S GRAPES.

We have two or three observations to make on this instance of success in Grape growing. 1, The same information which Mr. Lowdon turned to such good account must have been read by thousands more and some we may hope have equally benefited by it. 2, If there is a horticultural society in the district, and if, say, three sound gardeners were delegated to inspect the Vines in question, and they were found to be all that the photograph suggests, might they not, under all the circumstances of the case, be deemed worthy of some official recognition?

This opens another question—namely, Would it not be appropriate for societies, which are established for the promotion of local horticulture, to go beyond the show tent now and then and recognise exceptional merit in cultivation where this is in a form that cannot be "exhibited," though not the less meritorious, as in the case of a house of Grapes? What say our readers on the extension of the usefulness of such societies on the lines suggested by the Grapes of Mr. Lowdon, who sends us his address—23, Kingsland Crescent, Barry Dock. In the meantime we ask his acceptance of our congratulations.]

NANODES MEDUSÆ.

THOUGH lacking the delicate beauty of many Orchids this species possesses in a marked degree the quaint grotesque character that go far to make the family so popular, and anyone who delights in these singular and marvellous productions of Nature could not do better than include a plant or two in his collection. Some botanists have ascribed this and the other species in the genus to Epidendrum, as to this genus the structure of the blossoms bears a great resemblance. The habit is, however, so distinct that as a garden plant it will doubtless continue to be known by the name Dr. Lindley gave it from the typical N. discolor.

It is by no means a rare plant, yet not so frequently seen as it deserves. Its culture is not difficult if only it is allowed to have its own way, and cultivators do not try to force it into a resting and growing season according to their own notions of how it should grow. Watch the plants, and note how before one growth is finished another starts away, and how little rest it requires will soon be apparent. Keep it in a moist and mild temperature the whole season through, and never allow the roots to become absolutely dry. These may be accommodated in pots, pans, or baskets, but are best in every case suspended from the roof.

Tree Fern stems, too, form a capital holding for the roots, the open nature of this material, combined with its power of retaining moisture in just the right quantity, rendering it perhaps the very best material that could be used. If grown in pots or baskets the plants should not be disturbed more than is absolutely necessary, so when the time comes for a renewal of compost the work should be thoroughly done. The latter may consist of two parts of sphagnum moss to one each of the best peat fibre and broken crocks, this making a medium that will not readily lose its proper mechanical condition on the one hand yet hold plenty of moisture.

The flowers occur at the end of the stiff ungainly-looking shoots, and vary a little in colour. The usual tint is a brownish yellow on the sepals and petals, the lips roughly heart-shaped, magenta purple in front, where it is cut into deep filaments, as seen in Dendrobium Brymerianum. They occur at different times of the year, sometimes in pairs, but more often singly, and last a long time in perfect condition if not wetted with the syringe. To Messrs. Backhouse of York the credit of its introduction is due, this firm having first imported it from Ecuador as far back as 1867.

BOLLEA CŒLESTIS.

This is one of the very best species in the genus, and an unusual colour in Orchids. The plant has no pseudo-bulbs, the growth consisting of more or less erect stems from a rather tufted rootstock, young roots being annually produced from the base of these. The flowers occur in single-flowered stems over a foot in height, each measuring from 3 inches to 4 inches across. The sepals and petals are a pretty light blue at the base, becoming nearly white at the tips, the lip large and deep violet purple.

Many growers make the mistake of giving this and similar Orchids much too thick a compost, the roots in many cases perishing before they can get through it. About an inch or a little more is ample for small or medium specimens, a little more being allowed for large plants. Fine specimens have also been reared on pieces of Tree Fern stems, a capital holding for them if these can be obtained. But whatever is chosen for their reception, it is imperative that they be very firmly fixed in position, so that they cannot possibly ruck about.

The compost for baskets or pots may consist of peat and sphagnum—care being taken to have the latter quite fresh and clean—with plenty of rough lumps of charcoal. Remove the whole of the old material from the roots, and if these are in bad condition let them dry thoroughly before replanting, and cut out all dead and decaying ones. The new tiers have then the advantage of new, sweet compost.

There is no need to elevate the plants above the rims if potted, but neither should they be much below, as in this case moisture is apt to collect about the rootstocks to an injurious extent. Work the new compost about the roots with a fine-pointed dibber, and make it fairly firm. After potting place the plants in their growing quarters with as little delay as possible, and water very carefully until the roots are again active. When these are getting well about the new material a full supply will be needed right through the growing season.

In winter of course less will be required, as owing to the atmospheric conditions outside the roots do not dry so rapidly. But no dry rest is needed—simply a reduction of moisture as in any ordinary plant to meet the exigencies of the weather. These ebulbous kinds are not, if judiciously managed, very subject to insects, but on the other hand, if once badly attacked, they are more easily injured. Hence the necessity for very rigid exclusion of these pests as scale or red spider, sponging or using the vapourising fumigator directly the first insects are seen.—H. R. R.

MUSTARD AND CRESS FOR MARKET.

[The following article was written some years ago by Mr. Lewis Castle and published in the *Journal of Horticulture*, but as the issue containing it is out of print, the article is reproduced by desire of three correspondents whose letters are before us, and it will doubtless be acceptable to many of our readers.]

IN most English gardens attention is given to providing a supply of Mustard and Cress for salads, and being easily and quickly grown, and further possessing very wholesome qualities, they are within the reach of all, even to those with most limited means or accommodation for plant or vegetable growing. Still, very few residents at a distance from London have any idea of the extremely large quantities of this small salading grown to supply the demands of the metropolitan markets. It is only by visiting the gardens where its culture is made a speciality, or by an early morning journey to Covent Garden Market, that anyone unacquainted with the facts would be able to form the slightest conception of the extent of the trade in such apparently insignificant productions. One reason for this is that Mustard and Cress require to be quickly grown, quickly sold, and quickly conveyed to the consumer, as they soon become tough and tasteless after cutting; and the consequence is that outside the markets large quantities are seldom seen, as the retailers purchase only what is ordered, or as much as they consider will meet the demand for the day. The supply is thus very generally distributed, and though few shops have more than a dozen punnets, there is scarcely one in a respectable neighbourhood that does not require some daily. But for this fact it would seem almost incredible that so large a quantity as some growers raise could be consumed while fresh.

The chief season for Mustard and Cress is during the spring months, at which time a thousand dozen punnets are brought to Covent Garden Market daily by the chief growers, and one alone sends from a thousand to fifteen hundred dozen punnets per week. The supply is maintained in a varying degree throughout the year, reaching its lowest in November, December, and January, especially in severe or very wet seasons. It is, however, a constant crop, and one grower informs me that his supply would average five hundred dozen punnets per week throughout the year; and judging by the space he devotes to its culture the quantity does not seem to be exaggerated, though the results are somewhat astonishing when we consider the money value that is realised.

The price per dozen punnets varies from 1s. to 2s.; but as less than the first-named price has sometimes to be taken the average might be fairly considered to be 1s. the dozen. Thus five hundred dozen per week would give a total annual amount of £1300; and taking the profits at the very low estimate of 10 per cent. we have a yearly income of £130 for Mustard and Cress alone. From what I have seen and can judge of the labour and expense incurred in the production I should, however, think the profits would be nearer 20 than 10 per cent. The result appears almost incredible, and considering that even those market gardeners who grow the largest quantity of small salad also have several other crops, especial attention being paid to Mushrooms, this form of market gardening seems to be a rather satisfactory one. It must be remembered that these particulars only refer to those who grow the largest quantities, and less than half a dozen almost entirely supply the demands of Covent Garden. In small quantities it would probably not pay for carriage, and most of those mentioned as making a speciality of small salading have wagons which convey that and other produce to London and return laden with manure. The grower must also be conveniently situated as regards distance from the chief markets, or the expense would be considerably increased and the quality of the salad greatly deteriorated if it remained closely packed for too long a time.

It may be of interest to some readers to know the methods of growing this salad adopted by market gardeners around London, and as I have recently had an opportunity of visiting several of these establishments a few observations upon the subject will give an idea to those who are desirous of commencing the culture on a large scale. It may be premised that though some of the best gardening in the kingdom is to be seen in market growers' establishments, yet there is generally so much trade rivalry and jealousy that a reluctance to communicate any details of culture very generally prevails. Some who have been successful imagine they possess a secret essential to the satisfactory production of any particular crop; yet after all they only act upon general principles, and in half-a-dozen different establishments as many different systems may be seen in operation, with results that vary but very slightly, and are in a pecuniary point of view equally satisfactory. So it is with the crop now under consideration. One man who has been very successful in the culture of Mustard and Cress, and who sends a very large quantity to market, considers that his progress is due to certain cultural details which he would not communicate on any con-

sideration, and he is under the impression that other growers are continually endeavouring to ascertain these, even going so far as to offer some of his men very high wages to obtain their services; yet this does not appear necessary, for all growers I have seen have equally good crops.

One highly important matter is to obtain good seed, as unless this is done the crops will come irregularly, and it will be difficult to obtain a constant, reliable supply. It may be here mentioned that very little of the true Mustard (Sinapis alba) is grown, the substitute employed being Rape (Brassica rapa), which is preferred chiefly because it has a milder flavour, and the young stems blanch very readily, being also free from the small hairs which the stems of Mustard bear. Cress (Lepidium sativum) is grown in less quantities than the Rape, as it is less in demand, and, further, it is rather more trouble to raise than the other, as most gardeners know. The wholesale prices per bushel average about 12s. for Rape and Mustard and 16s. for Cress, though samples of superior quality realise higher prices.

Another point that especially needs attention is sowing the seed very thickly (in the case of the Rape the seeds are placed as closely as possible), as that not only insures the blanching of the stems, which adds greatly to the value of the crop, but it also simplifies the packing, as when the stems are so close together they are cut and placed in the punnets quickly and evenly. A light soil or compost is invariably employed; but the best results appear to have been produced by old Mushroom-bed manure not too much decomposed, which is sifted or screened and placed in beds 3 or 4 inches deep quite level, moderately firmly, and if at all dry it is thoroughly watered before sowing the seed. Almost any kind of light soil is suitable, and old tan was used at one time very largely for the purpose; indeed, there was one grower at Vauxhall some years ago who employed that entirely. It is also said that the sawdust which is now used in some stables is well adapted for Mustard and Cress; but it is too "strong" when first received from the stables, and requires storing for a time or to be drenched with water to remove some of the ammoniacal compounds with which it is saturated. An important object is to obtain salad free from grit, and on this account the old Mushroom-bed manure seems to be especially useful, as it forms a moist nourishing medium, in in which the rootlets can readily extend. The seed not being covered with soil also aids in insuring a clean crop, and the surface being rendered as fine and even as possible, the produce is obtained of equal height, which also adds considerably to the value of the crop, and facilitates the cutting and packing in punnets.

These particulars especially apply to the winter and early spring supply, which has to be raised in heated houses or frames. In the summer beds are prepared outside. Where the early supply receives much attention small span-roof houses or lean-to frames are devoted entirely to the purpose, as are the inside borders of late vineries. In the former case the houses are about 9 feet wide and 6 feet high, and vary in length from 30 to 60 feet, but of course the length is of little importance. They are heated with 2-inch or 2½-inch pipes, one row extending round near the sides. The beds are 4 feet wide, thus leaving a space of a foot for a path down the centre, which are edged with narrow boards 3 or 4 inches deep on each side, and next to the pipes also. The frames are about 5 feet wide, with a pipe along the front. In the case of the vineries the prepared soil is simply spread on the surface of the border to the required depth, and the seed is sown, sometimes being pressed slightly into the soil with a flat piece of wood or something similar. A good supply of water is then given, and the seed is covered with ordinary garden mats. These are only removed when it is necessary to supply water; and this must be carefully attended to, as little is given after germination is well advanced, or decay is likely to result. The mats are kept on during the day until the young plants have grown an inch or two, when they are removed to permit the seed leaves to acquire a bright green colour—a point of some importance in combination with well-blanched stems.

In from eight to twelve days the crop is ready for cutting—*i.e.*, when the stems are about 4 inches high, and to effect this a peculiar but simple knife is used. This has a straight flat blade like an ordinary dinner knife, but not rounded at the end, about an inch broad and a foot long. Near the handle is a crank turned upwards at right angles to the blade like a bricklayer's trowel, and the end is again turned at right angles, but parallel with and away from the blade; this is inserted in the handle just like the trowel. With this instrument the salad is cut much in the same style as mowing with a scythe, the blade being flat on the ground. One sweep of the knife cuts enough or more for a punnet, and is taken up with the hands and placed in evenly, so that it appears almost as if it had grown in it. Some practice is required to effect this satisfactorily, and skilful, experienced cutters can gather and pack over a thousand punnets a day. The punnets are then packed in boxes and conveyed to market in vans. The chief labour is removing the old material from the beds, which has to be done after every crop; this is stored away in a heap for several months and then incorporated with fresh material. Where the compost is purchased this is a rather expensive item, and one grower, I am informed, pays 2s. 6d. a load for old Mushroom-bed manure. In the best managed establishments, however, Mushrooms are grown in addition, and that outlay is thus to some extent reduced. It should further be added that both houses and frames are constructed in the most economical manner possible, utility and cheapness being the chief objects.

As to space required, some idea may be gathered from the fact that the punnets are about 6 inches in dimater, and I should think at a safe estimate a square foot of a good crop would fill two punnets of Rape, a little more Cress being required. Thus a heated frame 60 feet long with a bed 5 feet wide would yield about fifty dozen every fourteen days throughout the year, as the lights could be removed and the heat discontinued as the season advanced. Taking twenty-five crops in the year at the rate of 1s. per dozen would give a yearly total from one frame of £62 10s.; or, to put it in another way, the yearly return per square yard of ground occupied would be over £1 10s., a quarter of an acre so cropped giving £1815 per annum.

Although Mustard and Cress seed differ in cost to the extent of 4s. per bushel, there is not much difference in the results to the grower. For instance, a bushel of Mustard or Rape is sufficient to sow 256 square feet of bed, the same quantity of Cress being sufficient for 384 square feet; but for the same cost as the Cress 340 feet can be sown with Mustard. The ultimate results thus vary slightly, for though a somewhat higher price is obtained for the Cress, yet smaller quantities are required, and there is more uncertainty regarding the crop. As a guide to those intending to grow this salading it may be stated that a pint of Mustard seed is required for each 4 square feet, and the same amount of Cress for each 6 square feet. From about 25 to 30 per cent. should be deducted from the estimated returns for the cost of the seed. Thus, to provide the five hundred dozen per week mentioned above, between six and seven hundred bushels of seed are used yearly, at a cost of something over £400, or about one-third of the returns. The punnets are very cheap, but even for them, where such large quantities are grown, £2 or £3 per week is said to be the average outlay. It should be stated that some growers soak the Rape seed in water before sowing to hasten the germination.

Such are a few particulars concerning a very simple crop, which, if judiciously managed, can evidently be made more profitable than some others apparently of far more importance. The prices and quantities have been chiefly furnished by reliable market salesmen, and the information obtained from several different sources agrees in the main facts. Further, to avoid misleading statements as much as possible, the lowest figures have been given in each case.

TUBEROUS BEGONIAS.

THE display that can be made with a collection of these beautiful flowers is a magnificent one if the colours are carefully selected, and both double and single flowers are grown. But it is a matter of no small trouble to make a selection, especially if plants are desired for cultivation in the border as well as in the greenhouse, for some that succeed admirably in the latter are unsatisfactory in the former, and *vice versâ*. Then there are several that produce a fine effect when placed in baskets, and for this purpose particularly tuberous-rooted Begonias are not nearly sufficiently grown considering the results that may be achieved at so little cost of both time and money.

Many kinds of plants, upon the cultivation of which a considerable amount of time must be expended so as to achieve satisfactory results, are grown in large quantities, while tuberous-rooted Begonias are neglected. Not that this is the case to-day—or at any rate not to such an extent as a few years ago. Still, the fact remains that they are not accorded the attention to which their several merits undoubtedly entitle them. But if our large growers continue to put improved varieties on the market it may be naturally expected that ere long they will be grown all over the country, both in large and small gardens, for it must be remembered that they are equally well adapted for either. Under glass or out of doors, in the midst of towns or in the heart of the country, they grow well, and will give the maximum of display with the minimum of trouble.

To thoroughly appreciate the beauty of the foliage and of the flowers under either system of culture a place must be visited where a large collection is cultivated, such, for example, as that of Messrs. J. Laing & Sons, Forest Hill. Here may be seen in the houses and in the open ground thousands of plants in all stages of growth, and it is impossible for anyone to see them without having a wish arise to grow some. Not only is there great variation in the colour, shape, and substance of the flowers, but the leafage also is wonderfully diversified. On one plant the leaves may be green, while in another they approach the Rex varieties in their splendid marblings. Then there are the single flowers with smooth edges and with fimbriated ones, similar variations prevailing amongst the scores of doubles, while the habits of the plants are scarcely less dissimilar. Taking all these things into consideration it cannot be a matter for surprise that the popularity of the tuberous Begonias becomes greater year by year.

In view of the fact that many readers of the *Journal of Horticulture* are interested in these plants, a recent visit was paid to the Forest Hill emporium to see a few of the best varieties in flower. The "few" mounted to many scores, but notice was only taken of some of the new ones amongst the doubles and the singles, of each of which mention will be briefly made. Taking first of all the doubles, we will commence with a striking orange scarlet variety that has been named Dr. Jim, and which is superb. The upstanding soft salmon blooms of Duchess of Marlborough are singularly beautiful, as are those of Lady Pearson. The colour of this variety is apricot tinged with buff, making a very charming flower. The large crimson blooms of Li Hung Chang ought to make the variety an effective one for exhibition purposes. Very beautiful are the crimson of the Hon. Cecil Rhodes, the pure yellow of Diamond Jubilee, and the cerise of Lady Rosmead.

Though most people give the preference to the double varieties as making the best display, the single ones are very beautiful and, moreover, very effective when carefully staged. Evidence of this has

frequently been seen at many of our large shows. The bright pink of Marchioness of Northampton is very pleasing, as is the yellow of Mrs. Faudel Phillips. The habit of both of these is excellent. If one of delicate colour be desired there is Countess Nelson, while in direct contrast is the crimson Earl Brownlow. Mrs. Crisp, cerise, and Dr. Nansen, soft scarlet, are both varieties of merit. Half a dozen new ones have been mentioned, but there are many others of equal merit which must be omitted.

Hitherto note has only been made of those that are especially adapted to culture in pots, but it would be unfair to omit mention of a few of those that are admirably suited for bedding purposes. Amongst these are Duke of York, of which the colour is rose with a lighter centre; Jules Sacy, orange; Source d'Or, yellow; Phosphorescens, rich deep crimson; Golden Ball, yellow, and Madame E. Tourtell, white.—WANDERER.

THE BRADFORD PUBLIC PARKS.

THE smoky town of Bradford can boast of several public parks, which have been designed with skill and taste, and are well kept, this being the more praiseworthy under an atmosphere laden with smoke from hundreds of factory chimneys. Bowling Park, which is 53 acres in extent, with its flower garden, terrace, broad and undulating lawns; its clumps and belts of shrubbery; its vistas and lakes—all betoken skill in formation and care and management. On the western side are several acres of woodland. Overlooking the park on the east is Bolling Hall, formerly the seat of the De Bollings and Tempests of knightly fame. Built more than 500 years ago, it stands to-day unchanged as in those ancient days, with its latticed windows, its banqueting hall with raised daïs and minstrels' gallery.

The conservatory in the public park is at all times of the year filled with bloom. It is a lofty structure of about 90 feet by 30 feet. Two-thirds of the space is occupied for the display of flowers, the other part as a stove. The central portion of the flowering house was arranged with large Camellias, several plants of Kentia Fosteriana, Ficus elastica variegata, and Araucaria excelsa. In the foreground was a large bank of bloom, perfect in freshness and beauty, composed of good plants, in 6 and 7-inch pots, of double and single Zonal Pelargoniums, double Petunias (purple and white), Show and Fancy Pelargoniums, Schizanthus pinnatus, Spiræas, Hybrid Perpetual Roses, and Lilium auratum interspersed throughout the group. The edging was of Spiræas, Anthericum variegatum, and Aspidistras. The side stages were filled with all the above-mentioned flowering plants, with the addition of some fine pots of Machet Mignonette, and were edged back and front with blue Lobelia and Harrison's Musk.

The arrangement of show houses in public parks must be effective as seen from the exterior as well as the interior. The rafters were clothed with Cobœa scandens variegata, and profusely flowered Heliotrope. Hanging from the roof were wire baskets, 8 inches in diameter, filled with blue Lobelia and Harrison's Musk (but not in mixture), a fault which is not perpetrated here. There were also several large baskets of single Petunias in self colours. The other baskets were one of Stenochlæna scandens, one of Cyrtodeira metallica, one of Nephrolepis tuberosa, and several of Asparagus decumbens.

In the stove portion everything betokened cleanliness and good culture. The centre was arranged with several large Areca lutescens and Cocos flexuosa, while around the sides were Crotons, Dracænas, Dieffenbachias, and Caladiums, edged front and back with Caladium bicolor and C. argyrites. Amongst noteworthy objects in this house were several fine pans of Cyrtodeira metallica and Selaginella apoda, also a plant of Schubertia grandiflora covered with its fragrant white flowers. The rafters were clothed with Allamandas and Gloriosa superba. In this house a hanging basket of Hoya bella, profusely flowered, was very attractive; Davallias grown on cork rafts, and several Orchids in teak wood baskets were noticeable.

Mr. Spencer, the superintendent, is well known in the neighbourhood as an excellent gardener. All the parks, besides these show houses, have adequate glass for the growing and propagation of the plants for the flower gardens and conservatories.

Peel Park, purchased in 1853, cost, with laying out, £12,000; it is 53 acres in extent. For the whole length of the park the ground slopes in a gentle declivity. On the southern rising ground is a terrace 30 feet in breadth and at least half a mile in length, sheltered by trees and shrubs. On each side of its entire length are grassy recesses, flower beds, and statuary. The conservatory, a lofty structure, 100 feet by 30 feet, was arranged on the ground without any side stages. In the centre was a large Dicksonia antarctica, Camellias, and Phormium tenax, backed up with flowering plants, consisting of large Fuchsias, Zonal Pelargoniums, silver-edged Zonal Pelargoniums (large plants) Spiræas, Lilium auratum, and L. Harrisi.

Horton Park, opened in 1878, is 39 acres in extent from west to east, and the park has a gentle slope. The terrace runs in this direction. On one side of the terrace are eight sheets of water connected by miniature waterfalls, the banks on the northern side being clothed with trees, shrubs, and Ferns to the water's edge; grassy banks slope down from the terrace to the lakes. The lofty conservatory, the flowering part, 60 feet by 30 feet, had a central arrangement of Camellias, Araucaria excelsa, and A. Bidwilli. The bank of flowers was composed of about a dozen large Genistas, Lilium auratum, L. Harrisi, Schizanthus pinnatus, Spiræas, Fuchsias, Zonal Pelargoniums, Show and Fancy Pelargoniums. Amongst the latter were several good plants of the pure white Duchess of Teck. The side stages had smaller plants of the above, with the addition of Rhodanthe Manglesi, Eulalia japonica variegata and E. japonica zebrina, Coleus, Primula obconica, Hydrangea hortensis, and H. Thomas Hogg. The stages back and front were edged with white Lobelia, and a pale blue and white Lobelia, similar to the old Paxtoni, Harrison's Musk, and Isolepis gracilis. The stove had the usual fine-foliage plants, with the addition in the way of flowers of Gloxinias and Clerodendron fallax.

Lister Park, 54 acres in extent, was purchased in 1870 from the Cunliffe-Lister family, who were seated at Manningham House in the park for several centuries. It was bought for £40,000, and cost £10,000 to lay out. In this park are the monuments of two men who have more than any others developed the trade of Bradford—namely, Samuel Cunliffe-Lister, now Lord Masham, and Sir Titus Salt, Bart., of Saltaire; the latter monument, of white Carrara marble, formerly stood near the Town Hall.

There are in this park three conservatories in a line. The central one is 20 feet high, 100 feet long, and 30 feet in breadth. It was arranged with Camellias, a large Dicksonia antarctica, and several Dicksonia squarrosa, a Chamærops Fortunei, and Chamærops excelsa, with Phormium tenax and Japanese Maples. The flowering plants were Spiræas, Fuchsias, and Zonal Pelargoniums. The side stages had hundreds of herbaceous Calceolarias in bloom, Spiræas, Zonal Pelargoniums, and Fuchsias edged with common Musk and Isolepis gracilis. On one side of this central house is a stove, on the other a greenhouse, each about 90 feet long, besides the other preparatory houses. In addition to the aforementioned parks is Bradford Moor Park, of smaller extent, but equally well kept.—F. STREET.

BIRMINGHAM GARDENERS' ASSOCIATION.

UPWARDS of eighty members and friends enjoyed the annual outing on the 21st inst., by the kind permission of the Earl of Rosebery and Leopold de Rothschild, Esq., to Mentmore and Ascott. The weather proved most auspicious, though distant thunder was heard in the afternoon, accompanied by a few drops of rain when the party was at Ascott in the afternoon.

Upon the arrival at Leighton, about 10.30 A.M., the party was conveyed in brakes to Mentmore, viâ Cheddington. One of the most marked features during the route were the several large orchards of Damson trees, both old and young, the variety being apparently the Prune. Walnuts, however, appeared to be a good crop. The ride up the long carriage drive leading to the mansion, or rather the village of Mentmore, proved very interesting to those fond of tree scenery. There were several groups of fine Wellingtonias on each side of the drive. Mr. J. Smith, the well known head gardener, met the visitors at the entrance to the gardens, and at once conducted them through the glass department. The large house of Muscat of Alexandria revealed a crop of extraordinarily fine bunches with large berries on the eve of perfect maturation, as they were assuming the desirable amber tint. The other crops of Grapes were also in capital form. The fruit of Peaches and Nectarines in a large house had been gathered. The houses containing large quantities of stove and greenhouse plants also elicited admiration.

The *pièce de resistance*, however, was the palatial looking mansion with its splendid and extensive grounds and arboreal surroundings, coupled with the magnificent view of the Vale of Aylesbury and the distant Chiltern Hills. The mansion and pleasure grounds, which were designed in 1851 by Sir Joseph Paxton, are indeed lasting monuments of his genius and capability both as a landscape gardener and an architect. It is needless to remark that good order and neatness abounded, though on the previous day the heavy storm of rain had left evidences of its character on the sides of the sloping walks. Altogether the visitors were delighted with what they saw.

Heartily thanking Mr. Smith for his courtesy and attention, the visitors, about two o'clock, "made tracks" for Ascott, a distance of nearly three miles, where they were met by Mr. John Jennings, the head gardener, who led the way through the extensive and charming grounds, which are of varied beauty and picturesqueness. The Elizabethan mansion of brick and timber is partly clad with Wistarias, Roses, Clematis, and other trailing and climbing plants. A leading feature in the extensive shrubberies was a profusion of golden-hued trees and shrubs, planted in large masses and singly, in great variety, and which, well balanced with a rich and varied assortment of other subjects, including an extensive accompaniment of hardy herbaceous flowers, ornamental foliaged plants, besides the parterres of "bedding out" flowers, the whole constituting a picture of no ordinary splendour.

Sharing the admiration of the visitors was the large and splendid array of Carnations contained in the glass structures, principally of such varieties as Souvenir de la Malmaison, Mrs. Leopold de Rothschild—a most fragrant and beautiful pink-tinted variety; also the bright pink variety Princess of Wales, a great favourite at Ascott, both of which, with Mr. Arthur Sassoon, the best yellow self, James O'Brien, a beautiful scarlet, and others too numerous to mention, form one of the glories of the place.

Having thus feasted their visual and olfactory organs, the visitors were in readiness for the refreshing and excellent "meat tea" laid out in the cricket pavilion through the considerate generosity of Mr. Leopold de Rothschild, and, as may be readily guessed, the abundant accompaniment of "Strawberries and cream" afforded an additional delectation to the palates of the gratified visitors. A visit to the extensive and

well-kept stables, also the electric machinery department for producing light for the establishment, and other works, was also much appreciated by the visitors.

At the conclusion of the tea a hearty vote of thanks was sent by telegram to Mr. Rothschild in acknowledgment of his kindness and hospitality, also an equally hearty one was accorded to Mr. Jennings for his courtesy and untiring attention. Altogether the day's outing can be regarded as a red-letter one in the annals of the Society.—W. G.

BORONIA POLYGALIFOLIA.

THOUGH many of the Boronias are largely cultivated, this one (fig. 16) is very seldom seen, though it is one of the most useful of the genus. Wherever it has been fairly tried, the highest opinion is held of its merits as a greenhouse or conservatory plant. During the spring and early summer months plants are quite masses of flowers. These are borne on corymbose heads, are of a bright rosy-lilac hue, and last a considerable time either upon the plant or when cut. The growth being very free, the plant will endure hard cutting, a valuable quality in these days when flowers are so largely in demand; and though the colour is not so brilliant or startling as that of some plants, it is a shade that can be readily associated with many others without producing any unpleasant discord. It requires similar treatment to other species of the genus.

COLOUR IN WILD FLOWERS.

As we walk through the fields, the country lanes, and the woods in spring, summer, and autumn, and notice the variety of colour in the wild flowers, the question very often arises in our minds, "What is the commonest colour?" We see fields a perfect blaze of yellow Buttercups, a waving sea of Ox-eye Daisies or a gorgeous carpet of purple Clover, the hedges pink and white with wild Roses varied by the white cymes of the Elder, the green and white of the Guelder Rose, and the pink, yellow, and white of the Woodbine, the banks gay with the pink of the wild Geranium, the white stars of the Stitchwort and the "darling blue" of the Speedwell, and the paths by the roadside thickly matted with the grey leaves and golden cups of the Silverweed.

In the natural order Compositæ, which contains the largest number of genera, out of forty-five different species twenty-five are yellow, nine purple, six white, and two blue, the Chicory or Succory and the Cornflower or Bluebottle. In the next largest order, Umbelliferæ, out of thirty-six species twenty-four are white, three yellow, one (the Sea Holly) blue, and the remainder greenish or pinky white.

In the Cruciferæ out of twenty-six species we find fourteen white, seven yellow, one (the Cuckoo Flower or Lady's Smock) lilac, and the Hedge Mustard, "Jack-in-the-Hedge," white and yellow. Dyer's Woad, now seldom found, is yellow. In the Labiatæ the colours vary very much; white Dead Nettle, yellow Archangel, lilac Mints, purple Thyme and Betony, rose Hemp Nettle, blue Skull-cap, and violet Prunella or Self-heal.

In the Rosaceæ, which includes a great variety of plants, such as wild Roses, Plum, Cherry, Bramble, Hawthorn, Meadowsweet, Strawberry, Cinquefoil, Agrimony, Mountain Ash, Willow Herb, and Enchanter's Nightshade, we find white, yellow, pink, rose, red, purple, and one, the Isnardia, green. In the Leguminosæ, again, we find variety of colour; yellow Broom and Gorse, purple Medick or Lucerne and Clover, white Clover and Melilot, and the rose and pink of Restharrow and Sainfoin.

In the almost universal yellow of the Ranunculaceæ the gorgeous crimson of the Pheasant's Eye is very conspicuous. Poppies are brilliant in scarlet and yellow, our only other really scarlet wild flower being the little Pimpernel, or "Poor Man's Weather Glass." The wild Geraniums are mostly pink, though there is a beautiful exception in the large, bluish purple flowers of the Meadow Cranesbill. The Thistles, of which plant we have twelve species, are all purple. The common Germander Speedwell has flowers of the most perfect blue.

We have seventeen varieties of the Speedwell, and they are blue with three exceptions, the Thyme-leaved Speedwell, the Water Speedwell, and the Ivy-leaved, which are lilac. The Germander Speedwell is sometimes called the Eyebright, but the true Eyebright which grows on downs and heaths has a reddish-white flower. We get a good example of a lilac family in the Mints. While the Scorpion Grasses are all blue—and there are eight of them, the best known being the Water Scorpion Grass or Forget-me-not—one of them, the versicolor, is a yellowish blue.

The flowers of early spring are yellow, the Celandine, Primrose, Cowslip, Daffodil, and Marsh Marigold, varied by the blue Hyacinth, white Anemone, lilac Cuckoo Flower, and purple Violet, followed a little later by the white stars of the Stitchwort, the blue eyes of the Speedwell, and the pink of the Cranesbill. The hedges are white with Blackthorn and May, the copses and plantations fresh and beautiful with the pink and white blossoms of the wild Cherry, Apple, and Pear, and the emerald green of the Larch.

Early summer delights us with wild Roses and Honeysuckle, and paints the river banks with the flaming gold of the Iris, while it spangles the waters with yellow and white Water Lilies. Later summer gives us the rich purple of the Loosestrife, the yellow of the St. John's Wort, yellow Loosestrife, Corn Marigold, Great Mullein, Toadflax, Ragwort, and a host of others, the pink of the Willow Herb, Ragged Robin, and red Campion.

Autumn's cornfields bring with them the purple Corncockle, the pale purple Field Scabious, and the scarlet of the Poppy. Spring might be painted yellow and blue and white, summer yellow and pink, and autumn purple and scarlet and gold.—("Pall Mall Gazette.")

HORTICULTURAL SHOWS.

PRESCOT.—JULY 22ND.

ON Thursday last the thirteenth annual show of the Prescot and District Horticultural Society was held in a portion of Knowsley Park, set apart by the kindness of the Right Hon. the Earl of Derby, K.G. The Park is a charming place in which to hold a show, and with an absolutely perfect day the throng of sightseers was of a very striking character, the day ending by some hundreds of people enjoying themselves by dancing on the green to the strains of the band of the 2nd S.L.V.B., under Bandmaster Hall.

Considering the precarious season the exhibits were of a high order, the groups put up by Mr. McFall, gardener to E. C. Leventon, Esq., Roby; Mr. Ogden, West Derby, and Mr. W. Lyon, gardener to A. M. Smith, Esq., Bolton Hey, Roby, for first, second, and third prizes

FIG. 16.—BORONIA POLYGALIFOLIA.

displaying much diversity, and forming a charming feature of the show. So, too, were the stove and greenhouse plants exhibited by Mr. R. Pinnington, gardener to Mrs. Banner, Blacklow House, Roby, Mr. Pinnington securing the prize for six, in which were noticeable a good Croton Queen Victoria, Cycas revoluta, Allamanda Hendersoni, and Clerodendron Balfourianum. Mr. McFall was second, his foliage plants being good. The order was reversed in class for four greenhouse plants in flower. For four Ferns Mr. Pinnington easily secured first position, Mr. Field, gardener to J. H. Wilson, Esq., Allerton, being second.

The prizes for one stove or greenhouse plant in bloom, two Liliums and six Cockscombs, were also taken by Mr. Pinnington. Mr. Lyon won with handsome tuberous Begonias, also for four Coleus. For Fuchsias, single Begonias, and Zonal Pelargoniums, Mr. E. Bridge, gardener to Mrs. Jowett, Greenhill, Huyton, staged some remarkably good specimens, taking all the prizes. The Gloxinias were excellent, Mr. W. J. Barnes, gardener to J. C. Gamble, Esq., St. Helens, taking honours.

For eighteen cut Roses, distinct, twelve distinct, and six distinct, Mr. P. Greene, gardener to Thos. Gee, Esq., Allerton, won in each class, his blooms being fine in form, colour, and effectively arranged. Mr. W. Rigby was a good second in the former, and Mr. G. Berry in the two latter with fine flowers. Mr. Greene also won with twelve fine herbaceous flowers, and Messrs. J. Appleton and McFall with double and Cactus Dahlias.

For a collection of four dishes of fruit Mr. W. Oldham, gardener to Joseph Beecham, Esq., Ewanville, Huyton, was a capital first, staging Black Hamburgh and Buckland Sweetwater Grapes, Grosse Mignonne Peaches, and good Queen Pine Apple. Mr. R. Pinnington followed. Mr. Oldham was again first for two bunches Black Hamburgh, large in bunch and berry, faultless in form, and one of the best examples of thorough culture we remember seeing. Mr. James Rose exhibited well

for second position. Mr. Oldham won easily with very fine Muscat, a little short in colour, and with small, but nicely finished Madresfield Court, Mr. James Rose following in each class. Mr. R. Pinnington secured first prizes for Peaches with Rivers' Early York, Nectarines with Violette Hâtive, Melon with The Countess, and Cherries with Governor Wood; the prizewinners for Black and Red Currants were Messrs. Oldham and Rose; White Currants, Raspberries, Strawberries, and Gooseberries, Messrs. Rose, J. Brown, and H. McFall.

In the vegetable classes the competition was good throughout. Particular mention must be made of the collection of twelve varieties, all staged by cottagers, Mr. J. Rainford winning with excellent Sutton's Autumn Mammoth Cauliflower, Snowhall Turnip, Prizetaker Leek, Moore's Cream Marrow, Perfection Tomato, Yates' Cucumber, Veitch's Model Carrot, International Potato, Canadian Wonder Bean, Stratagem Pea, Wright's White Celery and Ailsa Craig Onion. Mr. J. Pownall was a very close second, his exhibit being worthy of all praise. For collections of Potatoes, Peas, Broad and French Beans, Cauliflowers, Onions, Turnips, and Carrots, the prizewinners were Messrs. McFall, W. Oldham, W. Lyon, J. Appleton, and J. Rainford. The cottagers' section was marked by the usual high standard of excellence aimed at in former years, and formed not the least attraction of the Show.

TRENTHAM.—July 22nd.

This the ninth exhibition of the Trentham and Hanford Horticultural Society was held on Thursday last in the grounds of Trentham. These gardens have many attractions, and a more beautiful spot for holding a flower show could not be found. Of late years extensive improvements have been made, and all round gardening is carried out in a thoroughly practical manner by Mr. Peter Blair, who has had the responsible charge here for some years. The weather was gloriously fine and the show was well arranged. The quality of the exhibits was first class, and a very large company visited the show. Messrs. Alford and Jones, the Hon. Secs., are to be congratulated upon the business-like arrangement so well carried out by them and the Committee. The show was opened by the Duchess of Sutherland, accompanied by Lady Rosslyn, Marquis of Stafford, Lord H. Grosvenor, the Austrian Ambassador, and the great rosarian, the Dean of Rochester.

The principal features of the show—as is the case now almost everywhere—were the groups arranged for effect in a space of 300 square feet. There were six competitors, and the first prize was worthily awarded to Mr. C. J. Mee, of Nottingham; second, Messrs. Jenkinson & Son, Newcastle, Staffs; third, Duke of St. Albans, Bestwood, Notts; and fourth, Sir Oswald Mosely, Bart. The prizes offered for the four leading ones amounted to £70 10s., but so good were the others that the Judges felt in duty bound to make two extra awards of £5 and £3.

Roses were excellent, and amongst the best we have seen this season. For forty-eight distinct:—First, Messrs. Harkness & Son; second, Messrs. A. Dickson & Son; and third, Mr. B. R. Cant. In the class for thirty-six distinct, Messrs. Harkness & Son, A. Dickson & Son, and Townsend & Co. were the successful competitors. For twenty-four varieties, trebles, Messrs. A. Dickson & Son were first, Mr. B. Cant second, and Messrs. Perkins & Sons, Coventry, third. Twelve Teas:—First, Mr. B. Cant; second, Messrs. A. Dickson & Sons; and third, Mr. H. Merryweather. The Rev. Pemberton took first for twenty-four H.P. and twelve hardy border flowers. The chief prizes for bouquets, bridal, ballroom, buttonhole, all went to Messrs. Perkins & Sons of Coventry.

Fruit was excellent. The class for a decorated table brought forth some spirited competition. First, Mr. McIndoe; second, Mr. J. H. Goodacre, Elvaston; third, Mr. Edmund, Bestwood; and fourth, Mr. Harris, Ledbury. For a collection of six kinds of fruit Mr. McIndoe was first; Mr. Harris second; and Mr. J. H. Goodacre third. Grapes were good, but the Muscats lacked finish. The principal prizes went to fine examples grown by Mr. Reynolds, Gunnersbury House, who was first for four bunches, distinct; three bunches black, any variety; three Muscats of Alexandria; three white, any other kind; two bunches black, one white, the other prizes going to W. D. Drury Lowe, Esq., and Mr. McIndoe. Peaches, Pines, Melons well shown.

Vegetables were splendid. We are doubtful if a finer lot at this season of the year has been seen, especially those shown for the valuable prizes offered by Messrs. Sutton & Sons, the successful exhibitor being Mr. Wilkins, gardener to Lady Theodore Guest, who also took Carter's special prize.

BROOKFIELD.—July 24th.

The thirteenth annual exhibition of the Brookfield Horticultural Society took place at South Highgate, in a field kindly lent for the occasion by W. Burdett-Coutts, Esq., M.P. The object of the Society is to encourage the growth of fruit, flowers and vegetables in the Brookfield Allotment Gardens, and in the cottage gardens of the working classes resident within the district of the Society.

The show was a decided improvement on former years, the number of entries reaching nearly 800, being fifty in excess of the average. Prizes to the value of 35 guineas were offered for cottage gardens, window gardens, plants and cut flowers, and other garden produce. All the classes in the schedule were well filled, the exhibits being remarkably good, comparing well with the produce from a gentleman's garden.

For the allotments, of which there are upwards of fifty plots, each averaging about 10 poles, and each having a strip of flower border on the frontage, twelve prizes are given by the Baroness Burdett-Coutts for the vegetable gardens, and the same number by B. G. Elliott, Esq., Hon. Sec., for the flower borders; other special prizes are given by the residents. The plots are kept and cropped in a manner much above what is usually seen in allotment gardens. In one of the first-prize plots I noticed all the following kinds grown—viz, Potatoes, Carrots, Parsnips, Beet, Turnips, Onions, Leeks, Shallots, Radishes, Tomatoes, Lettuce, Cabbage, Cauliflower, Peas, Broad Beans, French Beans, Scarlet Runners, Vegetable Marrows, Broccoli, Curled Kale, Brussels Sprouts, Herbs, Currant and Gooseberry trees, and Rhubarb. Most of the holders have a small greenhouse or frame for Cucumbers and plants. The flower borders contain Roses, Carnations, Stocks, Pansies, Sweet Peas, Dahlias, Fuchsias, Geraniums, Lobelias, Verbenas, and many good kinds of hardy herbaceous plants. Bee-keeping is also encouraged.

The allotments have been established twenty-one years, and are situated on the property of the Baroness Burdett-Coutts, whose interest in the welfare of the working classes is well known.—William Coomber, 106, *Huddleston Road, Tufnell Park, N.*

THE YOUNG GARDENERS' DOMAIN.

Melons in Pots and Frames.

For an early crop Melons are the best grown in pots. The plants should be transferred from the small pots into 5-inch, and afterwards into the 11 or 12-inch size, leaving ample space for top-dressing. Plunge the pots up to the rims in the hotbed, and give the plants the same treatment as described on page 83 for those planted in beds.

For cultivation in frames make a hotbed of litter and leaves about 3 feet deep, and at least 1 foot wider each way than the frame. Tread firmly, and then place on the frame, with a southern aspect. Sprinkle a small quantity of soil over the bed inside the frame, and place a narrow ridge across the centre. When the steam from the bed is exhausted the plants may be inserted about 2 feet apart. Stop them at the fourth joint, and allow three growths to extend, training them equidistantly over the bed. When the growths have nearly reached the side of the frame they must be topped, also all side shoots at the second pistillate or fruit-bearing flower.

When the fruits have set, thin out those which are not required, allowing each plant to carry three Melons. Remove all sub-laterals, and never allow the foliage to become crowded. Place a piece of board or slate under the fruit to prevent its being disfigured by coming in contact with the soil.

Enemies.—Red spider, with green and black fly are partial to Melons. The former is far the worst, and a constant search should be made for the pests. As soon as they put in an appearance the leaves should be sponged with a weak insecticide. I do not know whether nicotine vapour will kill red spider on Melons without injuring the leaves. For black and green fly syringe the plants with a weak solution of quassia, or fumigate.

Diseases.—Canker, one of the most common, and is caused by keeping the bed too wet, especially near the stems of the plants, and having an over-moist atmosphere. The decay may be stopped, if not gone too far, by rubbing the infected parts with a mixture of powdered charcoal and lime.

Anthracnose.—This is by far the worst disease. It affects the fruit when commencing to ripen. Two years ago I was in charge of a large house that was attacked with this disease. It was observed by two of the fruit turning a paler yellow than was desirable. Upon examination a dark spot, about the size of a sixpence, was found upon the under side, and inside fermentation had commenced. A day or two afterwards, two or three more began to go, and upon examining the crop we found the majority infected, some of them on the top side. At first we thought it was a bacterial disease, but afterwards ascertained that it was anthracnose, a disease caused by the fungus Gloeosporium.* Several remedies were tried, but all proved failures. One of them was rubbing the infected parts with lime. This prevented the dark spot from spreading, but not the inside from fermenting. Out of 180 Melons in the house only about eighty were available for dessert. The house was given a thorough cleansing, and a fresh start made with new seed, and no trace of the affection appeared again. Since then I have eagerly scanned the horticultural papers to see if any remedy was given, but as yet nothing has appeared, nor any reference to the subject. Perhaps Mr. Abbey may afford us information.—Elveden.

Means and Modes of Propagating Plants.

(*Continued from page* 83.)

Sometimes the underground portion of a plant assumes the form and functions of a stem to a certain extent, running sometimes above ground and partly below ground, but generally the latter, and sending up shoots into the air from the upper surface and roots into the ground from the surface below.

When the stem assumes this root-like form, as it does in Ginger (Zinziber officinale) and Solomon's Seal (Polygonatum), it is called a rhizome, which means "that which has taken root." The Primrose and kindred plants afford examples of natural propagation by rhizomes, for the stem of the Primrose instead of being upright and ascending, as in the great majority of plants, and attached to the roots below ground by a collar, is an underground stem, or nearly so, thrust forth laterally from the plant, and from this the leaves and blossoms immediately grow, and the roots issue, taking a downward course into the earth.

* Our correspondent does not say by whom the precise nature of the disease was "ascertained." The "ferment" in the diseased parts of some Melons has been found to "swarm with bacteria."

In other plants Nature has resorted to an entirely different kind of propagation. In these a loose trailing branch or stem, called a stole or stolon, is sent forth from the plant at the summit of the root, just where the leaves spring from the stem. This branch or stem proceeds from the original plant to some distance, and then takes root downwards and sends forth leaves upwards, frequently continuing its growth beyond the first attachment to the soil and rooting at intervals, forming a new plant at each rooting. Plants that propagate themselves in this manner are called stoloniferous. The Strawberry affords a familiar example.

Speaking broadly, natural propagation is effected by the development of a bud which proceeds from some portion of the plant, either root or stem, as the case may be—that is, below the surface of the ground, or from the stem proceeding from it at a point just above the surface. Examples have been already given. No matter what may be the mode of propagation that Nature selects, the offset, when ultimately separated from the parent plant, assumes a separate existence, and becomes an independent plant, similar in every respect to that from which it sprang. Thus the suckers thrown up from the root of a Rose or any shrub that throws up shoots of this kind from below ground, when detached with a portion of the root, will speedily form new and strong plants.

The rhizome of the Primrose and Polyanthus may be removed from the parent plant, and will soon send forth roots under favourable circumstances, if it be not already rooted before removal; and when the new plant springing from the stole of the Strawberry is once attached to the soil by roots of its own, the connecting link between parent and offspring may be cut away, rendering the latter dependent on itself for obtaining a supply of nourishment through its own roots. Every plant is provided by Nature with a suitable means of reproduction, whether by seed, sucker, stole, or rhizome.—C. W. M.

(To be continued.)

HARDY FRUIT GARDEN.

Watering and Mulching Fruit Trees.—Fruit trees and bushes having abundance of roots near the surface of the soil are benefited at this season by a copious watering, followed by a mulching of short manure. It is not advisable to water fruitless trees too freely, providing they are well established and making satisfactory growth. Weakly trees and those recently planted will almost certainly need the soil moistening, so that the roots may have a chance of extending and multiplying. After this has been done, immediately apply a mulching in order to conserve the moisture as long as possible.

Wall trees mostly require applications of water frequently; young trees advancing in size and older trees bearing crops should receive adequate supplies of clear water first, in all circumstances where the soil is very dry. If more support is needed, either to increase the growth of wood or to improve the size of the fruit, liquid manure may be given, but not to dry soil. Wall trees well established with their roots deeply in the soil do not suffer from dryness to the same extent as the more surface rooting trees. A mulching, however, to them will be beneficial.

Destroying Red Spider on Wall Trees.—Peaches, Nectarines, Apricots, and Morello Cherries that produce their fruit on young wood which is reserved one season for fruiting the next are frequently subject to attacks of red spider. This pest infests the leaves, abstracting from them their juices, preventing the buds in their axils receiving the nourishment and support required. Trees attacked in this way are evidently dry at the roots. Possibly they may be crowded with other trees, which drain away food and moisture from the soil. Insects, including red spider, soon attack impoverished trees The best remedy is to loosen the surface soil and give a liberal application of water to reach the lowest roots. Then syringe the trees with a solution of 2 ozs. of softsoap to a gallon of water, mixing in a little sulphur formed first into a paste with water. Syringe the trees vigorously with this, repeating the application several times; also use plenty of clear water. Thin out crowded growths.

Strawberries.—*Cleaning Beds and Propagating.*—As the fruit is finished gathering from Strawberries proceed to clear the beds of weeds and runners. If any plants are required for forming new beds the most promising plants or plantlets should be retained. The latter, not having rooted into the soil, may be thrown on one side without detaching them from the parent plants while the ground is being cleared of superfluous runners and weeds. Loosen the soil with a fork, adding, if necessary, a little fresh material to mix with the staple. Secure the plantlets upon this to form roots; water and prevent them being crowded, eventually lifting and planting. Those already rooted must have the surrounding runners thinned out, giving the selected plants room to develop.

Mulching.—After the clearance of superfluous growth from between the rows, should the soil be bare and hard slightly break the surface, then spread a layer of short half-decayed manure. It will tend to keep the roots cool and retain the most fibrous near the surface, where they can spread in the rich medium furnished by the mulching. Strong and healthy fruiting plants will be benefited by the additional support which this treatment affords, and it would materially assist any not making sufficient growth.

Young and vigorous growing plants, however, not having arrived at a fruiting stage might be induced to grow too vigorously with such generous treatment, and it may be advisable to apply it to them but sparingly, provided they were planted in good well manured soil, but a thin top-dressing of some light material can be spread as a summer mulch to prevent evaporation from the soil.

Destroying Old Beds.—After the third or fourth year Strawberry beds are not so profitable as younger plantations. Hence it is desirable to plant a fresh bed every year and destroy the oldest. The beds for destruction should be decided upon immediately fruiting is over. The plants may be chopped off close to the soil, allowed to wither, and then be burnt. The ground they occupied will be greatly improved for whatever crop is to follow by trenching. Avoid planting Strawberries immediately on the same plot of ground if possible.

Preparing Soil for Planting Strawberries.—Deep culture and liberal manuring previous to planting are the foundations of success. Ground not naturally rich, deep, and fertile can be improved by trenching and the addition of manure. In trenching a hungry subsoil must not be brought to the surface and the good soil buried. Preserving the layers of soil in their original position is usually the best plan, but the whole ought to be moved and the bottom well broken up. It is best to prepare some time previous to planting, in winter or early spring. Some early matured crop, such as early Potatoes, may then be taken, which will leave the ground in excellent condition for planting.

FRUIT FORCING.

Vines.—*In Pots for Early Forcing.*—The canes for starting in November, to ripen Grapes in March or April, ought now to have the wood thoroughly ripe and the buds plump. If not, keep the house rather warmer by day, 80° to 85°, closing early so as to raise the temperature to 90° or 95°, and throw the house open at night. The foliage must be well exposed to light, and as near the glass as possible without touching. Supply water or liquid manure in the case of Vines not inclined to luxuriance in sufficient quantity to prevent the foliage becoming limp, but do not give it until the soil is getting dry.

Lateral growths must be kept in check, leaving no more than are absolutely necessary to appropriate any excess of sap, and so prevent the principal buds starting. When sufficiently ripened, as they are when the wood becomes brown and hard and the eyes are prominent, they should be removed to a position outdoors in the full sun, standing them on boards or slates in front of a south wall, fence, or building, securing the canes to the face of the wall, only giving water to prevent the leaves falling prematurely, and having some waterproof material at hand to throw the water from the pots in case of heavy showers occurring. In this position they will rest, even if the leaves are not actually shed, provided they are not kept too moist. When the leaves turn yellow commence reducing the laterals, and when the foliage is all down cut them close to the cane, but without injury to the buds, and shorten the Vines to the length required, or from 6 to 8 feet. Dress all the cuts carefully with styptic or patent knotting. The Vines should be placed in any cool, airy, dry place until required for forcing. Though dryness at the roots is desirable, the soil must not be allowed to become dust dry, and the pots must be protected from frost by some dry material placed round and over them. It will not, of course, be necessary if frost has not access to the house.

Earliest Forced Planted-out Vines.—A dry atmosphere is now necessary, not so much to ripen the wood as to induce rest. All laterals must be kept stopped and the house cool, with moderate dryness at the roots. The inside border may require water, for it is essential that the roots be kept healthy, and the soil not allowed to crack, but if the border has been mulched watering may not be necessary. A moderate extension of the laterals will be sufficient to keep the principal foliage in health. Where the Vines are in an unsatisfactory condition preparations should be made for lifting, getting fresh loam and clean drainage, so that the work can be quickly done when begun. One part of the border only need be operated upon at once, the inside one year and the outside the next. This prevents loss of crop. The roots should be lifted and laid in fresh soil nearer the surface whilst there is foliage on the Vines; therefore work of this nature ought not to be delayed beyond the early part of September in the case of Vines that ought to be started early in December. The Vines will need pruning by the middle of September or, when lifted, a little later.

Houses Required for Early Forcing.—Vines that have not been forced early hitherto, and are required for that purpose, will, as soon as the crops are off, need to be thoroughly syringed to cleanse them from pests, applying an insecticide if necessary, and if there is any doubt about the ripeness of the wood or the plumpness of the buds it will be necessary to keep the house rather close by day, but with sufficient ventilation to cause evaporation and allow the moisture to escape. Give no more water than will prevent the foliage becoming limp. If the weather prove wet and cold employ fire heat in the daytime to maintain a temperature of 70° to 75° with moderate ventilation, and turn the heat off at night to allow the pipes to cool, increasing the ventilation so as to induce a thorough draught, and this will soon cause the wood to harden and the buds to plump, insuring rest, which for Vines to be started in December should be complete from the middle to the end of September. When the wood is ripe ventilate fully day and night.

Vines Cleared of Grapes.—Through crops hanging after being ripe the Vines often become infested with red spider, and by growing plants in the house they are sometimes attacked by scale and mealy bug, the dry atmosphere encouraging thrips. Thoroughly cleanse the Vines, fumigate on two or three consecutive evenings for the thrips, and repeat in a week or ten days; syringe forcibly two or three times to eject red spider. Mealy bug and scale may be eradicated by syringing with the following solution:—Softsoap, ¾ lb.; water, ½ gallon. Dissolve by boiling, and while hot add 1 gill (¼ pint) petroleum, stirring briskly till emulsified; then dilute 6 gallons with hot water, and when cooled to 100° apply with a syringe, wetting every part of the Vines. Repeat in the course of four days or a week, and again at a similar interval. Have the laterals fairly in hand, not closely pinched, unless the Vines are very vigorous and not ripening the wood kindly, when keeping the house rather dry at night, with all the ventilation possible, and somewhat close and warm by day, will promote the ripening of the wood and buds. In stopping vigorous Vines regard must be had to the principal leaves and buds, for when all the growth is removed as made and the leaves injured it may cause the pruning buds to start, which must be avoided by allowing a little lateral growth and keeping the soil dry at their roots to the extent of causing the foliage to become limp. Weakly Vines may be fed with liquid manure and the laterals allowed to extend, but whatever extension is permitted the extraneous foliage must not in any way interfere with the free access of air and light to the principal leaves, which must be kept healthy, and thus appropriate some of the food and store it in the buds and adjacent wood. Free ventilation will be necessary day and night.

Grapes Ripening.—Whilst ripening Grapes swell considerably, therefore do not allow any deficiency of moisture in the border. Give if needed a good supply of water or liquid manure, and in the early part of the day, so that superfluous moisture may be dissipated before night. Heavily cropped Vines require time and copious supplies of liquid manure, which if it does not help the current crop, will prevent the exhaustion of the Vines. A good rest at night in a temperature of 60° to 65° with air is a great aid to Vines taxed to the utmost by weight of Grapes. A moderate amount of air moisture also is essential to the health of the Vines, sprinkling the paths and borders occasionally, and if possible allow the laterals to extend, but full or overcropped Vines rarely can cater for more than the principal leaves and Grapes. Admit air constantly, enough with a gentle heat in the pipes to insure a circulation, and maintain a temperature by day of 70° to 75°, keeping through the day at 80° to 85° or 90° with sun and full ventilation.

Melons.—*Late Fruit.*—A sowing should be made to afford very late Melons. The plants will be fit to plant out in about a month, they will set fruit in September, and that will be ripe in November. A light airy structure, well heated, is essential with high culture for this crop. Bottom heat is necessary, and is best afforded by hot-water pipes, but if had from fermenting materials they must be thrown into a heap, watered, and turned, so as to insure the needful fermentation, and escape of rank steam.

Early Autumn Fruit.—Good looking fruit is always esteemed, if only from a decorative point of view, and when the quality is of a high order the advantage is duly appreciated. To have fruit in October the plants must be planted out at once, giving them about a barrowload each of soil made into a flattened cone or ridge about 10 to 12 inches deep in the centre. Rather strong loam, with a fifth of sweetened horse droppings, and a sixth of old mortar rubbish, form a suitable compost. Make this quite firm, and have it in a moist state before planting. Turn the plants out carefully, watering them overnight, so that the roots may come freely from the sides of the pots, and make the soil firm about the ball. Keep the stem slightly raised, and water to settle the soil about the roots. The plants must be encouraged to make a free growth by syringing at closing, and damping the paths and walls in the morning and evening of hot days. Ventilate between 70° and 75°, and keep the temperature through the day at those degrees by artificial means, 85° to 90° from sun heat, and close so as to raise to 95° or 100°. Through the night the temperature may fall to 65°.

Fruit Swelling.—The ultimate result must be kept in view from the start, as sturdy plants only can produce fine fruit, and this may be spoiled by overcropping the plants. When the fruit is fairly swelling the crop should be reduced to two on a weakly, three on a moderately vigorous, four on a strong, and six on a large plant. Overcropping is very prejudicial to the plant's health, and unless the foliage is kept in good condition to the finish high quality, which mainly depends on solidity through the high elaboration of the juices, cannot be expected; therefore keep the foliage fairly thin, all having full exposure to light. Earth the roots, giving copious supplies of water or liquid manure, and damp the paths with liquid manure twice a week, but it is best to give it often and weak. The drainage of stables, not containing washings, should be diluted with five times the bulk of water.

Fruit Ripening.—The atmosphere should be kept dry, and a top heat maintained of 70° to 75° by artificial means, admitting a little air constantly, a circulation of rather dry warm air greatly improving the quality and finish when the fruit is ripening. Water should be withheld from the house unless there is fruit advanced in swelling, when an occasional damping will be necessary for the benefit of the foliage.

Plants in Pits and Frames.—The latest plants will be setting their fruit, it being important that the fruit be set at the close of July or early in August to allow time for its swelling and ripening. Give a good watering, if necessary, before the flowers open, and line the sides of the bed and frame with hot dung, or the mowings of lawns, and give a little ventilation constantly at the top of the lights until the fruit is set and commences swelling. This prevents the deposition of moisture on the blossoms and insures a good set. Fertilise the flowers daily, and when sufficient are set, and the fruit swelling of about equal size, remove all flowers, and keep the growths thin and well stopped, maintaining a warm moist atmosphere, but not stagnant, by early closing with sun heat. Sprinkle the foliage on fine afternoons, and afford water in bright weather about twice a week.

Cucumbers.—Where it is desired to have fruit in the autumn and onward through the winter, seeds may be sown early in August, and the plants being ready for planting early in September, they will, in a light, well-heated structure, with a good bottom heat, give fruit through the autumn months, and, not then being overcropped, continue in bearing during the winter, a succession of bearing wood being maintained by cutting out exhausted and training in young for the purpose. The soil for growing them where eelworm has been troublesome should be disinfected, there not being anything cheaper or better than soaking with boiling water. This acts admirably, so also does mixing with the soil about 5 per cent. of best chalk lime, using it when freshly slaked, and mixing with the soil as evenly as possible. Allowed to lie a month to six weeks, it renders the turf mellow and in excellent condition for use.

THE FLOWER GARDEN.

Bedding Antirrhinums.—The white bedding variety forms a very attractive bed, the flowering period being fully equal to that of the majority of other plants used. Several newer forms suitable for bedding have also been introduced. In order to have strong plants ready for planting early next season, and which only can be depended upon for a good effect, propagating should commence now. Short flowerless shoots, slipped off from old plants, will root readily in a cold frame or hand-lights at the foot of a north wall or other cool and not too dark position. Dibble three or four of the cuttings round the sides of 3-inch pots filled with gritty loamy soil, give a gentle watering, and keep close and shaded during the hottest part of the day till they are rooted. Some could be wintered in pots, and the rest planted in sheltered nursery beds.

Antirrhinums from Seed.—The white bedding and other named Antirrhinums come quite true from seed, and this is the readiest means of raising a large number of plants. Now is a better time for sowing than early next year, and this season's seed will germinate more strongly than older seed. Sow the seed thinly on the surface of previously moistened pans of light sandy soil and very lightly cover with fine soil. Cover with a square of glass and either moss or paper, and place in a cool frame or hand-light at the foot of a north wall or fence. When the seedlings are large enough prick out in boxes of light soil. Being fairly hardy, some may be planted out in nursery beds and the rest be wintered in a cold frame.

Pentstemons.—These again are seldom very effective the same season they are propagated, but plants raised now from either cuttings or seed would do remarkably well next summer. Both cuttings and seeds should be treated exactly as advised in the case of Antirrhinums. Where hardier bedding plants are preferred to the more tender kinds, Pentstemons ought certainly to be given a place. Strong old plants are most suited to mixed borders, but late summer or autumn raised plants placed out early into large well prepared beds and lightly staked up would prove quite a feature in the display. A mixture of Pentstemons and Nicotiana affinis is both bold and pleasing. As many as are wanted should be wintered in cold frames or pits, as a very severe winter is sometimes fatal to most of the exposed plants.

Tuberous Begonias.—If short flowerless side shoots of these are made into cuttings, dibbled rather thickly in pans or boxes of fine sandy soil, set in the full sunshine and sheltered from heavy rains, the majority will strike root and form tiny tubers before the tops die down. Left where they are, and stored in a dry cellar or shed where severe frosts cannot reach them, these small tubers will winter well and be very handy for bedding next season. Now is also a good time to sow seed with a view to having abundance of small tubers to make an early start with next season. Quite new seed will germinate very quickly and strongly, and this should be preferred, though last season's seed will not fail if sound at the time of sowing. Prepare several pans or boxes, by careful draining and filling up with fine light sandy soil. Make the surface very level and firm, but do not sand over, give a gentle watering, and about one hour later sow the seed thinly, quite on the surface, no covering over being attempted. Place in a cold frame on inverted pans or pots with a view to excluding worms, cover with squares of glass, and shade heavily. The soil must be kept uniformly moist, not by waterings, but rather by partial immersion in a tub or tank of water, the one thing to avoid being the disturbance of the germinating seed. The seedlings will not make much growth, but if undisturbed will form tubers near the size of Radish seed. Such, if kept plump till next March, will be available for growing into strong plants by the time they are wanted for the flower beds.

Chrysanthemums.—If there are any bad failures in the flower garden, and the late hot and dry weather proved very trying in many cases, some of these might be made good by either planting out or transplanting Madame Desgrange and Mrs. Hawkins. Both of these varieties are very sturdy and floriferous this season, and perhaps would do better service in the flower beds than under glass. If planted in a sloping direction, the tops well spread out, and lightly pegged or

tied down, either variety would form a good groundwork for a few rather tall Cockscombs. A bed or beds thus filled would rank amongst the most attractive feature in a garden.

PLANT HOUSES.

Bignonia grandiflora.—In 5-inch pots this plant flowers profusely, and is very useful for various decorative purposes. Cuttings of young wood root freely in houses where a fair amount of moisture is maintained. The plants should be well ripened and rested in a cool house. When started into growth in the spring an intermediate temperature suits them well if fully exposed to the sun. The wood made must be firm or else the plants fail to flower.

Gloxinias.—Plants raised from seed sown late in the spring and now in small pots should be transferred into others 4 and 5 inches in diameter, according to their size. These, if shaded from bright sunshine and grown close to the glass in cold frames, will make excellent decorative plants a few months hence. Few plants when well grown are more effective. By starting the tubers at intervals of a month and raising seedlings a very long succession of bloom can be obtained. Plants that flowered early and have enjoyed a good season of rest may be started again into growth. They will soon commence to grow in any structure that is kept moderately close. The plants may be flowered in the same pots.

Tuberous Begonias.—Seedlings may be grown in cold frames, for although they may appear to be late they will make wonderful progress, and flower profusely during October and November if placed in a warm house close to the glass where the atmosphere is kept moderately dry. The flowers of these Begonias are very useful for house decoration. They are easily bruised, and therefore do not travel well.

Nertera depressa.—This is really a charming little plant when well grown and covered with its coral-like berries. Plants that have berried well and have started again into growth may be broken up and dibbled thickly into small pots or pans, the latter being best when needed for table decoration. This plant grows freely in any light moderately rich soil, and should be kept moist until well established in an intermediate temperature. By autumn the surface of the pots or pans will be covered with growth, and if well watered we find the plants winter well on shelves where the temperature does not fall below 45°. In spring a fair amount of air and full sunshine should be afforded them, when they will be found to berry freely.

Celosias.—Plants for autumn and winter now in 3-inch pots may be transferred into 5-inch without delay. Grow the plants in frames where they can enjoy a liberal amount of air. They should not be hurried in their last stages, or they will be almost certain to damp at the base when arranged in conservatories and other structures.

Asparagus deflexus.—However effective and useful other varieties of Asparagus may be for furnishing in pots and for supplying greenery for cutting, A. deflexus is a handsome basket plant. It is very distinct in appearance, and its fairly long feathery shoots droop gracefully over the sides of the basket. This is certainly a great acquisition to the numerous basket plants at disposal.

Epiphyllums.—These, if assisted by gentle warmth to make their growth, should now be fully exposed to the sun, and at the same time be given abundance of air. They flower profusely when the growths are thoroughly ripened, which is best accomplished by exposure to light and air, and not by the barbarous system of drying them at their roots until the plants shrivel. Where stage room is limited these plants do well grown in pots suspended from the roof by means of wire. In this position they do not suffer so quickly from the drying conditions of the atmosphere as many other plants. Even in baskets the plants do very well, providing they are not overwatered. If strong stocks of Pereskia are at hand they may be cut into lengths and inserted in small pots. If pieces of Epiphyllum are attached on the top and then stood in the propagating frame they will unite by the time the stocks are rooted. Grafting is easily effected by splitting the stock at the top and the removal of the bark from the scion, or by placing pieces on each side after removing a portion of the stock, so that the two barks come together. When placed on each side of the stock, and each scion pointing outwards, they form good shaped heads much quicker than when one piece only is attached.

MISSOURI BOTANICAL GARDEN.—The Trustees have decided to to add 100 acres to these gardens, and plans are being prepared by the Messrs. Olmsted of Boston. The work of making extensions and improvements will begin during the present summer, and will cover a period of five years. This season will be devoted to grading and the laying of water pipes. Next year the planting will begin. The year following the walks will be laid out. The fourth year the herbaceous plants will be put in, and in the fifth year the work of preparation will be completed. The proposed improvements are the beginning of an entire remodelling of "Shaw's Garden." The instructions given to the Messrs. Olmsted were—first, for a general plan for improving the farm land adjoining the garden; second, a detailed plan for the North American synopsis, and a small department of medical botany; third, suggestions for the gradual modification of the present park to harmonise with the improvements. According to a contemporary, Professor Trelease, who has embodied the plans in his forthcoming annual report, considers that the improvement will place these gardens in a foremost position among the famous botanical gardens of the world.

THE BEE-KEEPER.

REMOVING SUPERS.

SUPERS will now require attention, as it is not advisable to allow them to remain on the hive after they are properly sealed over, or the combs will soon become discoloured, and instead of being of pearly whiteness the cappings will be dark in colour. This is very objectionable, whether they are required for exhibition, home consumption, or marketing purposes. It is not always possible to have all the cells filled with honey, as a sudden change in the weather will often cause the bees to leave the supers and cluster in the body of the hive; but with the perfect bee weather experienced during the past fortnight there can be no excuse on the part of the bee-keeper if supers are not in good condition.

Sections that are well sealed over should be removed from the hive without delay. If there are a few cells not properly finished off place them in the middle of the crate and allow them to remain a few days longer, then in all probability they will be in a fit condition for removal. This is important, as the unsealed cells will drip, which is often a just cause of complaint from dealers who have the handling of them, and prevents them stocking a supply of sections as often as they would if they could always rely on them being dry and otherwise in good condition. It is now too late (except in Heather districts) to fill up the vacant space in crates with empty sections. The bee-keeper's aim should be to endeavour to obtain as many well-finished sections as is possible. This can only be done by placing the partly filled sections close together directly over the brood nest, the empty space being filled with some warm material to prevent the escape of heat from the hive.

REMOVING GLASS SUPERS.

Although glass supers are now not nearly so common as formerly, when the majority of bees were kept in straw skeps, still many bee-keepers who manage their bees according to modern ideas have a fancy for at least one glass super in their apiary. This is not to be wondered at, for what is more interesting to many people other than bee-keepers than a well-finished bell-glass of honey?

Many of those that are in use for the above purpose are most inconvenient for table use, the combs having to be removed bodily and placed on a dish or something similar. The most useful bell-glass that I have used for that purpose was obtained from Messrs. Neighbour & Son, High Holborn. It is circular in shape with straight sides, which are about 9 inches in depth, a lid with a knob on top is supplied with it, which gives it a very handsome appearance when placed on the table. The lid also prevents flies from gaining access to the honey, which is a great advantage when stored away.

Before attempting to remove a bell-glass from the hive a piece of fine wire or string should be drawn under the glass so as to cut through the comb, which will be fastened to the board on the top of the hive. When this has been done place some thin wedges of wood under the super so as to leave a clear space between the comb that has been severed, otherwise the bees would connect them again, but not of sufficient height to allow the bees to escape. Cover the super again and allow it to remain on the hive for at least two or three hours, which will give the bees ample time to clear up the dripping honey. The combs will thus be dry and the super may be handled with impunity.

On removing the super carry it bottom upwards some distance from the hive. If the glass is darkened by being wrapt in some of the coverings from the hive the bees will come to the light, when they may be brushed off with a feather, and will at once fly back to their hive. If the bees will not leave the super freely a little smoke blown into the glass will cause them to do so. It is better, however, not to use smoke if it can be avoided, as it may give an unpleasant flavour to the honey.

CARBOLIC *versus* SMOKE.

In handling bees it is necessary to have something at hand for quieting them. It is, however, a disputed question what is best for that purpose. For general purposes I prefer a Bingham smoker, and I know of nothing better when examining stocks in the spring. If the weather is warm it is often not necessary to use anything at all, but if the bees are inclined to be troublesome a gentle puff or two from the smoker will quiet them. Afterwards when removing supers, either full-sized frames or sections, I now make it a rule never to use smoke in any form, as a carbolic cloth is much better. This is very simple in preparation and use. All that is required is a piece of unbleached calico, slightly larger than the top of the hive intended to be operated

on, sprinkle the calico with a few drops of carbolic, and it is ready for use. First remove the covering from the top of super, and lay the carbolic cloth in its place. The bees will at once beat a retreat, and in a few minutes the super will be quite clear of bees, and the most timid bee-keeper may handle them with impunity. For this purpose carbolic cloths are strongly recommended, but a smoker is preferred when examining the brood nest, as if carelessly handled the carbolic would drive all the bees from their hive.

But whatever bee deterrent is used it is well to bear in mind that it is often quite unnecessary to use anything. Careful handling is essential to success, and the less bees are examined the better. A bee-keeper who has only two or three stocks will often spend more time manipulating them than another who has ten times the number, the former half suffocating the bees with smoke, whilst the latter who has his smoker handy will use it only when really necessary, and the bees are less disturbed in consequence.—AN ENGLISH BEE-KEEPER.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary*, Mr. A. F. Barron, The Royal Gardeners' Orphan Fund, Chiswick, W.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," *8, Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Propagation of Conifers (*J. Thompson*).—You will find on page 91 an article on the propagation of Conifers and shrubs which is certain to be of assistance to you. It is from the pen of a thoroughly practical man, and the information is reliable.

Seedling Carnations (*W. Pearce*).—Owing to your flowers being wrongly addressed they were so much shrivelled when they reached us that it was impossible to form any reliable judgment as to their merit. When sending in future kindly comply with the directions printed weekly at the head of this column.

Pear Tree Leaves Eaten (*W. Fry*).—The "sort of caterpillar" which has been grazing on the leaves you have sent is known as the slimy grub or Pear slug, the larva of the Pear saw fly, Selandria atra. The slime on the body is not dried by exposure to the hottest sun. This covering is, however, cast as the season advances, and the grubs are then clay coloured. They form cocoons in the autumn, rest in the soil, and from them the perfect insects emerge the following summer, the females depositing eggs on the upper surface of the leaves, from which the grubs are hatched. We have found, as have others, that dusting with freshly slaked lime destroys the grubs. We have also found it decidedly advantageous to remove 3 or 4 inches of surface soil from around the trees, give a good dressing of lime and soot, covering with fresh soil. If you find petroleum and soapy water the best remedy, and the mixture does not injure the leaves, by all means use it. Perhaps a few light sprayings in June and July might prevent the flies depositing eggs. It is generally safer to apply petroleum mixtures in the evening than in the morning, because if hot sun follows while the leaves are wet they are liable to be scorched.

Seeds for Chiswick (*Brassica*).—The proper course to pursue is to write to the Secretary, Royal Horticultural Society, 117, Victoria Street, Westminster, on the subject.

Unknown Plant (*S. J. A.*).—If you can oblige with the botanical name of the plant, so that we may be able to identify it, we shall be glad to give you any information we can on its cultivation. Good King Henry is one of the fanciful names of the Lincolnshire Mercury (Chenopodium bonus Henricus), but we doubt if this is the plant you have in mind.

Paraffin-Napthalene Emulsion (*K. J. N.*).—We are unable to give you the desired information. The preparation, as you say, is "not advertised," and we really do not know whether it is on sale generally or not. The "Patentee's" letter gives you as much information as we can, but he, as he stated, is not personally interested in the sale of the product. We do not know the address of the proprietor.

Early Rivers Nectarine Splitting at the Stone (*W. H.*).—This variety has been so short a time in commerce as not to enable us to say if it is accustomed to this serious defect. The specimens have not come to hand, hence we cannot form any opinion as to what caused the splitting. In your case it may be due to the tree being overfed in the later stages of swelling, the roots of the tree then only having got extensive possession of the soil, and transmitted more nutriment than could be utilised; hence the cracking of the flesh and splitting of the stone, both too hard to bear the tension and growth of new cells. See "Peaches Decayed and Hollow," page 86.

Cucumber Plant Diseased (*T. A.*).—The fine plant and excellent specimen for examination was found perfectly healthy in the leaf and stem, also on the root-stem for 6 inches or more downward from the collar of the plant, and even the main lateral roots were quite normal. The small roots or fibres are knotted, numerous small knobs being on them, and the effect of this is to arrest the ascent of the nutrition absorbed by the young fibrelets, in consequence of which the foliage of the plant becomes sickly in appearance, and this results in gradual collapse. In the knobs were eelworm, fine examples of Tylenchus devastatrix, *Kuhn*, and its cysts or eggs in various stages of development. We advise you to use Little's soluble phenyle in the proportion of 1 gill (quarter pint) to 3 gallons of rain or soft water, applying as in an ordinary watering. It may be necessary to repeat the application occasionally, and in such cases half the strength suffices. The soluble phenyle acts as a manure, besides compassing the destruction of the eelworm. Nitrate of soda, quarter ounce to a gallon of water, also acts well against the eelworm, especially when used in conjunction with soluble phenyle (see article by Mr. W. Iggulden in our issue of February 18 h, 1897, page 130).

Woodlice in Eucharis Pots (*Subscriber*).—The fact of the soil, which was scorched before using it for the Eucharises, being "full of woodlice," suggests that it has been kept more than ordinarily dry, and too dry, we are inclined to think, for the well-being of the plants, while favourable to the increase of their enemy the mite. We have never known woodlice to swarm in soil which is kept sufficiently moist for the h alth of Eucharises. We should give the plants a good watering to "swell" the soil, then follow with clear soot water of the colour of pale ale. This would not be palatable for the woodlice, which would find means of escape, while it would benefit rather than injure the plants. The best thing to do, then, is to catch the pests. The old plan of placing a boiled Potato in each of a few flower pots, covering rather thickly but somewhat loosely with dry hay, and laying the pots where the woodlice abound, will attract many of them. Another simple method is to take two dry dirty old boards and place them face to face, with just sufficient room between them for the pests to enter. We have seen thousands of the woodlice caught in this way, and ended in a moment by casting them into boiling water. It is said that a sprinkling of oatmeal or crumbled potato on the lower board causes the pests to congregate the more quickly. By perseverance in the methods proposed you may clear the house of woodlice.

Madresfield Court Grapes Diseased (*Grower, Darlington*).—The leaves and berries are attacked by anthracnose fungus (Sphaceloma ampelinum), but in a very mild form. The tendency to crack is also accelerated in the berries, as appears in your specimen. There are not any "fruits" of the fungus on either of the leaves or berries, but there will probably be some borne on the young wood. They appear as minute pustules on the epidermis, through which the spores push and are scattered far and wide. That the atmospheric conditions of our vineries are unfavourable to their germination is evident from its attacking some varieties in the same house and leaving others, evaporating more freely, severely alone. It appears to prefer light coloured or somewhat delicate varieties, especially those not in vigorous health. The treatment advisable is to cut off all injured canes during winter, as will be done in pruning, and burn them. When the house has been cleansed in the usual manner dress the Vine, with all the rods in the house, with a solution of sulphate of iron, 1 lb. to 1½ gallon of water, applying with a brush to every part of the rod, not missing any part, but taking care not to injure the buds. Do not practise peeling the rod, as the iron sulphate on raw bark may sink in and do mischief, but we have not found any result. It must be used whilst the Vine is quite dormant, but preferably just before the buds start. It is needless to say that all fallen leaves should be removed and burnt. As a further preventive measure you may dust the Vine with a powder formed of equal parts best chalk lime, air-slaked, and flowers of sulphur when the leaves are fairly formed. We find the sulphate of iron quite sufficient. Use fertilisers freely.

Cockscomb Plant Diseased (*C. B.*).—The plant is perfectly healthy at the roots, bnt infested in the leaves and "comb" by a minute insect or rather mite, which affects Pelargoniums, especially Ivy-leaved and Zonal, and is a very malignant pest on Begonias, Gesneras, and Gloxinias. It is somewhat difficult to find, but its bite appears to be very poisonons or injurious, as the attacked foliage becomes rusted and browned, as if injured by some corrosive substance, and Begonias oftentimes cast their leaves altogether, especially tuberous-rooted. There is no preventive or remedy but frequent fumigation with tobacco paper, or vaporisation with nicotine essence. Of course insecticides in the form of washes are equally effective, but you must know what effect these have on hairy-leaved plants, and exercise judgment accordingly.

Tomato Fruits Diseased (*F. J.*).—The fruit are affected with "spot," "blotch," "black stripe," or Tomato rot, which we are now in a position to say is the fungus known to botanists as Macrosporium tomati. The malady usually becomes first noticeable when the fruit is about half grown, appearing at the blossom end, commonly as a depressed blister, due to scorching; but oftentimes the disease appears earlier as a small blackish spot or stripe, which increases in size as the affected Tomato develops. The flesh beneath the spot is destroyed by the fungus, causing the fruit to become flat on the top, and the inside of the Tomato is blackened, some of the seeds destroyed, others only partially so. In some cases, and always ultimately, the fungus involves the interior of the fruit entirely, producing a shrivelling and blackening, and finally a rotting. Now as to preventive measures—(*a*) Use thoroughly decayed manure, if any, for enriching the soil, and use "artificials" supplying a large per-centage of lime, preferably free basic slag phosphate. (*b*) Have the soil firm, so as to induce a sturdy habit. (*c*) Give the plants plenty of light and air from the time of seedlings appearing above the soil. (*d*) Admit air day and night, so that the plants and fruits may dry quickly, if syringed, and moisture not be deposited. (*e*) Paint the hot-water pipes thinly with a cream formed of flowers of sulphur and skim milk, and occasionally heat them to over 170°, so as to give off fnmes, never being afraid to have a little warmth in them in dull weather or when needful to keep the air of the house in motion. (*f*) Avoid straw or partially decayed stable or farmyard manure as a mulch, employing a little air-slaked best chalk lime, about 7 lbs. per rod as a top-dressing. (*g*) Dust the plants as soon as they show flower with some preparation of sulphate of copper in powder, this containing 10 per cent. of sulphate of copper. Apply with a bellows apparatus in as fine and light a manner as possible, and keep coated as new growths and trusses are made. (*h*) Grow the less improved corrugated varieties, or the small Cherry and Plum sorts, as they are the most exempt from the disease. Do not save seed from diseased fruits. We attribute your attack by the fungus to the mulching with farmyard manure six weeks ago. Apply some lime or basic slag phosphate.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*A. M. M.*).—Epidendrum nemorale. (*K. W. G.*).—1, Lychnis chalcedonica; 2, Rudbeckia laciniata; 3, Erigeron speciosus; 4, Chrysanthemum maximum; 5, C. segetum; 6, a variety of Aërides odorata. (*A. F. R.*).—The Iris is a charming form of I. longipetala, which varies much in size and colouration. (*J. H.*).—1, Galega officinalis alba; 2, Tradescantia virginica; 3, Polygonum brunonis; 4, Ruta graveolens; 5, Lysimachia nummnlaria; 6, Lilium davnricum. (*J. E. M.*).—2, Phlebodium aureum; 3, Asparagus deflexus; 4, A. plumosus nana; the others are quite insufficient for identification; the Grape appears to be White Frontignan. (*J. D.*).—The flower is of Alstrœmeria aurantiaca; possibly the leaf is Strelitzia reginæ. (*G. F.*).—Lælia crispa. (*S. K.*).—Nymphæa cœrulea.

"SAILING THE LOWLAND SEAS."

We English are a mixed race; the ancient woaded, skin-clothed Briton, the polished war-like Roman, the Saxon marauder, the Norseman, Viking, and the cold, proud Norman, all contribute to our making. We have fought and wrangled and contended with all, and all have left their impress upon our national character. Our old foes are turned into friends. No more does the Norseman with his pirate ship devastate our shores in the spring time of the year, no longer do we dread his barbaric cruelties. In science and in agriculture they are now our equals (not superiors, of course), and it was with the hope of learning some of their excellent methods that a select party of British dairy farmers sailed the lowland seas on July 1st. The B.D.F. loves an outing and, more than that, gets one every summer.

We venture to say that no tour could have been better planned. Denmark has of late years been first and foremost in the manipulation of dairy produce, and Sweden seems to have caught the infection. "No one need apply who is afraid of work." Certainly the programme for the ticket-holders made hard work a necessity. "Not a full night's rest for a week after leaving home." Only the able-bodied could stand this, but consider the distance traversed, the manifold objects of interest to be seen, and surely one would feel that all was well worth a little toil. "Steal a few hours from the night, my boy," says an old song, and these fair calm nights in the northern latitudes are things of beauty and joy.

July 1st saw about ninety pilgrims, male and female, leave Harwich for the Hook of Holland, from there by train to Kiel. At that point the party re-embarked for Wedellsborg, on the Island of Fumen. Count Wedell Wedellsborg, one of the

Presidents of the Danish R.A.S.; the British Minister, Sir Charles Scott; Herr Faber, Danish Dairy Commissioner, and others met the party with hearty welcome. The Count's estate extends over fifty-four square miles. The home farm (820 acres) is managed on a nine-course system; 300 head of cattle are kept, 190 of them being cows, all are of the red Danish breed. Now science steps in. Half these cows are subjected twice a year to the tuberculin test (we have not arrived at that in England yet).

Twenty-four breeding sows are kept, and about 300 fat pigs are turned out annually. The horses number about twenty-five. The cows appear the main feature on this farm, and are most carefully selected in their butter and milk qualifications: 500 gallons of milk per annum is the minimum production of any one cow, giving less than that her fate is sealed. Close attention, too, is paid to the bulls, only those the offspring of grand milkers being admitted into the stud book.

Now hard-worked English dairymaids, note this—each woman milks twenty cows *twice* a-day beside doing her other work. Most of these cows calve in the autumn, are kept up till the beginning of May, are then turned out till the end of June, spending July indoors. Now here we may note a point. Our cows invariably run off in this month, yet we look upon it as a necessity; it has hence occurred to us they would do better up in cool cowhouses, with plenty of green food supplied them in hot, scanty pastures. We, too, except in a few isolated cases, have no Mangolds left, neither do we ever use Sunflower cake. In the dairy all the milk is separated, and then the cream is artificially ripened.

A handsome entertainment followed this instructive inspection, and after hearty good wishes, exchanged and received, our party left for Copenhagen. Monday morning early found us at the Copenhagen Milk Supply Co. premises. Here 5000 gallons of milk are received and distributed daily. The milk is first filtered through coarse, fine sand, and a certain quantity is pasteurised, after which it will keep for three or four weeks. Then the babies are not forgotten; specially prepared milk is got ready for them, bottled and sealed. By the aid of ice and pasteurisation the company is enabled to deliver milk only once a day—this must be an immense saving in labour. Butter and four kinds of cheese are also produced at this establishment.

For those interested the cream separator factory of Messrs. Burmeister & Wain was on view, as was also the Scandinavian Preserved Butter Company's factory and the public abattoir. Very properly Government is exceedingly strict in its rules as to the selling of any doubtful meat. The blood from the abattoir is converted into food for pigs and poultry by being mixed with molasses and meal.

On Tuesday a visit was paid to the Agri. College at Lyngby, where are from eighty to 100 pupils, male and female, mostly the children of small farmers. The course of education is purely theoretical, and the full term of work is about nine months.

At Mellose is a co-operative dairy dealing with milk of 900 to 1000 cows. This factory is supplied from 164 farms, all small ones, and the farmers are the managers. Such a factory is found in almost every parish.

At Lund is another factory, owned by 170 members. The price paid for milk is 3½d. to 4d. per gallon. Any farmer requiring separated milk can have it at about 0½d. per gallon. The town price is 1½d. per gallon.

Then, Ho for Sweden! The College and Dairy School are at Alnarp. This is a most comprehensive school, being divided thus:—1, Higher agri. coll.; 2, lower agri. coll.; 3, higher dairy coll.; 4, lower dairy for men; 5, lower dairy for women; 6, a gardening college; 7, a farmery school.

Is anything left out, or any class of student unprovided for? In the higher schools the fees are by no means heavy; in the lower schools part, if not all, the fees are remitted.

A visit was paid to the factory of the Stockholm Milk Supply Company, also the Alpha Laval Separation Works was seen. Here a man may, by piecework, earn 40s. per week—not a bad living wage.

Here in England dairy work and management has been left to the women; other industries, deemed more important, occupying the energies of the farmer. We have made a mistake. No industry is too trivial, and no industry should be relegated to a "back seat," so to speak. Please do not think we disparage our dairymaids, not for a moment. What we say is this, they have had to work on bad material without any scientific training. Neither in the selection of the cows, their feeding, nor in the housing of the milk have sufficient pains been taken; too much has been left to chance. Hence it is that little Denmark, where dairy work and management receive the first and best attention, the dairy outcome is so magnificent. All we can say is shortly summed up in a few words, Do not be too proud to learn, and be grateful to your instructors.

WORK ON THE HOME FARM.

We have got our hay crop well and just in time, for rain has again begun to fall. St. Swithin this year was dry, but barely a week elapsed before there were signs of a break in the weather. The rain is very welcome, as pastures were going off very rapidly, and Turnips, especially the early ones, wanted moisture very much; the Potatoes, too, early as well as late, were inclined to stop the growth of haulm, and it remains to be seen whether there has been sufficient premature ripening to cause second growth and loss of shape and quality. On warm soils, it is to be feared, that such has been the case.

Though grain crops as a rule do not require rain, and in fact would be damaged by it if at all heavy, still a thoroughly good soaking now would greatly benefit the average farmer. The meadows and clover stubbles are very bare and brown, and there will be very little aftermath without a thorough watering.

Corn is changing rapidly, and reapers are being looked over and prepared for work. It is advisable to have at least two spare connecting rods for each machine, for when one breaks it is often a case of misfortunes not coming singly, and a third to fall back on, eats nothing whilst awaiting its turn.

Every effort should be made to finish Turnip cleaning, but if the most has been made of recent opportunities there should be little left to do.

Coal leading, repairs to private roads and gateways, and the trimming of hedges around the premises are items of work to occupy any time there may be to spare from the thatching of the haystacks, which must be completed at once. We are in the unfortunate plight of being without thatch, and have cut all the grass on hedge sides by cart roads and ditches, and topped up the stacks with the mixture; well raked down it will turn a good deal of rain, and at any rate be a protection to the more valuable fodder beneath.

Lambs are doing well, though the rain with its starting of new growth in the pastures may cause trouble. Change of pasture with any dry food that the animals can be induced to eat is the best preventive. Watery, washy food of any kind is bad for lambs at this period.

REMARKS.

18th.—Generally sunny, but haze or thin cloud at times.
19th.—Sun visible most of day, but little bright sunshine. Thunder, lightning, and heavy rain from 7.45 P.M. to 9.30 P.M.
20th.—Overcast early, frequently sunny after 9.30 A.M.; thunder at 2.30 P.M., followed by spots of rain, and generally cloudy after.
21st.—Overcast day; much thunder, a dozen flashes of lightning, and spots of rain between 1.30 and 3.30 P.M.
22nd.—Overcast till about 11 A.M., sunny at times after.
23rd.—A little cloud early; hot sun all day.
24th.—Bright sun almost throughout, with pleasant breeze.

A fine hot week. The thunderstorm in N. London, which gave from 2 to 2½ inches of rain at some places, only gave 0·01 inch here.—G. J. SYMONS.

SUMMER PRUNING.

THE value of summer pruning has long been recognised and largely practised by gardeners and fruit growers in Britain. Grand crops have been grown, and doubtless will in the future be grown where this practice is intelligently carried out—indeed, some of our foremost fruit growers consider their success in producing good crops annually is largely due to their systematic attention to summer pruning, and yet I am personally acquainted with several fruit specialists who do not prune or pinch their bushes or pyramidal trees till early autumn.

Notwithstanding this, the fruit they stage each year at the metropolitan shows frequently, I might almost say invariably, obtains the highest awards. Let me, however, hasten to add that I would not, on this account, advise anyone to discontinue their usual practice in cases where such has proved satisfactory, as there are, and I think always will be, instances where the shortening of shoots in summer is productive of the best results. Those who do without it so successfully are usually located in warm, sunny positions, and have the branches of their trees very wide apart. These two circumstances, taken in conjunction, solve the apparent enigma.

The majority of gardeners have to deal with established trees, planted in many instances too thickly, the main branches also being placed too closely together. When the trees are young matters may of course be considerably improved by the removal of some of the branches, but with old ones this alone will not have the desired effect; yet by judicious summer pruning highly satisfactory results can be and are obtained. Then, again, in the case of trees trained to walls, the removal of shoots at midsummer is quite necessary to allow the fruit as well as main branches to get the full benefit of sun and light, otherwise the colour, if not the size of the fruit, is affected.

Given two equal amounts of wall space to experiment upon by practising summer pruning on one portion, and neglecting it on the other, I am firmly convinced the results obtained would be to the advantage of the former practice.

Having now advanced some reasons why the work under notice should be performed, I will proceed to deal with the practical part of the matter, and leave to those who choose to take up their pens the simple task of demolishing the arguments I have set up.

In one direction we seem to have gradually altered our practice with advantage, for the work of summer pruning is now usually performed at a somewhat later date than formerly, and the extra amount of freedom given to growth in its active season is to my mind beneficial to the trees, which seem to require some channel for the overflow of their exuberant energies. When the shoots are pinched in a very young state a good deal of secondary growth is made, which necessitates the expenditure of extra time in its removal, and there is also some danger of the basal buds starting; whereas, when the work is deferred till July, or early August, those who watch trees closely will have noticed that growth is almost, if not quite, completed. The shortening of the shoots then has the effect of helping to plump up the basal buds, while at the same time but few young growths are started.

In carrying out work of this description the right course to pursue is to go over the upper parts of the trees first, shortening back the remainder of the shoots about ten days afterwards. Trees so treated do not receive such a serious check as when the whole of the growths are removed at once, and, moreover, the practice of annually pruning the uppermost portions of trees first has the effect of forcing the sap into the lower branches, thus preventing their becoming unduly weak. This is an important point to bear in mind, for it is the principle upon which well-balanced trees are produced.

Apples, Pears, and Plums require little difference in their treatment. The shoots of each should be shortened back to three or four leaves, not counting the pair of small ones at the base. On well managed trees numbers of sturdy shoots having four or five leaves will be formed. These should not be shortened, as they form fruitful spurs from which some of the finest fruit is obtained. The extremities of all branches, where there is room for extension, ought not to be shortened, but when they have covered their allotted space shortening rather severely must, of course, be resorted to.

In the treatment of young trees, well placed shoots must be selected and laid in full length to form the necessary number of branches. In old ones gaps sometimes occur through reason of branches dying. Strong shoots should in such cases be, if possible, originated and allowed to grow without being stopped or shortened for filling the vacancies. In some old trees the spurs are much too close together, which causes them to produce a thicket of shoots, not strong ones, but mere breastwood. The best way to deal with such is to cut out half the spurs at once instead of waiting till the autumn; thin the shoots on those left, and allow the others to go unshortened till September. The wood then becomes hard and ripe, and in the course of another season develops fine fruit buds.

Peach trees will, of course, already have received much attention in the way of disbudding and nailing. All that needs doing now is to pinch a few of the strong shoots, and where there is room lay in laterals from them. This will help as quickly as anything to bring them into a fruitful condition.

Morello Cherries ought to have young shoots laid in full length about 4 inches apart, the remainder being cut clean away. It will be safe to say that all kinds of fruit trees and bushes which are crowded with growths now, forming something like a thicket, may be greatly improved by a free, yet judicious, thinning of the branches, removing the more weakly or least promising, and those retained will be materially benefited by the greater amount of sun and air thus having access to the foliage. As a rule, and broadly speaking, too little thinning and too much shortening of the branches of fruit trees may be noticed, a practice that is certainly not conducive to bountiful crops of any kind of fruit.

The above are a few simple hints for the guidance of those who need them, and by acting in accordance therewith no one should have the slightest difficulty in practising usefully the art of summer pruning.—H. D.

PRECEPT AND PRACTICE.

Parting Words.

(*Concluded from page* 70.)

Looking back over many years, "remembering a thousand things that passed me on those golden wings which Time has fettered now," in order to conclude these remarks to those who are looking forward, one is impressed by the fact that there are some truths which need experience more than reason to confirm them. Young gardeners of a past generation never had the opportunities now presented to their successors for self-tuition and advancement. Visible as this is, it is, perhaps, less easy to perceive the ban which lurks near every blessing, and is ever ready to neutralise it. But, really, in one sense, young gardeners of to-day are neither better nor worse off than their predecessors, unless they feel the corresponding responsibility attached to the great gifts within their reach.

Within their reach? Ancient history tells of an old Greek who cut the wings of his bees and placed before them the finest flowers he could gather in order to save them the journey to Hymettus, yet found they made no honey. So simple is the moral conveyed, that it is hardly necessary to say it does not apply directly to our expert pupils, but, rather, to younger students whose untried wings oft weary in the first flight to our Hymettus; hence the highest teaching, the best exemplified practice, scarcely including these minor efforts, can avail but little without unceasing labour to acquire knowledge, or personal practice to attain individual perfection. We may, in the main, agree with Lord Chesterfield, that "There never were, since the beginning of the world, two cases exactly parallel;" and in doing so, may add that, practically, there never will be. In this consists one of the chief charms of life, particularly our lives, to feel and to know that in assimilating the precepts and the practice contained in those rich stores, garnered by great gatherers, such will eventually be stamped by the impress of our individual character, and moulded to each particular use.

But lately, in discussing a matter with a gentleman, extraneous to our vocation, and upon which he had received professional advice from an expert, he said, Mr. —— not only explained the *pros* and *cons* in a clear, practical manner, but he inspires one to action. We may find similar cases in our own field of work—men who, not by their knowledge alone, but by their energy and unquenchable enthusiasm, inspire those of congenial tastes with kindred feelings. These are men amongst men, and we cannot over-estimate the great influence they wield for good, or question their undoubted position as leaders. True, a direct personal acquaintance with them may seldom be our privilege, but we find their second self in their writings, and here Lord Lytton's aphorism admirably expresses what a whole page of mine could less ably convey—viz, "It is not study alone that produces a writer, it is intensity." Intensity! not knowledge alone, but that fire which warms all within its influence into vigorous life and action.

To the industriously disposed nothing is more catching than industry, is the sum and substance of an old precept, and another tells us that, "Who conquers indolence conquers all the rest." As a rule from the vitality of youth springs a desire for action, which requires but direction and confinement to its proper channel to accomplish the best possible according to individual calibre. If youth could know what age requires in the matter of character-building doubtless the foundations would be more carefully laid, and there would be less shoring up with pillars of excuse in after life, with fewer tumbles. Man was born to rule—"to have dominion," but to rule he must obey infallible laws of system, method, harmonious in their working, inevitable in their results. There is no youth, I suppose, who can realise the dynamic force of this moral in its entirety. We see some of brilliant intelligence taking erratic flights in their course of study, aiming at many marks, but hitting none decisively. Clever, and wise, and witty in their way; each and all by turns but none for long. Marvellously busy, wonderfully energetic in their movements; in fact, a combination of good qualities—of atoms in violent activity, but wanting cohesion—system—to resolve them into solid bodies. So is this energy finally dissipated into the cosmic dust of wasted opportunities.

Double toil and trouble have those who ignore Heaven's first law of order. Let no busy youth ever deceive himself into assuming that he can accomplish more than one-tenth of what he is capable of without mapping out his course of self-tuition intelligently and judiciously, according to the circumstances in which he is placed, and persistently carrying it out to the end. Our youths must soon take their place as men—men of the world, not quite in the sense, perhaps, in which that term is usually employed, so we will change it to men in the world, and not as cyphers, which are well enough for totting up a census paper. What preparation is now being made for it? As a free man with the passport of education,

or is the birthright to be bartered for a few petty frivolities with a dash of desultory unfinished things thrown in, resulting, in some cases, in a life's regret, or in others—the worst cases—into the slavery of a distorted vision, which sees the whole world going wrong with some vague notion of setting it right by the impotent lever of a blind and biassed mind?

In conclusion, my sentiments, drawn from experience of life, are clearly expressed by one who said, "The longer I live the more certain I am that the great difference between men, between the feeble and the powerful, the great and the insignificant, is energy—invincible determination—a purpose once fixed, and then death or victory." Mark the sequel extracted from the above by another teacher, "That quality ('energy—invincible determination') will do anything that can be done in this world, and no talents, no circumstances will make a two-legged creature a man without it." Success is heartily wished to all earnest aspirants by—AN OLD BOY.

BURNT EARTH.

Do gardeners, as a body, fully appreciate the value of a large heap of "burnbake?" I think not. I admit that this material is most efficacious when applied to soils of a tenacious clayey nature, but it is also of good service in improving soils of a lighter nature. It is not of ballast or hard burned soil that I am thinking; but even this, if not too coarse, may be employed to good purpose on strong clayey soil, though it is poor stuff for fruit trees and vegetables when used in excess. For genuine burnbake fruit tree roots, especially those of the Vine, have a great partiality, while the borders in which it has been used are the most abundantly tenanted with root fibres and the last to become soured.

It once fell to my lot to have to move a large vinery a distance of three miles, and in order to have "something to show" the same season all the Vines were transplanted. About one-half had apparently been treated to a heavy surfacing of burnbake, and these moved remarkably well, actually ripening a full crop of small bunches within four months of removal. The remainder had long naked roots with few or no fibres, and these, although they grew fairly well, were not equal to maturing any bunches. Much the same results have been observed when dealing with Apricot, Peach, Pear, and other fruit trees. One of the most profitable crops of Strawberries I ever grew was produced by strong plants lifted, after the fruit was set, from an open border in which burnbake had been mixed. It is practically the same when charred refuse is mixed with soil in which a variety of hardy plants are temporarily bedded out.

Private gardeners are so accustomed to use sharp sand in potting composts that the fact of charred refuse answering equally well, if not better, is lost sight of. Especially is it to be commended when the loam used is deficient in root fibres. Given the choice of either light, spongy turves and silver sand, or a fairly free-working clayey loam from a cultivated field, I should probably "plump" for the latter. Quite recently I was offered 50 loads of turf from a black soil almost for the cost of hauling, but declined it.

The compost for about 3000 Chrysanthemums I grow consists of clayey loam carted from an open field, leaf soil, bonemeal, horse-droppings, and burnbake, and if they succeed as well as they did last year there will be no regret that the loam had no fibre in it, or that no sand whatever was added. Pelargoniums, Carnations, Bouvardias, Arums, Cyclamens, Primulas, Ferns, and a variety of other plants, all have burnbake mixed freely with the soil, and those who like to see Cucumber roots in a network should try the effects of charred soil and ashes. Some fifteen or more years ago Dipladenias were shown in greater perfection than now, and I shall not forget a house the whole roof of which was draped with choice Dipladenias at their best. Among other hints the successful cultivator gave me was one upon the employment of charred soil in the potting compost.

It is at this time of the year when rubbish accumulates the most rapidly in gardens, that a slow fire ought to be started with a view to converting much of this unsightly accumulation into valuable matter. Everything that will burn either slowly or rapidly should be roughly separated from the rest preparatory to burning. Start a fire with old Pea stakes or coarse dry wood of any description, on this disposing first the drier portion of the rubbish, following with heavier greener materials, banking over with the half-rotten weeds and soil. A slow fire is essential to the successful production of a valuable residue, no flame being allowed to break through. Instead of leaving the heap of charred wood, soil, and ashes exposed to all weathers, as is often done, I advise that it be stored in the dry, as when much exposed to rains some of its manurial virtues are washed away.—W. IGGULDEN.

VEGETABLES FOR HOME AND EXHIBITION.

ROOT CROPS—ONIONS.

No vegetable holds out greater possibilities to the grower for exhibition than the Onion, and, as is well known, bulbs varying in weight from 1 to 3 lbs. are staged by eminent growers at the most important shows. For the excellence of the exhibition Onion of to-day first thanks are due to the enterprising firms of seedsmen who have looked ahead, and seeing there was capital in the bulbs have centred much of their attention on it, with the result that many excellent strains have been produced. Pedigree horses and cattle have been known for a long period, but pedigree Onions sounds somewhat paradoxical, seeing they are of quite recent introduction; yet such is the name given to the best exhibition strains which are sold in sealed packets direct from the hands of the specialists, to whom they owe their origin.

Credit also is due to growers—gardeners who make vegetables their strong forte. They have not been slow to grasp the fact that to produce Onions of exhibition size and quality a good strain is indispensable, and having obtained the approved varieties have brought energy and experience to bear on their cultivation, the result being seen in the enormous bulbs which the average Onion grower looks at and marvels. There is no trade secret about growing large Onions. Anyone can do it who has the inclination, with cultural aptitude and facilities. Special treatment is of course necessary, and if this is given in conjunction with that indispensable item to true success in all gardening operations—close attention to details—then Onions may be grown in most gardens worthy to occupy a place on the exhibition table, and if not first prizewinners they may still be a credit to the cultivator.

Those whose aspirations lead them to the cultivation of exhibition Onions should remember three rules necessary to success. In the first place, a suitable soil, as all are not conducive to the welfare of the bulbs; secondly, as I have already intimated, seeds from the best stocks that can be obtained; and thirdly, the plants must be well cultivated, and receive constant attention at the hands of the grower from the time the tiny bulblets are formed till they have reached the maximum size and are removed from the ground. A soil in which clay predominates is not good for the plants, yet they must have something substantial in the way of compost. The benefits of deep cultivation should also be observed, and the intending exhibitor must select his ground in the autumn, trench it to the depth of 2 feet, and place in the bottom a good dressing of farmyard manure. Wood ashes, soot, and lime may also be incorporated with advantage. Some growers ridge up the soil only, thus laying it open to the influence of frost. For the ordinary crop this is often all that is necessary if the ground is in good heart, but it must be borne in mind that if exceptional bulbs are required the soil must be rich in character and friable in tilth.

The brevity of our summers prohibits the full development of the bulbs if the seeds are sown out of doors in the ordinary way, therefore artificial methods are adopted by the enlistment of the services of a cool house or vinery in which the canes are resting. Propagating boxes form good receptacles for the seeds, which may be sown in ordinary potting soil in January or February. When the plants have grown to the height of 1 or 2 inches they are pricked about 3 inches apart into other boxes, and placed close to the glass in a house in which a genial temperature can be maintained. Care is taken that they do not become drawn, and hence weakly. When growing sturdily, and about 6 inches high, they are gradually hardened and given the accommodation of a cold frame till about the third week in April, when, if the weather is favourable, they are transplanted in the drills, allowing a space of about a foot from plant to plant. It is a good plan to arrange the bed so that there are two rows of Onions, and then a path, by which means all cultural operations may be performed without treading among the bulbs. It should be borne in mind that during the preparatory period the plants are subject to attacks of mildew, so that any neglect in ventilating and watering materially affects the after welfare of the bulbs.

Constant attention with abundance of stimulative food are the chief requisites through the summer. The surface soil should be frequently stirred during dry weather. A light dressing of soot and an approved chemical manure may be sown broadcast every three weeks or so, preferably in showery weather, and if dry then it must be washed in. Liquid manure from the farmyard may be used with advantage, and the moisture is conserved in dry weather by a mulching of well-decayed manure. In periods of drought a light top-dressing of salt is good. The plants must be allowed the full benefit of the sun, as the idea is to build up the bulbs thoroughly sound and hard, hence the necessity of soil containing an average amount of mineral matter. Do not remove the bulbs till the foliage ripens and dies, as this is an indication

of maturity. A cool dry shelf is the best place for storing exhibition bulbs.

Onions treated in the manner described do not suffer materially from attacks of the maggot, as the growth is firm before the plants are placed in the drills, and the dreaded fly passes them over in favour of the tender growths of the maincrop Onions sown outdoors. Where the grub is very destructive it is a good plan to sow largely under glass, and afterwards transplant, as this is a good means of averting the pest. A further method of prevention is found in spraying at intervals with a mixture of soapy water containing a little petroleum, but the first application must be given *before* the winged enemy is out and about, the time of emergence depending on the weather.

Among the varieties of Onions now in the market Ailsa Craig retains its popularity as one of the best of the large globular types. As a maincrop Onion it has no superior, and if not sown too thickly and afterwards judiciously thinned bulbs of good size and firm in texture may be obtained. Cranston's Excelsior is another variety with a reputation second to none. It is regular and even in shape, large in size, and weighs well. This variety, like the foregoing, is excellent for growing in quantity, and without any special treatment gives excellent returns. Cocoa-nut is good when its qualities are fully developed by special cultivation. Advance is also a fine Onion, and for long-keeping qualities the Improved Wroxton is excellent. The bulbs are large, even, and so sound that they will keep in good condition till the following summer.

Among the large flat types Anglo-Spanish still holds its own both for exhibition and also as a maincrop Onion. Under special treatment it grows large in size, and is perfectly sound. Both Lord Keeper and Rousham Park Hero are excellent for exhibition, and splendid examples may often be seen at large shows. Sutton's A1 is an Onion of excellent quality, and mention may also be made of Royal Jubilee as a good exhibition variety. No vegetable gives better returns for good cultivation than the Onion, whether for show purposes or general crop, so that the above remarks will be found applicable in either case.—Grower and Judge.

OLD ROSES AND NEW CARNATIONS.

An Old Rose Hero.

"Growth such as I never had before; blooms—ah! there was nothing to touch them in my showing days, and never an insect anywhere. Come and see." That closing adjuration is quite Cannellesque to be sure, and the ingenious reader who spots his man with a certainty is doomed to confusion. It was not the old lion of Swanley, but a rare fighting hero for all that, though he now talks as one who scents the battle no more. I picture him standing at the vicarage door, gazing with a pathetic far-away look as though all too sadly conscious that he is much given to forgetting the faces of friends, and pleads the weakness of sight consequent on a heavy burden of years as his excuse if he is deficient now; but his wrinkled face breaks at length into a cheery smile of recognition, and perturbation passes swiftly away. He is upright as any guardsman, notwithstanding that he bears the burden of seventy-five years, and his step has the briskness of youth. I ask myself, as I follow him, whether it is because he is leading me towards the flowers that his movements are thus buoyant. I think it must be so, and that the light in his eye is also a reflection of olden fires. Curious it is to note, and pregnant of the depth of sympathy that exists between a true flower lover and his plants, that although the veteran has to peer long and earnestly to make sure of the face of an old acquaintance, by some strange power he is able to name at the briefest glance scores upon scores of varieties, differing from each other, many of them, by only a faint shade of colouring. So do we know that love indeed rises supreme over the weakness of the failing senses.

The old hero lingers amongst his beds, pointing with joyful finger to noble blooms and thick leathery leaves. "Times have changed," he says, "and I cannot afford to keep a gardener now, for I am very poor." There are evidences of this, alas! in plenty; but as if Nature were determined to deal kindly with the old man, fly and blight have spared his bushes as they never spared them in the days when a gardener pursued his daily round of labour. They have been perforce neglected, but they are as clean as if no pestilent foe existed. And the flowers are fit to fight any cup battle. They are of huge size and full of the most lustrous colour. "I have grown Roses all my life," he says, "but they were never like this. Look at that Souvenir d'Elise, look at that Innocente Pirola. It is an old favourite of mine, but I have never had it like it is this season. Madame de Watteville, too, and Dupuy Jamain. Do you not think that A. K. Williams would have won me a medal?"

It is the same round of delighted exclamation and admiring response, long continued. Such Roses would satisfy the eye of the most critical expert, and he would be lacking in sensibility indeed if he did not see in the glory of the flowers a great and moving compensation for the burden of infirmities which time inexorably brings. It is show day in the neighbouring town, and for the first time in his career as a Rose exhibitor the venerable vicar is not there, the early morning rise and drive being now beyond his strength. But if that brings, as bring it must in the memory of past delights, a shadow of pain, this rich and bountiful harvest of flowers beguiles the sadness. It is thus, surely, that we learn the full measure of compensating happiness which the garden can bring.

Anon the veteran's knife flashes out.

"You are going to give me a lesson, Mr. Buchanan?"

"In making cuttings—yes!"

He tells me that he has had great success with own-root Roses, and shows me vigorous bushes raised by his own hand a year and two years ago. They are amongst the best of the whole beautiful flock, running over with exuberant strength.

"Now this is the secret of it all. A shoot taken off with a heel; remember that always, with a heel, taken 8 or 9 inches long and put in firmly nearly to the top."

His listener had heard the lesson before from other lips, and illustrated by other hands. Aye! and he has proved the soundness of it, but none the less he follows the movements of the deft fingers as they shape the shoot with the interest of inexperienced youth. It is no worthless method of growing Roses, this. Not every variety succeeds alike on Manetti, Grifferaie, and Briar, and many a good Rose gives of its best and freshest when it has no caterer but its own inherent vigour. Anyway, there is significance in this fact of a veteran grower, and literally the hero of a hundred fights, telling you with all the emphasis of firm and well-proven conviction that the own-root plan has his strong allegiance.

The Carnation Man at Home.

It is at the other end of smiling Kent. Town is very near, but there is only the smell of Heath and Bracken on this burning July day. Hayes village is making merry in good old English style at the annual show, and on the ground I come upon a short, sturdy figure, bearing about it a notable stamp of decision and determination. It is the famous Carnation man, he who in a few short years has achieved a distinction that falls to the lot of few gardeners. It is not a far cry to the garden, and the grower is in a mood to act as guide. The flowers are there in thousands. I ask him how many, and he tells me that there are 10,000 in pots and another 30,000 planted in the open ground. What a legion! And every variety a selected one. In all the vast array there is not one which held a place ten years ago.

It is rich enjoyment to wander through house after house. When you have seen Banner you think that anything further in rich bold colouring it would be impossible to get, and yet but a yard away you find Endymion and know that the impossible has been accomplished. This is a classic flower. It has all the parts of a really great self. In the wonderful breadth of its magnificent petals, in their firm, stout texture, in the extraordinary fullness, richness, and vividness of the colouring there are united in a most uncommon degree the qualities that go to make up a perfect flower. If the generations as yet unborn are to see as great an advance on Endymion as this superb variety is upon, let us say, Raby Castle, happy should it be. Carnation lovers would find almost as deep enjoyment in some of the best of the whites. Most people would be satisfied with Adela, but only till they had seen Mrs. Eric Hambro and Pearl. It is hard to choose between two varieties like these, but the man who can afford both need never give himself that painful task. Our old friend Purple Emperor has departed to another sphere, but he will not be regretted while Bendigo remains, for this beautiful variety has splendid growth and grand colour to help it in its fight for fame. For a yellow what advance could any reasonable mind expect on Blondin? It has substance, fine form, fine colour. But in a house further on there breaks on the visitor's delighted gaze the form of Cecilia, and then he has eyes for nought else. That beautiful race the yellow ground Fancies are represented in great numbers. You think Mrs. Tremayne is the best until you see Iago, then transfer your allegiance to that arch-traitor and reap a just retribution when at length you come upon Badminton. Lady Hindlip has the deepest colouring of all the reds. It is a rich crimson, bold, lustrous and shining.

The young carnationist is a man of deeds and not of words. He walks gravely round, throwing in a remark now and then, but for the most part leaving the flowers to tell their own story. What will be his future? He is not a one-plant man, but excels in every department of a large garden. Onions proclaim his thoroughness and skill as eloquently as Melons, Peaches, Grapes, and grand

phalanxes of pot fruit trees, as healthy, as productive, and as well trained as Mr. Rivers' own. You know him, good reader, as well as if I had worked his name into every line. I ask again—What will be his future? The workers do not always come out the best in the end, but the Carnation hero has a chance that most of us would envy—and he will not let it pass.—W. PEA.

GARDEN ARCHITECTS AND ARCHITECTURE.

BRITISH gardeners may well view with pride Paxton's Palace of Crystal adorning the Sydenham Hill; familiarity with the structure can never breed contempt, although, just possibly, it may be taken with other marvels of modern skill and mechanical enterprise in a matter of fact kind of way. Yet it is but common justice to the memory of the great gardener-architect to include in the mental stock-taking now being made of progress during this beneficent reign a brief survey of the *chef* and his *chef d'œuvre*. Great gardeners had preceded him, illustrious architects left enduring monuments behind, such monuments, indeed, as are seen in our cathedrals, to testify to sublimity of conception in the magnificent realisation of design.

It is true that the Palace arose for purposes somewhat apart from gardening, and for such it has been retained; it is true that others may view it in a totally different light, but we, as gardeners, regard it as a great greenhouse, and glory in its creation by a gardener. We mark advance by marking time and the traits it has developed—stage coaches and railroads; wind and steam; candles and electricity; and, recognising the value—nay, the necessity of comparison, we must for the nonce place in juxtaposition, not the Crystal Palace, perhaps, but one of these palatial conservatories of the present with its antitype of a hundred years ago and, by analogy, acknowledge that Paxton was veritably the Napoleon of garden architecture.

There are good reasons for supposing that our illustration of a conservatory in 1797 is an example of the best then existing, a noted gardener of that day thinking it worthy to adorn, as a frontispiece, a comprehensive little work by him on gardening—viz., "The Gardener's Journal." The reproduction (fig. 17) shows that the engraver of the original has given a tilt to one angle of the roof which does not improve its appearance, and which I do not think a gardener-architect even of that day would have been guilty of. Possibly, though, the stately dame figured in the foreground is enforcing some remarks upon the point in question by displaying what appears to be a huge horse pistol, and the good old gardener, in view of possible consequences, has brought out his largest spade as a shield of defence.

We can duly allow that glass being a luxury a hundred years ago its employment for our purpose was severely restricted, but the fact cannot be ignored that no marked development of its use in horticulture took place until the man and the hour had arrived—until Paxton in three giant strides reached the pinnacle of fame as a gardener-architect on the summit of Sydenham Hill. This does not appear to have been by laborious, protracted stages. His first practical exposition of that remarkable engineering talent he displayed being the Victoria Regia house at Chatsworth, from which was conceived and brought into existence the great Exhibition of 1851 in Hyde Park, this, in its turn, being the parent of the present Crystal Palace. There are few, if any, more fitting monuments to that munificent patron of the arts and sciences, the lamented Prince Consort, to whom must be accorded unqualified honour and esteem for including among the many traits of a noble life that of fostering and promoting the magnificent talents of Paxton.

Details of the great workman and his works need but be briefly mentioned here. Mr. Paxton, born in 1803, was educated in the Woburn Free School, and entered the service of the Duke of Devonshire at Chiswick, eventually attaining to the post of head gardener at Chatsworth. Here his successful experiments with iron and glass for horticultural building led to the planning of the great Exhibition on the larger scale, embodying the same principles. For this he received the honour of knighthood ere commencing his *magnum opus*. In 1854 Sir Joseph was elected M.P. for Coventry, which he represented until his death in 1865. *Apropos* of his *régime* at Chatsworth, that veteran horticulturist and cultured scholar the late Mr. Geo. Cunningham of Liverpool told the writer there was none he enjoyed and appreciated converse with more than Paxton, and that the last time he dined with him in the gardener's house at Chatsworth there was outward and visible signs of coming events in two livery servants waiting upon them at table.

The great Exhibition, as well as it served its direct purpose, indirectly paved the way to that perfection found in its permanent successor; for, as far as the building was concerned, various defects which only experience could determine were noticed to be avoided. In the present Crystal Palace the grandeur and harmony of design are perfect to a fault, if we may say so, for where criticism finds no margin for adverse judgment it often lacks by want of comparison a full measure of appreciation. Would that by some Rip Van Winkle process the architect of our conservatory of a century since could view this sparkling triumph of iron and glass!

The writer's first impressions of this colossal conservatory were, I fear, but parallel with those of the public, whose wonder is often absorbed in the variety shows. Well do I recollect as a child seeing it first from a vantage point some few miles distant flashing back the dying rays of the setting sun, and the childish wonder and admiration which could only be appeased by the promise of a visit to it. Of that visit, which took place at a school excursion some few years after, there is but one feature prominent in memory, and that is the waiter who served up our cold collation, brought it ready cut on plates piled up sandwich fashion, and

FIG. 17.—A CONSERVATORY IN 1797.

the bulk of my moiety stuck to the bottom of the next boy's plate which he appropriated, to the end that I was a sadder boy and but little wiser for the visit. Then, I think, the next visit was engrossed by Blondin, and the next is yet to come, when, doubtless, in looking up its 174 feet to the roof of the central transept, in knowing that there are some 25 acres superficial of glass and some sixty miles of hot-water pipes, the grandeur and magnitude of its proportions will be justly appreciated.

Probably the source of Paxton's inspiration as a designer may be traced to that voluminous writer, zealous scholar, and earnest worker, John Claudius Loudon, who, in addition to his exhaustive studies and comprehensive published works upon agriculture and horticulture, grafted upon each of these great branches the study of architecture in direct relation to them. In 1805 Loudon published "A Short Treatise on Some Improvements Lately Made on Hothouses;" in the following year, in two volumes, "A Treatise on Forming, Managing, and Improving Country Residences, and on the Choice of Situations;" and in 1832 "The Encyclopædia of Cottage, Farm, and Villa Architecture." To the fertility of Loudon's inventive faculties must be attributed the "ridge and furrow" system of horticultural building, although it was left to Paxton to place it in practical form. Loudon was not destined to witness Paxton's crowning work, nor, indeed, the exhibition preceding it, his death occurring eight years previously at the age of sixty whilst actively engaged upon his labour of love, his unfinished work being "Self-Instruction for Young Gardeners."

Rude as were the earliest examples of greenhouse architecture, some of them being simply sheds, with a glazed sash introduced for

the admission of light, it was the dawn of a new era. If we view the long-ago greenhouse in the light of modern criticism, the methods of heating must be considered as barbarous. As far back as 1684, we are told by Ray, the greenhouse in the Apothecaries' Garden at Chelsea was heated by means of embers placed in a hole in the floor. Later, in 1771, in the "Medicus Index Plantarum," a sectional view of a greenhouse in the Elector's garden at Mannheim, advance is marked by a stove being shown. This was followed by the use of flues, which carry us well within the Victorian era, and some examples of which, now rightly termed old-fashioned, are still to be found. Literally and figuratively those were the dark ages of garden architecture, when struggling under disadvantages, that intense love of gardening, especially characteristic of the English and German races found, in the system of hot-water heating, the freedom we now enjoy.

Of that increasing demand and marvellous supply of horticultural produce necessarily grown under glass, which in its turn increases horticultural building by leaps and bounds, it is needless to dwell upon; sufficient to say, or rather to quote from a recent work, "Where twenty years ago one plant-house was to be seen, there are nearer fifty now," and the cry is Still they come; good, sound, sensible houses, designed on the most practical of all bases —viz., to pay. In viewing some of this building, of which the suburbs of London provide so many examples, where ten, twenty, fifty and more span-roofed houses of considerable length are to be seen *en bloc*, although the architecture is of the simplest description, the eye dwells upon them with not less satisfaction than upon the more imposing types, so admirably do they in their rigidity, lightness, and general essentials adapt themselves to their purpose.—FREEMASON.

CHARACTER SKETCHES.

BUSY MEN.

WE have received two letters from correspondents in which regrets are expressed for not sending contributions of late. It must be understood that we had no thought of making any complaint on the subject, though we are pleased to hear from both of them when they have time to write. They are young men—that is to say, were born about a generation ago, and are above the ordinary run of gardeners in educational attainments, largely, we suspect, and laudably, acquired since they left school. One of these men is more of a "dandy" than the other, and he cannot very well object to our saying so—first, because it is true; and secondly, because wild horses would not drag from us his name.

As the two letters arrived by the same post, and were, in fact, the first and second opened, we could not but observe the difference between them. They were alike in one respect, and one only. The two young gardeners had been so very, very busy that they could not find any time for the pen. If the statement had ended there no more would have been heard of the matter, but they both found just time enough to make explanations as to the pressure to which they had been subjected; and as these statements are not without significance, it might be somewhat of a pity if they were lost to the world. The first letter that was opened is in these words:—

"We have had such a busy season that writing, much as I love it, has been out of the question of late. To give an example of a week's work—Three swell dinner parties, three cricket matches, and one ball. I have had to attend all these, but I don't mind, as we won twice."

This reference to seven events in one week is perhaps a little mixed, but we may presumably take it that the "winning" refers to the "work" of cricket, of which, we understand, our smart young friend is somewhat of an adept. The other "work," we may suppose, consisted in dressing the dinner-table on three nights, and taking part in a ball, possibly after a cricket match, which *would* be a hard day's (and night's) "work," especially if it were the losing day. That all this comes within the "work" of a young gardener shows how different things are now from what they were a generation ago; still, a man must do his duty, even if he has to sacrifice the evening occupation he "loves so much"—composing essays on gardening. Let it be granted that he really does enjoy this instructive exercise, the question still may be asked—Does he "love" cricket more? In this reference, however, it may be said that skill in the "field" is not incompatible with capacity in the garden, as sundry examples prove.

These remarks, it must be understood, are not condemnatory of anything or anybody, but comparative; and here is the comparison —the second letter. It reads as if from the "'orny hand" of a son of toil, but there are brains behind the labour, as there always ought to be; and after the potting and the packing will come the pen, because this worker (not in the ball-room or with the bat and ball) tells us so as follows:—

"My work has been so heavy of late that when the day was over I was too tired to write. No one will know better than yourself what I have had to do when I say that during the past month I have potted 4400 Tomatoes in 12's, and 1100 Chrysanthemums in the same size; also 2000 Royal Sovereign Strawberries in 32's; and besides all the watering and tying, packed 4 tons of Tomatoes—my first crop—my only help being a labourer; but now that the heavy work is finished I shall soon be at the pen again."

It will be conceded that the two letters are different from these two men, each able in his own way; and it may perchance be granted that they ought not to have been consigned in silence to that receptacle of random thoughts known as the W.P.B., because they will give birth to other thoughts, which may, perchance, culminate in action, on lines that each particular young thinker may deem the best. We should rather like to know, also, what some of the older "thinkers" think of them—the "Old Boy," for instance, whose sympathies with striving, struggling youth are obviously so sincere—whose counsel is so wise, whose desire is so strong that the gardeners of the future shall be better than those of the past. Cannot he in the fertility of his conceptions enforce no lessons from letters so diverse, and which were never intended to see the light, as those above cited?

Character sketches, they may be taken to be, as indeed they are —types of men of whom there are many of each kind, but more perhaps of one than the other. Will there be room in the coming years for all of both these types to distinguish themselves in the world of gardening? and for which are there the greater possibilities of raising themselves above their fellows, of exalting the art of which they are exponents and enriching the world?

EXHIBITS OF WILD FLOWERS.

THE too common and utterly worthless exhibits of wild flowers set up at flower shows all over the kingdom have absolutely no merit, for whilst not one in fifty is really light and graceful in appearance, the bunches teach the little ones nothing useful. Then, too, they lead to a wholesale gathering and consequent destruction of these pretty natural products, and the more flowers are thus ruthlessly and wastefully gathered the greater are the reproductive powers of these plants reduced. It is too much forgotten that so long as wild flowers adorn our hedgerows and lanes, our woods and commons, they make in all such places gardens for humanity at large. No feature is so noticeable and so lamentable in the neighbourhood of large towns as is rapid disappearance of wild flowers, destroyed by reckless and ill-advised plucking.

Those whose duty it is to judge such exhibits as nosegays or bunches of wild flowers present at shows, realise almost their impotence to decide as to the merits of such products, and when shown, as is sometimes the case, in hundreds, the task is almost an appalling one. Against these wild flower bunches I have often written and spoken most earnestly, because they are worse than useless.

On the other hand I have strongly advised that wild flower exhibits should be of an essentially educational nature, the children who present them being wanted to stage so many kinds or varieties, in small bunches, neatly set up in glasses, each one being correctly, or so far as possible correctly, named both with the botanical and common appellation. Some children know the common names of wild flowers as they do those of wild birds; but even that knowledge is both limited and imperfect. Still, whilst a general knowledge of such common names is useful, it helps little to a better knowledge of or appreciation for these wild flowers. It is when children are not only taught the family or botanical names of wild flowers, but to thoroughly understand them, that real interest is aroused, and what was in wood and hedgerows before a sealed book, into which not the least care is shown to look, now becomes an open volume, which is read with the deepest interest.

I have often urged that not only should the present absurd wild flower classes be withdrawn, but also that the prizes be given only to named collections culled from the district; and, still farther, that persons of leisure, ladies especially, who have, or for the purpose would acquire, botanical knowledge, should form children's classes, and during the summer evenings or on days when there was leisure take these round the locality to collect plants or flowers for naming, and in that way not only find very delightful occupation, but also spread abroad such wide knowledge of names, habitats, and families of wild flowers as would speedily transform numbers of children from being mere dullards or drones into intelligent, devoted lovers of Nature, and especially of wild flowers.

I met with a very interesting feature at a recent village flower show in Petersham, near Richmond, where the Rector, the Rev. W. H. Oxley, all honour to him, had offered to boys under fifteen years of age, and girls in a separate class, capital prizes for the best collection of wild flowers set up in separate bunches, and so far as possible correctly named. There were several large collections staged, the numbers of diverse kinds ranging from twenty to fifty. The nomenclature was very fair, not a few being botanically correct, whilst many others had their common appellations only. All praise to Mr. Oxley for what he has thus done, and it but needs the friendly coaching of some lady or gentleman to render these classes of immense value to children generally. —A. DEAN.

ROSES

MEDEA AND MARÉCHAL NIEL.

I HAVE just received the following communication from one of the greatest of British rosarians, who gives me permission to use it in any way I please :—

"I do not know whether you will think well to answer the communication which appears on page 100 of the *Journal of Horticulture*, but it certainly seems to me that the correspondent has overstated the case as regards the fitness of Maréchal Niel for outdoor culture. Such an instance as 'W. R. Raillem' quotes must be quite exceptional, and in ninety-nine cases out of a hundred the most intelligent pruning can do no more than get a single crop of flowers, and these almost invariably become damaged by the weather before attaining perfection unless growing against a wall. No amount of writing can truthfully represent Maréchal Niel as a satisfactory garden Rose, whereas Medea is one of the best outdoor Roses of its class and colour, as witness the splendid flowers of it that have been continually shown this summer by Mr. Orpen of Colchester and others."

I hope to find other rosarians giving their opinion upon this interesting subject.—DAVID R. WILLIAMSON.

"THE QUEEN."

I WISH to propose a toast, my friends, if a lady may. Full of days and crowned with honour, blessed by her people and made a blessing to them, it is not of her Gracious Majesty Victoria of whom I would descant, but of a frailer sovereign who comes to us in radiant beauty each summer, and only leaves us with the first frosts of winter. Rosa regina, of her I would sing, had I the gift of the poet. Rosa regina, in all her moods, in all her protean forms of loveliness. She condescends to expand her beauties alike in the cottage garden as in the wide domains of a ducal owner.

You may think you know the Rose intimately, but you must have spent every summer of a long life in her company to say so with any degree of truth. Of course a nurseryman's knowledge is unique, but personally I think the best way to acquire an "at homeness" with her majesty is to be the owner of a fair-sized garden where the Rose is made a special feature. In a nursery everything is too neat and trim—*i.e.*, rows upon rows of each variety with no break or tangle of other flowers to serve as a background or contrast. A smooth-shaven lawn makes the fairest setting and walls of greenery, Yew for choice. What makes up the charm of so many gardens seen in the Academy? Masses of red, white, and blue, varying in height and toned down by vistas of grey green.

Very few people, except her own particular worshippers, see Rosa regina at her best. She is not a flower for midday exhibition—her beauty is too rare, too delicate for a full blaze of sunshine. It is said that only a perfect style of loveliness can bear the light of the early morning sun, so if you will rise with me betimes I will show you such a picture as will make your heart sing for joy. The sun has just left his bed, and the shadows from the old grey house fall athwart the western lawns; the birds are awake—the day is never too long for them—but little else is stirring. Dew everywhere; the poor flowers, full blown by yesterday's sun, have drawn in and stiffened their drooping petals, and for an hour or two will flaunt it again with their young fresh sisters The cool air and the bath can do so much to re-invigorate the failing, and what must the effect be on the newly opening flowers? Strong shoots uninjured by the mild winter have been tied in one to another, and form a succession of rosy festoons, the wealth of Roses, so heavy as to fairly cause the arches to reel and fall forward. What shall we look at first?

The hedges of Félicité Perpetué, Ayrshire Ruga, and Crimson Rambler—Félicité with her clusters each a perfect posy, the central, or mother Rose, of the purest white, and compact in form, with her attendant mass of pink children in various stages of development. Her leaves are of a glossy green, and her sprays of this year's growth of fairy-like elegance. "Ruga" is a modest flower, bends her pink-tinted face, and sheds a sweet perfume around. Here is the sturdy Rambler—of such a crimson! and lifting his handsome face to catch every beam of light. A heavier climber you see in Cheshunt Hybrid, big flowers, big leaves, for about two days unsurpassed in colour—then, alas! fading to a dingy magenta. Here is an old pink Monthly, and by her side Mrs. Bosanquet with fair and delicate blooms. Here is a flower, upright as a dart, firm and strong, in the middle of a setting of perfect green, cup-like, and of a lovely pink, but, alas! scentless—our old favourite the Baroness, and in close proximity what might be her sister in white—Merveille de Lyon. A pretty Tea, often the best in a box of exhibition Roses, is found in Catherine Mermet, and near her, with creamy pink, is Marie Van Houtte—a soft primrosy yellow at her zenith. she blushes rosy red as she gently passes away. Here is some size and vigour too, with perfect shape. Look over the plants—not a single failure. Mrs. John Laing does credit to her raiser, and her fair pink is set off to perfection by the richer hues of her German neighbour, Ulrich Brunner. Go to that tree when you will, there will always be a flower, the best of its kind. Where is there such a rich red as marks the Queen's second son—he of Edinburgh, or so dark a crimson as Prince Camille de Rohan—alas! a hot sun fairly browns and burns his deep petals; he is eminently a Rose for bad weather.

A year or two back, in all shows, Madame Gabriel Luizet took first place as a pink. She seems to have been relegated to an inferior position, but grown as she has grown this summer she is bad to beat. Do you want anything fragile? Sweet Madame Cusin, with her pinky rose petals, like a butterfly's wing, or the fair white flowers of Alba rosea. Ask for a deeper shade of salmon pink, and I give you Madame de Watteville, a full blown Rose on every stem. It hardly pays to grow a Rose that only flowers to perfection, say, once in nine years; but Etoile de Lyon, with her daffodil yellow and red-green foliage, is worth growing, even on those terms. For an exhibitor of Teas, there is Cleopatra, as enchanting as her Egyptian namesake, with her big long-pointed bud, and Souvenir d'Elise, so strong in petal that she may and has been carried to three successive shows (hot tents and the toils of travel), and taken first in each instance. For richness of fragrance, beauty of shape, with her petals turned back, nothing has been found yet to touch old La France, and she too is constant in season and out. Running her close for scent is Boule de Neige, a curiously shaped Rose of the purest white, and with dark foliage. Among the other pinks, but differing as so many stars, are Marie Finger, Captain Christy, Egeria, and Lady Mary Fitzwilliam.

Do you know the warm flesh tint of a young baby's skin? Look at this loose petalled Viscountess Folkestone and see the close resemblance. There is another Rose, equally delicate in tint, but more cup-shaped and closer in habit, the pretty Cannes la Coquette, and Violette Bouyer would come in a good third. Of dark Roses their name is legion. In a decently managed rosery do you ever see a really bad Marie Baumann? I never do, and Charles Lefebvre is ever an old favourite. Fortune's Yellow, with her masses of golden bloom, alas! like fortune, is often fickle; but when she does bestow her favours, it is with a lavish hand. I wonder if Victor Hugo was ever so sweet and lovely as his namesake, and a W. A. Richardson in the flesh would need treatment for a sharp attack of jaundice.

No garden is complete without a Sweetbriar or two, and Lord Penzance, now that he rests from his legal labours, has done much for their improvement. I have still a lurking tenderness for the sticky Moss Rose of my childhood. Do you know its sharp pungent odour? The little Scotch yellows, the first to bloom of all this vast family, are perfect in their way, and make such glorious masses of colour in the garden at a time when colour is so wanting.

I cannot catalogue like a nurseryman, nor have I the ready and trained pen of a "D., *Deal*," a "W. R. Raillem," or a witty Dean of Rochester; but I do love my sweet flowers, and it is out of the abundance of the heart that one must speak. Never have they been so lovely or so abundant as in this glorious year of Jubilee, and it is but a fitting tribute that the greatest queen that ever lived should have her path strewn with wreaths and garlands in lavish profusion woven out of this regal flower. —THE MISSUS.

COMMENTS.—THE NORWICH SHOW.

AS a national society, the committee which manages its affairs is bound to make arrangements for exhibitions to suit its members in all parts of the country, and it falls to its lot to make geographical distinctions which are sometimes called in question. Why, it was asked three years ago, was Gloucester fixed on for a Southern show, and only this year Norfolk for a Northern one? Someone (I suppose waggishly) said, "Oh! of course, as the first three letters of Norfolk evidently designate something northern." East Anglia had, however, for a long time called out that it was neglected in our arrangements; so after communication with the Norfolk and Norwich Horticultural Association it was determined that the Northern show for the present year should be held there under its auspices, which has for many years been affiliated with the National, and is evidently well officered and managed. In one respect local exhibitors had cause for complaint. Their own show is held in the first week of July, and to put it off for a fortnight was, of course, a great tax upon them and their Roses; moreover, from many parts of England Norwich is not easy of access. Of course, the Southern amateurs did not expect to be present; the show by its date was intended for northerners, while the East Anglian contingent was in great force.

The exhibition was held in the delightful grounds of Carrow Priory, the seat of J. J. Colman, Esq. It was an extensive one, and was contained in five tents, but the one with which we have to do was a large and airy one, in which were staged all the exhibits intended for competition in the National Rose Society's schedule. The weather of the preceding week had been extremely hot and trying for the Roses; this told, naturally, more upon the H P.'s, especially upon the dark flowers, than on the Teas or Noisettes, although there were some fine flowers in all classes that were exhibited. There were, of course, few exhibitors from the South of the Thames, and Essex and Herts carried off the lion's share. Neither the North nor the northern Midlands took a very prominent place, and it was curious to see how in both nurserymen and amateurs the leading prizes went to one exhibitor in each division. Thus in the nurserymen's class the old veteran, Mr. B. R. Cant, carried off the Jubilee trophy, with all the principal prizes which he could compete for, and I think we may fairly say that to his son, Mr. Cecil Cant, is due a great deal of the honour. He evidently inherits the taste of his father, than whom no one understands better the way of setting up a box of Roses.

In the amateurs' division Mr. E. B. Lindsell swept the board, carrying off all the principal prizes, and now holding both the trophies for the present year. It has always been felt that as far as H.P.'s are concerned he was always almost unapproachable, but I think it must have been a surprise to many that he should have taken the prominent position he did in the Tea classes. He has always shown some good Teas in the mixed classes, though in the Tea and Noisette division he has not heretofore taken a prominent position, and now East Anglians and others will have to count him as a very formidable adversary in this division. Scotland was altogether unrepresented, as the list of the counties given by Mr. Mawley shows, nor did any come from Ireland, as Messrs. Dicksons did not exhibit. There were, of course, many exhibitors from Norfolk, but these were mainly in the local classes.

The two stands which stood out most prominently were those exhibited by Mr. B. R. Cant, for which he gained the challenge trophy, and that shown by Mr. E. B. Lindsell, to whom also fell the Jubilee trophy. In the former stand the most noticeable were of H.P.'s A. K. Williams, Madame Charles Crapelet, a very old Rose; Beauty of Waltham, which, though sent out in 1862, still holds its own as an exhibition Rose; Susanne Marie Rodocanachi, Duchesse de Morny, Marchioness of Londonderry, and Countess of Rosebery; while amongst Teas were Comtesse de Nadaillac, which seems to be good everywhere this season; Muriel Grahame, Innocente Pirola, The Bride, and Catherine Mermet. Messrs. Harkness & Sons were a good second, and some of their darker coloured flowers were of very great excellence; while Messrs. Paul & Son made a good fight for a third place.

Mr. E. B. Lindsell is so good a grower and exhibitor that we may be sure to find the very best Roses in his stand. We find him still clinging to the older varieties, and in his box were good blooms of such old-established favourites as A. K. Williams, Marie Baumann, Alfred Colomb, Beauty of Waltham, Souvenir d'Elise Vardon, Madame Victor Verdier, Merveille de Lyon, Her Majesty, Charles Lefebvre, Horace Vernet, and Duke of Wellington (not very often seen now). Rev. J. H. Pemberton was a good second; in fact, these two champions run one another very closely. Last year it was Mr. Pemberton's turn, and this year it is evidently Mr. Lindsell's. Mr. Lindsell's twelve Teas were very fine; with the exception, perhaps, of Maman Cochet they were all old-established favourites; indeed, it will be some time before such flowers as Comtesse de Nadaillac, Catherine Mermet, The Bride, Innocente Pirola, and Madame Cusin are supplanted. It was noticeable, too, as showing that distance does not form an insuperable barrier in the successful exhibition of the Rose that Messrs. Townsend of Worcester came from the extreme west, and carried off the first prize in eighteen trebles; the flowers were wonderfully fresh, especially when the heat of the weather was considered. Mr. Orpen, who is so well known as one of our most successful Tea exhibitors, obtained the prize for eighteen varieties with an excellent stand; but, as I have said, all the principal prizes fell to Mr. Lindsell, while the Rev. J. H. Pemberton followed closely in all classes as second, and Mr. H. V. Machin as third.

In the open classes there were some excellent stands, while in that for new Roses Messrs. Paul & Son exhibited good blooms of both foreign and home-raised Roses; they were T. B. Haywood, Marquis de Litta, Sylph, Bladud, Bacchus, Alice Furon, Captain Hayward, Helen Keller, and Mrs. W. J. Grant. With regard to this latter Rose it is satisfactory to find that in no instance that I can recollect has it been exhibited under its American synonym. As it was fitting on such an occasion a special prize was offered for Her Majesty, and was taken by Messrs. Paul & Son with some grand blooms. Messrs. Townsend & Son of Worcester had some grand blooms of Comtesse de Nadaillac, as had Mr. Frank Cant of A. K. Williams. The Tea division was one of exceptional interest, for the weather suited these Roses much better than it did the H.P.'s, and in the trade division Messrs. Merryweather & Sons occupied the leading position which they have so long coveted, their stand of twelve trebles being a very beautiful one containing grand blooms of Maman Cochet, Niphetos, Madame de Watteville, Golden Gate, Catherine Mermet, Comtesse de Nadaillac, Ernest Metz, The Bride, Souvenir d'Elise Vardon, and The Bridesmaid. The amateurs' division was also very strong, Mr. Lindsell, as I have said, taking the foremost positions, closely followed by Mr. C. J. Grahame.

Garden Roses, although very attractive, were not equal to those seen either at Portsmouth or the Crystal Palace. Mr. Machin occupied the premier position amongst amateurs, and Messrs. Paul & Son amongst professionals; amongst trade-growers Mr. Chas. Turner showed remarkably well, as did also Mr. Orpen amongst amateurs. The "displays" of Roses were not satisfactory, and the strictures of a well-known horticulturist in one of your contemporaries this week are well deserved; although I cannot agree with him that the Rose is a flower that lends itself easily to decorative purposes. Of course, this sounds like heresy, but at the same time I believe it to be true.

The medal Roses deserve notice; the blooms which obtained the awards were in each case exceptionally good. The Muriel Grahame with which Mr. Orpen carried off the medal was a magnificent flower. Its comely shape, good substance, and its distinct colour contributed to make it a very lovely specimen of this variety, and surely we may say that when a Rose during the first year of its general distribution carries two silver medals at the exhibitions of the National Rose Society its claim to being a great acquisition can hardly be doubted. There are some who shake their heads and say it will revert to The Bride; but I do not think that Tea Roses are apt to return to the type. The other Tea Rose which obtained the medal in the nurserymen's class was a magnificent bloom of Niphetos, certainly the finest white Tea when caught in such a state as this that we have. I saw somewhere the other day that a writer mentioned Kaiserin Augusta Victoria as the best white Rose that we have; but I confess that I cannot see the whiteness of it, although I am quite willing to admit its beauty. The Roses which gained the medals in the H.P. class were Mrs. J. Laing, a rather undersized but a well formed bloom exhibited by Mr. S. Berger of Stevenage, Herts; while Messrs. Harkness & Son secured it amongst nurserymen for a beautiful and well formed flower of Earl of Dufferin.

On the whole, then, we must conclude that the northern exhibition was this year a successful one, and will, we hope, give a fillip to Rose growers in the eastern counties; and many thanks are due to the Secretary and Committee of the Norfolk and Norwich Horticultural Society for the efforts which they made to make the first National Show held in the eastern counties a great success.—D., *Deal*.

BRIEF NOTES ON ALPINE FLOWERS.

(*Continued from page* 54.)

ACÆNA MICROPHYLLA.

THE Rosy-spined Acæna, although comparatively plentiful in collections of alpine flowers, is yet worthy of even wider acceptance than it at present receives. Its usefulness is not limited to the rock garden or rockery, as it will be found serviceable in carpeting some borders occupied by taller growing plants or in semi-wild places where a close cover of vegetation is required. It is as widely known by the name of A. novæ-zealandiæ as by Hooker's one of microphylla, which has the priority, and is also better than the former name, there being several other species natives of New Zealand.

Acæna microphylla is of a creeping habit of growth, and is exceedingly dwarf, its height being generally from 1 to 2 inches. The pinnate leaves are of a pretty green, but the flowers are extremely ineffective, produced though they are in dense little globular heads. The beauty of the plant consists in its leaves and the bright crimson spines which so adorn the heads of flowers. These give a mass of this Acæna a very beautiful effect. It does not like a very dry position, although it will grow in such, and prefers a rather moist, peaty soil with a fair amount of sun. In the rock garden it is often found very useful for growing between the stones in rocky pathways or along the edges of the walks. It is readily increased by means of division.

CORONILLA VARIA.

We have here a plant eminently suitable for large rockwork, and quite out of place among the smaller encrusted Saxifrages, the exquisite Dianthi, and other diminutive and choice alpine flowers. The free growth, trailing habit, and pretty flowers of this Coronilla are better seen trailing over a sunny ledge of rock or covering some almost perpendicular crevice than when grown in the border, even if trained, as some recommend, over sticks so as to form a miniature tent. The name Coronilla, or "Little Crown," is a very appropriate one from the way in which its Pea-shaped flowers are clustered together.

Like most of the Leguminosæ, it possesses elegant foliage as well as graceful flowers, and these merits are enhanced by the colour of the blooms. Plants vary in the shade of the colour shown by the flowers, and the blooms themselves also give diversities of tints. The colour varies in some specimens from white to almost purple. Thus the name of "Various-coloured Coronilla" is appropriate, although the other trivial or popular one of "Rosy Coronilla" is more pleasing, and well represents the greater number of the plants grown. It will grow 4 or 5 feet in length, so that anyone planting it must allow for this feature when choosing its position. It is recommended that division of the roots be followed for increasing the stock; but one finds that young plants raised from seed grow more rapidly and are more readily established than divisions of old plants. Seeds are easily obtained, and may either be sown under glass or in the open.

It is a native of Europe and Asia—a variety, named by Boissier libanotica, coming from Armenia. It in no way detracts from the beauty of this plant to know that it has been used as a food for cattle. It is to be doubted, however, if it were found of much value for this purpose. A plant cultivated in 1597 and of value for cattle would have been more widely grown than it is now. It is as an ornamental plant that it is spoken of here, and it can be confidently recommended for this purpose in the positions already mentioned. It begins to flower in this garden in July, and continues for a month or two to produce its prettily coloured heads of bloom.

CAMPANULA PELVIFORMIS.

Botanists and gardeners do not always agree in the names of plants, and when the latter are checked with regard to an error in nomenclature they are apt to retaliate by saying, with some degree of truth, that botanists differ among themselves. The plant or plants under notice may more correctly be named C. carpatica pelviformis, but this is too cumbrous a name for general use. A plant named C. c. pelviformis is said by a high authority to be a seedling of C. c. turbinata. There are, however, several pelviform or saucer-shaped varieties, and some two or three of these approach more nearly to the typical C. carpatica than to the variety known as turbinata.

One of the best of these was received from a well-known nursery in

Chester, and it is generally an admired plant by all garden visitors Its colour is a light porcelain blue, and the habit is stiff and erect—stiff in the sense of firmness, but without inelegance. It is a little later this year than usual, and did not begin to bloom until the end of June. It will continue to flower for a long time still. This variety is increased by division. Another, and, in my opinion, less beautiful variety has smaller, darker, and more cupped flowers than this, but has the same upright habit.

A very distinct variety of more trailing habit has for some time been a mass of bloom. It is also darker, rather more so, indeed, than C. c. turbinata, and is very effective where it grows close to a narrow gravel path at the base of one of the rockeries. It is one of the most profuse bloomers among the Campanulas, a statement which means much, as those well acquainted with the beautiful Bellflowers well know. There is no difficulty in growing these varieties of C. carpatica, a light but fairly moist soil suiting them well. A slight shade from the height of the mid-day sun will prolong the flowering period.—ALPINUS.

(To be continued.)

ABUTILON CULTURE.

(*Continued from page* 96.)

FOR general decorative purposes Abutilons may be grown in almost any shape. Pyramids can be formed by stopping the lead at about every foot of growth, and the side growths to 6 inches, keeping them from flowering each year until a good well-furnished habit is attained, and then allow them to flower. It is of great importance that an equalisation of growth be attained, therefore gross irregularities must be cut away unflinchingly, seeking to apportion the vigour as far as practicable throughout all parts, having the plants as well furnished at the base as at the summit. Well grown specimens rival, if they do not excel, Fuchsias in picturesque loveliness.

Useful decorative plants are raised from cuttings of the growing points, choosing vigorous examples early in spring. The cuttings root readily in a close frame stood in a Cucumber pit, if a gentle bottom heat is afforded. They may either be inserted singly in thumb pots or be placed just clear of each other around the side of a 6-inch pot, repotting them in the latter case so soon as they are rooted, and keep them rather close until established. I prefer the single pot, and so soon as the cuttings are rooted remove them to shelves where they will be just clear of the glass. When inured to the air of the house and the pots full of roots shift into 4-inch pots, continuing in a gentle warmth and a light position until established, when they may be moved to a cooler house, but keeping rather close so as not to give a severe check. A span-roofed house or pit is best, in which the plant can have a cool moist base to stand on, and where they can be near the glass without touching it. The plants must also have plenty of space sideways, and as these make very handsome decorative plants they must be given every encouragement in the shape of a little artificial manure mixed with the first and all potting compost, and a sprinkling on the surface of the pots about every ten days, just a pinch between the finger and thumb, evenly disposing it on the surface for the waterings to carry down to the roots. Shift from 4 to 6-inch pots, and if all has gone well the plants will be ready for transferring to 8-inch pots early in June, always allowing them to fill the pots with roots, but before they become matted shift into larger pots. These—viz., 8-inch pots—are the size they are set to bloom in, and the plants being grown in a cool house in plenty of light they will branch from the base, the plants being trained with a single stem, and so be furnished to the pot, affording a fine head of bloom from at least early August right away through the autumn and winter. These plants are fine for greenhouse or conservatory decoration in late summer and autumn, and in a light properly ventilated house, with a minimum temperature of 50°, flowers will be borne successionally through the winter into the spring months.

For winter flowering I find cuttings rooted early in April, grown similar to those rooted earlier, and transferred to the largest pots not later than mid-July, the most suitable, as they will be about 15 or 18 inches in height, and coming into flower by mid-September or its close, and then placed in a house with a temperature of about 50°, they will be at their best during the early autumn and winter months. In winter they must not be overwatered, and the air of the house must be buoyant, damp, especially when accompanied by cold, being fatal to the flowers.

I have tried placing the plants intended for winter flowering outdoors in summer, with the result that though a fine full habit was secured, the plants did not flower so satisfactorily as those that were grown from first to last under glass. The moisture of late summer I apprehend made the growth too soft, and not unfrequently the soil was soaked, and the roots were killed. Some, however, manage the plants very well stood on and partially plunged in ashes during the summer months, housing at the close of September; therefore my lack of success with plants so treated may be due to inadaptibility of location.

There are, perhaps, no finer plants for bedding than Abutilons. They may be raised for this purpose by inserting cuttings early in spring, February or March, and growing them on so as to have sturdy well-established plants in 4 or 5-inch pots, well hardened by the close of May or early June. For bedding purposes, however, it is best to root the cuttings in gentle heat during the early part of September, repotting singly when rooted, keeping them in a house from which frost is excluded and rather dry during the winter. They may be left in the store pots over the winter, repotting in spring, but the single-pot system of wintering is a long way ahead of the poverty huddling method. Transfer to 5-inch pots in spring, and if the plants have become tall cut them back to about 4 inches from the soil. This should be done and the plants allowed to start again before they are potted. Encourage growth by liberal treatment, hardening them well before planting out.

Outdoors give them a sheltered situation, as their flowers are liable to be damaged by strong winds. They look best on a gentle elevation, yet are highly effective when viewed on a level or even from a height. They require a bed of good rich light soil, deeply stirred, to grow in, and made moderately firm so as to induce flowers as well as foliage, and plant them about a foot, and not more than 18 inches, apart. It is better to raise a fresh stock of plants annually than to lift and store the old ones.—A.

PEAS AT MAIDSTONE.

A SHORT time since, when examining the Peas growing at Chiswick, where true character is, because of the porous nature of the soil and the exceedingly superheated condition of the atmosphere, not always correct, Mr. George Bunyard invited me to run down to his seed farm at Maidstone, and see how Peas and Beans did with him. I could not spare time until the 22nd, by which date all the earlier varieties were ripe, and the greater portion of the main crop section were a little past tenderness.

None the less, I had an interesting visit. The seed farm is very extensive, comprising over 200 acres, and lies on the high land two miles out of the town towards Sittingbourne. The soil is fairly good, on a dense chalk base, and, of course, the air is of the freest—indeed, it is in relation to soil and atmosphere the very converse of Chiswick. I found not short rows, but rows extending to hundreds of yards in length, all properly staked, and the seed sown thinly. I often think that to see Pea plants in true character we still sow far too thickly. I have sown at the rate of one pint per 100 feet, and found from good seed that to be rather thick. I should say, judging from appearances, that Mr. Bunyard's drill made a quart reach 300 feet, which gives very different results from what is commonly seen in the thickly studded plants in gardens.

But apart from getting a good crop of fine pods, everyone familiar with Peas knows how they tend to sport, and how needful it is to preserve stocks pure that they should be well rogued. Thin sowing and sticking greatly facilitate this, and there can be no doubt but that in this case it is thoroughly well done. That Peas do not intercross, grown side by side, is a blessing. Did they do so, as many other things will, to keep them pure would be a task indeed. Now I give the diverse varieties still standing, when I saw them, just as they came, and they serve to show that Maidstone and all that portion of the beautiful county of Kent around it can get a fine selection of Peas, as, indeed, the gardeners and cottagers of the county will have them. Between Maidstone and Swanley, the county is indeed fortunate in its seed growers and seedsmen.

The first batch of Peas included that first-rate long season and most useful variety, Walker's Perpetual, one in great request. This is 3 feet in height, carries a great crop, and the peas, even when the pods seem old, are still tender and sugary. Eckford Critic is less widely known. This grows to a height of 4 feet, and closely resembles Ne Plus Ultra, the pods long and full. The true Ne Plus Ultra is also largely grown; but that needs no description. The Duchess has become almost as well known as the Duke of Albany, which it closely resembles, but its pods are rather straighter and are well filled. Epicure reaches 5 feet in height; the pods are long and slightly curved. It is a great cropper and of much excellence; most certainly one of the finest of Peas. Sutton's Dwarf Defiance is 20 inches in length, and a very fine bodied dwarf variety, cropping heavily. It is a keen competitor in this class with Carter's Daisy, which is here also in quantity, and cropping well too.

Another capital Pea from Reading is Sutton's Windsor Castle, 3 feet in height, a great cropper, and has fine pods. A good Pea of Laxton's raising is Alfred the Great, which is a very fine form of Ne Plus Ultra, having rather longer pods than the type carries. It is 5 feet in height, and has a heavy crop. Fairbeard also some years ago gave us the famous Champion of England, as represented by Marvel, 4 feet high, a capital cropper, and of excellent quality. Of course Autocrat—not badly named, for it is of Peas almost the autocrat of the dinner-table—is here in a big breadth. The entire plant is, in spite of the long drought experienced, literally green as grass. It is, indeed, a splendid variety, cropping heavily. Another good Pea, but one that seems not to have been fully appreciated, is Sharpe's Triumph, 3 feet high, a splendid cropper, and, apart from its garden merits, is one of the finest market field Peas ever sent out. That fine new Pea, Boston Unrivalled, has pods of great length and profusely borne, is here in quantity also. A grand podding Pea is this, and, with Alderman, can hardly be excelled. A good stock of Veitch's Perfection is also grown.

Altogether, including such first early varieties as Bunyard's Early Dwarf, Chelsea Gem, Gradus, and William the First, it will be seen that an abundant selection of Peas is offered in Maidstone. Whence improvements are to come it is hard to tell. Pods and crops are now large enough for anything.

There is here a fine stock of Bunyard's Exhibition Longpod Beans, which seems to be a capital development of the Johnson's Wonderful type, the pods being not only very long, but tightly filled, seven and eight beans constantly occur in the pods. The early erect Longpod, a good stock of Taylor's Broad Windsor, and the large Mammoth Windsor are also in great abundance.—A. D.

Notes & Gleanings

EVENTS OF THE WEEK.—Horticulturists will not be quite so busy during the next seven days, though there are several provincial fixtures to be attended. Amongst these may be noted Alderley Edge on Friday, Weston-super-Mare on Tuesday, and Cardiff and Bishop's Stortford on the Wednesday, all of these being usually good shows.

—— WEATHER IN LONDON.—The heat in London since our last issue went to press has been exceptionally intense—indeed, Thursday last was one of the hottest days that have been experienced this summer. Friday was only a very little cooler, but on each day since then it has been pleasanter, owing to the breezes that have prevailed.

—— CLIMATOLOGICAL OBSERVATIONS AT DRIFFIELD, JULY, 1897.—Mean temperature at 9 A.M. (corrected), 63·17°; wet bulb, 57·69°; mean maximum, 69·58°; mean minimum, 49·04°. Highest, 79·6° on 30th; lowest, 38·0° on 18th. Mean of maxima and minima, 59·31°. Mean radiation temperature on grass, 43·91°; lowest, 30·2° on the 18th. Rainfall, 0·475 inch; number of rainy days, nine; greatest amount on one day, 0·1 inch on 5th and 28th.—W. E. LOVEL, *York Road, Driffield.*

—— COMMON PEARS.—Although the Pear crop this season is generally a light one, yet I have seen on very stiff soil, literally a strong clay, at Hook and Chessington, in Surrey, some wonderful crops of early and common varieties. Thus at Hook there are huge trees of the Windsor Pear, one said to be 130 years old, and in perfect health, carrying wonderful crops. The largest tree has probably on it 20 bushels. Further on, at Chessington, Green Chisel and Autumn Bergamotte, as well as other varieties not easily recognised, but of the same early and common order, and fine healthy trees, too, are heavily fruited. Certainly these trees, fruiting so constantly, show that they have very robust constitutions, and that they like the strong clay soil thoroughly. Large trees of Williams' Bon Chrêtien, have not a fruit.—D.

—— HOOK FLOWER SHOW.—At this local exhibition, held last week, Mr. E. Burrell, gardener to H.R.H. the Duchess of Albany, Claremont, staged numerous vases of hardy flowers in great variety, and some capital black and white Grapes, Peaches, Nectarines, and Gooseberries. Mr. Weddell, gardener to F. Clayton, Esq., sent a pleasing group of plants; Messrs. Barr & Sons, Long Ditton, had a capital collection of hardy flowers in bunches; Mr. Will Tayler, Hampton, sent beautiful H.P. and garden Roses, and Mr. Muxworthy charming Begonias, all exhibits being very highly commended. Of table decorations a charming exhibit was that of Miss Clode, which consisted of yellow Coreopsis flowers, sprays of Eryngium planum and Gypsophila, taking the first prize.

—— AN INTERESTING COMPETITION.—Two years ago Messrs. Cannell & Sons of Swanley placed at the disposal of the Richmond Allotment Holders' Association a handsome sash and £6 in three prizes, for competition between the allotment holders of Surrey and Middlesex. There was no competition that year, and last year only Hook (Surrey) entered the lists against Richmond, and came off second best. This year the Richmond Association handed over the place of competition to Hook, and as a result there were at this village Show on the 28th ult. five associations competing. These were Surbiton (the District Council Allotments), placed first with 61 points, County Council scale; the exhibits consisting of nine kinds of vegetables only. Richmond (the Corporation Allotments) came second with 56 points. Petersham (village allotments) was third with 55½ points; and Tolworth and Hook came with 53 and 45 points respectively. The latter Association members having their ordinary classes, put all their best produce into these, or they might have done much better. Next year, if the competition is continued, it will be at Surbiton, where only the challenge class can be competed in. The class aroused great interest, and numerous members of the Associations of Richmond, Petersham, and Surbiton came in the evening to learn the result. There is great probability that several other associations will enter next year. The classes were this year judged by Mr. Dean, Surrey C.C. Horticultural Instructor, and Mr. E. Burrell of Claremont Gardens.

—— THE ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Society will be held on Tuesday, August 10th, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 P.M. A lecture on "Cross Fertilisation of Florists' Flowers" will be given at three o'clock by Mr. James Douglas, F.R.H.S.

—— RAINFALL AT HAYWARDS HEATH.—The total rainfall at Haywards Heath, Sussex, for the past month was 0·50 inch, being 2·16 inches below the average. The heaviest fall was 0·18 inch on the 21st—rain fell on seven days. The maximum temperature was 86° on the 17th, minimum 43° on the 8th. Mean maximum 78·22°, mean minimum 53·07°, mean temperature 65·64°, which is 3·87° above the average. With the exception of 1885, this has been the driest July in our Mid-Sussex record of seventeen years, and rain is very much wanted. —R. I.

—— "FAMILIAR GARDEN FLOWERS."—Uniform with their popular edition of "Familiar Wild Flowers" Messrs. Cassell & Co. are now publishing the well-known "Familiar Garden Flowers" in twenty-one parts at 6d. each. The letterpress is from the pen of the late Mr. Shirley Hibberd, and is written in that gentleman's fluent and readable yet instructive style. There will be in the complete work 200 coloured plates by Mr. F. E. Hulme, F.L.S., and those that appear in part 1 comprise Wallflower, Michaelmas Daisy, Petunia, Monkshood and several others, each accompanied by explanatory notes. The paper is good, and the type clear, and at so low a price that the book should have a large sale. The parts are to be published weekly, and the second will be ready on the 13th inst.

—— LINCOLN AUTUMN SHOW.—Sixty classes are scheduled as being for competition in the exhibition to be held under the auspices of the Lincoln Chrysanthemum Society on Thursday and Friday, November 11th and 12th, in the Drill Hall of that city. There is an open section, as well as one for amateurs, and another for cottagers, with about eighteen miscellaneous classes in competition for which there is no residential restriction. Some capital prizes are offered for cut blooms and groups arranged for effect. Vegetables are neglected. For fruit we notice under the heading of Plants in the cottagers' section a class for five culinary Apples, and presume that plants in pots are required, for beneath are given suggestions as to size of pot and height of plant. The Secretary is Mr. W. Pask, from whom schedules and full particulars may be obtained.

—— ROYAL BOTANICAL SOCIETY OF MANCHESTER.—The schedule of a Chrysanthemum show that is to be held in the Town Hall, Manchester, on Tuesday and Wednesday, November 16th and 17th, has been sent to us by the Secretary. It is one of the smallest we have seen, containing twelve classes only, and is possibly unique in another respect—namely, that of offering its best prizes for incurved blooms. This class is for thirty-six incurved in not less than eighteen distinct varieties, nor more than two blooms of one sort, for which £7, £5, £3 and £2 are offered for the four best collections. Other prizes also are good, but full particulars may be had on application to the Secretary, Mr. P. Weathers, Royal Botanical Gardens, Manchester, who is hoping to get up an exhibition of good quality even if it is not large.

—— LITIGATION BETWEEN ORCHID GROWERS.—Judge Parry, sitting at the Manchester County Court, July 28th, heard the case of Ashworth *v.* Wells. It was an action brought by Mr. Elijah Ashworth of Harefield Hall, Winslow, against Mr. Matthew Wells of Sale to recover £50 damages in respect of a breach of a warranty as to the nature of an Orchid. It was purchased by the plaintiff in 1895. The plant figured in the catalogue as "Cattleya Acklandiæ alba, the only known plant." On behalf of the plaintiff, a number of well-known cultivators were called. They included Dr. Hodkinson and Mr. G. S. Ball, solicitor. Their evidence was to the effect that if the Orchid had been an alba, perfectly white and well shaped, it would have been worth from 70 to 150 guineas. It turned out, however, that the plant only produced a coloured flower of no particular value. It was the plaintiff's case that he believed the Orchid to be a genuine alba, and he thought he had got a bargain when he got it for 20 guineas. Mr. Tweedale, who appeared for the plaintiff, informed the Court that the action had been brought as a test case. It was submitted by Mr. Newman, who appeared for the defendant, that there had been no deception. His Honour reserved judgment, remarking that as two years had elapsed between the purchase and the parties coming into Court, they probably would not object if he took time to consider his decision. He added that the case would give him something to think over during his holidays.—("Gardeners' Chronicle.")

—— SPIRÆA ARIÆFOLIA.—How beautiful is this species with its creamy white plumes brought out in relief by the foliage of the shrubbery. After the first flush of summer in the flowering shrubs is over this graceful North American plant takes a high position. One regrets the evanescent character of its flowers.—E.

—— THE APPLE CROP.—Apples begin to show up more prominently as they swell in size, but we fear in most districts there will be but a poor yield. Taking the Apple-growing counties of Devon, Hereford, and Worcester we should say there will not be above half an average crop. This will make cider rather dearer from the pound's mouth in gathering time, but it will not affect that in barrels materially. Plenty, says the "Rural World," can be bought now at about 8d. per gallon at the farmer's door, and merchants are selling at about 9d. or 10d. per gallon. There is not an industry in England more neglected than the cider industry, and if properly managed there is no more profit to be made from any branch of farming.

—— THE AGRICULTURAL RATINGS ACT AND MARKET GARDENS — In the Queen's Bench Division in the High Court of Justice, on August 2nd, the appeal case of Smith *v.* Richmond and Piper was heard. The Attorney General, in support of the appeal, said the case raised the important point whether greenhouses or hothouses were buildings within the meaning of the Agricultural Ratings Act, 1896, which provided that the occupiers of agricultural land should be relieved of half of the rates payable in respect of such land. The respondent Piper was a market gardener and nurseryman, and claimed that his ground being a "market garden" was entitled to the relief granted by the Act, notwithstanding the fact that certain greenhouses and hothouses had been erected on the land for the purpose of growing Grapes, Cucumbers, Tomatoes, &c. The Assessment Committee held that the glass houses were buildings within the meaning of the Act, and therefore not entitled to relief. The justices, however, held that the land in question was a market garden, and entitled to relief. He (the learned counsel) submitted that the Act granted relief to agricultural land only, and not to buildings, even though they were used for agricultural purposes, and that therefore the decision of the justices was wrong. Mr. Justice Collins, in giving judgment, regretted to say he differed from the views of his learned brother, but he had come to a clear conclusion on the subject. The question was whether the hereditament which was the subject matter of this discussion was or was not a market garden. In his opinion the glass houses on the property were necessarily part of the market garden, and the land was not the less used as a market garden because the glass houses were erected upon it. He was of opinion that the buildings in question were part of the market garden, and as such the hereditament was entitled to the exemption given by the Act to market gardens. Mr. Justice Ridley said it was with great hesitation that he differed from his learned brother, but he had not been able to construe the Act in the same way. It appeared to him that the whole scope of the Act was to relieve what was called and defined as agricultural land. The intention of the Legislature was that arable, meadow, or pasture ground, cottage gardens of certain dimensions, market gardens, nurseries, grounds, and so forth were to be included as agricultural land, and that the occupiers should pay half the rates. The object was to contrast land entitled to relief with the buildings which were not so entitled, and there was no suggestion in the Act that buildings were entitled to relief. The dividing line seemed to him to be between land and the buildings, and if they once found a building in existence on the land it must be treated as such. But he withdrew his judgment, and the appeal was dismissed. Leave to appeal again was granted.

THE INFLUENCE OF TEMPERATURE ON PLANTS.

THE variety and magnificence of flowers are such that observations on the phenomena they present is indeed a delightful labour, divested of all wearisomeness. It is most important to notice the difference in colour and odour of flowers in various latitudes. An inhabitant of the north visiting the south is invariably much struck by the increase in these respects. Warm climates favour the development of essential oils. In the north, for example, the Oleander has but a slightly perceptive scent, but in Italy it exhales a powerful perfume.

The seasons, too, exercise a marked influence upon the colours of both leaves and flowers, more especially the latter. At the close of winter white predominates among the tints of the corollæ, to be succeeded by deep and vivid dyes that fade again in autumn. The temperature of the earth, especially that of the layers penetrated by the roots of trees, wants especial attention. It would be most interesting to follow the daily fluctuation of several thermometers, whose bulbs should be equidistant, in a vertical line, the uppermost one immediately under the surface, the others from a foot to a yard below it. This has been practised for many years with most interesting results, not only for botany, but also for meteorology. It is remarkable that whilst many flowers are susceptible to solar influence, others, on the contrary, are insensible to it.

Although the amount of influence due to each element of growth cannot be definitely determined, it is evident that temperature is a most important factor. Its influence on the organisation of a plant is like that of vital force, and to be estimated in squares of degrees. Two spring days, for instance, when the glass registers 50°, are not equal to one of 70°, for the effect of the latter would be greater than that of the two former. A country where the winter is mild, notwithstanding its latitude being high, will produce flowers earlier than other countries in a lower latitude.

Compare the west coast of England, for example, with France or Lombardy; Snowdrops and Crocuses flourish in full vigour before they are ready to open in Parma. But as the temperature increases with marked differences of intensity an equilibrium is soon established, and the southern regions in their turn take and maintain the lead. The period between foliation and flowering would also be less in Italy and Spain than in this country. It is said that plants in Belgium wake from their winter sleep towards the end of January. The farther from the sea towards the interior the lower is the temperature. Islands have a milder climate than continents.

The Hazel tree buds in the neighbourhood of London the first week in January, but in Brussels, singular to say, not before the end of February—a wide interval. The Crocus vernus also appears here at the beginning of February, nearly three weeks earlier than in Brussels. The greater mildness of our winter gives London the precedence at the commencement of the season, but it soon diminishes. In March it is only twenty days, in the first half of April only four, but from the middle of that month to the end of June Brussels is a week in front of London.

Extending the comparison to a more northern locality (Stettin in Germany) the advantage at starting in favour of London is double that over Brussels, but in July and August Stettin and Brussels are a week in front of London. According to observations made at Kelso in Scotland the period of foliation there is two days in advance of Brussels; Christiania in Sweden is fifty-two days later. There is a Chestnut tree in the gardens of the Tuileries in Paris which flowers abnormally early. It is called the Vingt Mars. It blossoms long before the others in the same gardens. It is said that latitude corresponds approximately in flowers, but there are important exceptions. Thus, although the difference between Christiania and Hamburg is but three days, it increases between the south of Germany and Smyrna to a week; whilst between Naples and New Jersey, both in the same parallel, it is actually two months.

An elevation in this country of 1000 feet is equivalent to a delay of fourteen days in the development of vegetation. A variable is more favourable than a uniform temperature. At Berlin, where the cold is great in winter, the orangeries flourish better than with us, whilst at Astrachan, where the thermometer at times registers 40° below zero, the most delicious Grapes are reared. Thus it will be seen that forwardness is not a constant beneficial characteristic of vegetation. The revivication of plants commences with the cessation of frost with us, and the period of foliation is compressed between the first great movement of vegetation and the covering of the plant with leaves, say about the end of April, from which time to the middle of July is the flowering period, whilst that of fructification is from that date onwards till the falling of the leaf.

The latter process depends mainly on temperature, the leaves generally falling with the first frost. The ripening of grain we all know is entirely dependent upon temperature. In Siberia, for instance, where it is above zero only for four months in the year, only Rye can be grown. This is only brought about by the action of the long day, which compensates in a measure for the weakness of solar action. Flowers present many interesting problems. In what degree do they depend on solar light and on the amount of moisture in the atmosphere? Why do some open in the day, or at certain hours, and others at night, some only when receiving the sun's rays, which, by-the-by, causes others to close? Do leaves close when their flowers open, and *vice versâ*?

Is there any relation between the colour of flowers and the time when they bloom? These are questions suggested in connection with the periodic phenomena of plants. The sun, as we say, exercises a positive and a negative influence, opening some flowers and closing others. Flowering plants, it has been demonstrated, grow better on a level surface than on slopes. The best slopes are the south and the south-eastern. The number of flowers produced in sunny spots is equal to three times that in shady situations. There is a difference in the colours of flowers according to the time of year. Thus white predominates in spring, and yellow in autumn. White flowers are most numerous throughout the year, yellow next, orange, red, green, blue, violet and indigo following in proportion as enumerated.

The proportion of flowers which open and shut is greatest in the yellow, smaller in the white, diminishing in the red, and least in the blue. White flowers increase rapidly from January till the vernal equinox, less rapidly from March to the middle of May, after which date they decrease. The greatest increase of yellow flowers is from April to June. Red flowers are more numerous in February than in April; they increase thence till September, and diminish in October and November, when red is the only colour remaining visible, save of late years in the greatly developed Chrysanthemum. In these phenomena there is a manifest dependance on the rise and fall of the temperature.—WM. NORMAN BROWN.

MINLEY MANOR.

THE county of Hampshire abounds in broad valleys, high hills, winding streams, waving woods and broad plains; and where its vegetation is practically limited to coarse grass and golden Furze it is interesting and even picturesque. Confining ourselves, however, to horticulture, we find that there are many beautiful estates maintained in splendid style, and amongst these is Minley Manor, near Farnborough, the home of one of our banker princes, Lawrence Currie, Esq. Here, in a lovely home, rest can be found from London's cares, and at the same time pure air can be had for the benefit of the organs that become sullied by the smoke of towns.

Much had been heard of the beauties of Minley—of the mansion, the grounds, the woods, and the plains, but it was only recently that, through the kind interposition of Mr. Jas. H. Veitch, the long desired visit was made an established fact. Less than two weeks ago was this journey made, and despite the drought that had then prevailed for a considerable time, an estate was seen which amply repaid the long train ride. To the writer it was a day of repose, despite the fact that many miles were traversed by rail and road and greensward. It was not a time of absolute quiet, for ever and anon would be heard, with at first startling distinctness, the boom of the guns of regulars and volunteers in the canvas town of Aldershot. These, however, lent the charm of variety for which we are all athirst. "Anything for a change," we are prone to say, and then when we have secured it, we do not perhaps know how to appreciate it properly.

Having taken careful stock of the instructions given by Mr. George Profit, the steward of the Minley estate, no trouble was experienced on detraining at Farnborough in finding our host and guide, for both these offices were undertaken by Mr. Profit himself. Anon we were bowling along comfortably towards our destination, uninterrupted by the several soldiers who were zealously searching for their enemies in the sham fight that was then being waged in the surrounding country. They gave one the impression that the heat was troubling them more than those enemies who were striving for the victory in this bloodless warfare. Leaving them as well as the village of Cove far behind, we sped by good country roads towards our destination, and the farther we progressed the more impressed we were by the natural beauty of the country through which we were travelling.

Turning down a side road, abutting upon which are the grounds of Sir Phillip Currie's Hampshire home, we quickly reached one of the several entrances of Minley Manor. A handsome lodge stands at the gate, while on each side are trees with seas of Heather to soothe the eye on every hand. From our guide we learn that the lake is the place to which he is driving, and following his directions we soon catch glimpses of the water between the trees, while far beyond in the Long Valley of Aldershot the tents of the soldiers are dotted thickly about. It is a lovely view of an entirely pastoral scene, and one that everyone would be forced to admire. Every now and again as we ascend and descend with the gravel road the view of the lake has been made more extensive by the removal of a number of trees, and at last we enter upon a grass drive that leads down to the water's edge. There are miles of grass as well as gravel drives on the estate, and admirably are they all maintained.

Alighting from the trap we make the preparations for a tour by water in a punt, and while this is being got ready we have a moment's peep in the boathouse, a substantial looking structure that is admirably adapted to the purpose for which it was erected. It is built upon good foundations and is not likely to come to decay for very many years. Of the lake itself much might be said, but a little will have to suffice. Its surface is broken by many islands of different sizes, upon the largest of which stands a thatched rustic summer house, and to this the boat was directed by strong and skilful hands, the landing stage which was cleverly hidden from the boathouse soon coming into view.

Walking round this island we at last come to realise what an immense stretch of water lies all around, and learn that it covers an area of about 40 acres. Commenced by the late B. W. Currie, Esq., four years ago, all the work has been done by Mr. Profit, and considering the brief space of time since a start was made, the result is nothing short of remarkable, for saving on the banks there are no visible signs of newness. The summer house, the inside of which is painted blue and white, looks clean and fresh; while the outside, all made up to pattern from timber cut on the estate, has quite an air of age with its thick thatch of straw and Heather and its surroundings. It is built in four bays, so that shelter can always be found from wind, and many beautiful plants, shrubs, and trees have been planted around. The selection of these has been made skilfully, and their condition proclaims how well they are thriving.

Re-embarking, we pass along the shore towards the other islands, to Sir Phillip's Creek at the head of the water, and to the overflow on the opposite side, returning beyond the large island to a handsome bridge of stone and red brick, which spans the water at its narrowest part. Immediately we have passed this we enter upon the stretch of water leading directly to the main entrance for the supply to the lake. Here there is a long avenue of recently planted Water Lilies, comprising all the best varieties at present in cultivation. Unfortunately the ducks have taken a fancy to the flowers, and make short work of them by pecking them in pieces. The plants as yet are only small, but they will, when thoroughly established, present a glorious sight with their beautiful blossoms of rose, yellow, and white. As we progress over the water we get occasional glimpses of the Manor between the trees, but always at too great a distance to see precisely what it is like. Instead of utilising the punt to return we pass by grass walks back to the boathouse, and see as we go how enormous has been the work of making this grand piece of water, which is in places about 10 feet deep. It is a monument to Mr. Currie's memory, and a great credit to Mr. Profit for his share of the work. Of course, when the banks are all finished it will be much more beautiful than it now is.

We now move rapidly away from the water on a broad smooth gravel drive, which is of a peculiarly good colour, and learn that every bit of gravel that is required is dug from pits on the estate. On each side are broad stretches of pure sand, in which even the Heather does not grow as it should do. We see in the distance hills clothed with trees, and advancing to the foot find them covered with magnificent Bracken, and notice that the character of the soil has changed completely, and is now of a loamy nature. Here, where alterations have been made and Heather planted, it grows luxuriantly on the slopes, and looks entirely different from the stunted growth on the sandy waste below. The trees vary in character very considerably; but Firs and Pines largely preponderate, and specimens of both may be seen of good size and beauty. Splendid Elms are noticed here and there, while Beeches and Oaks occur at frequent intervals. A feature that cannot fail to attract the attention of the visitor is the clever manner in which, when alterations have been carried out, every point of natural beauty has been seized upon, accentuated, and as far as possible improved.

Through a forest of Pines we emerge into a main road that divides the estate, and which has been improved by the late Mr. Currie, for from it turns the main entrance to the manor. But leaving this again for a short time we make straight for a broad table-like plateau known as Hartford Bridge Flats, whence views of very great beauty may be had in all directions. Almost across the centre of this is the main road from London to Southampton, and along it towards the latter town we continue for nearly a mile until a cross road is reached leading again to the estate, into which we drive down one of the most charming lanes one could possibly conceive. Flanked by high hedges in which Roses and Honeysuckle abound, and overhung by trees beneath which one is compelled frequently to bend the head, before and behind beautiful vistas and occasional peeps through the sides, it is a spot of singular loveliness which everyone must admire.

From this lane we turn into a drive that leads circuitously towards the mansion by a broad gravel path, on each side of which are grass banks planted with many magnificent Conifers. The trees are almost perfect in form, and rarely does one see specimens of which the colour is so rich and intense. Douglas Firs abound that are of exceptional beauty and occasionally of immense size, as well as Wellingtonia gigantea, several kinds of Cupressus, and many others. Some of these were large trees when they were planted, but notwithstanding this they look as though they had not been touched for a long term of years. As Mr. Profit has only been at Minley about thirteen years, whence he went from Coombe, and as these trees have all been manipulated by him since then, it is surprising how well they have grown. Smaller Conifers, with many flowering trees and shrubs, are observed at frequent intervals, but these cannot be enumerated here.

Up hill and down hill, through copse and over ravine, beneath high banks we proceed until the garden walls are seen in the distance.

Passing these for the time being, and also the front entrance of the mansion, we make our way to Minley Warren, the home of our guide, who throughout the long and beautiful drive, told of his experiences and his work at Minley, Coombe, and other noted gardens. Charming as has been our journey we are glad to leave the glare of the sun for the pleasant coolness of the house, where we sit at a window and see the flowers in the borders, the soft lawn, the cornfields, and the hills beyond. An interval now is taken up in partaking of Mrs. Profit's generous hospitality, which is followed by a brief rest ere we again emerge to seek "fresh fields and pastures new," and these, rest assured, are very easily found, and that without walking very far.

From one house of rest we pass to another and a more sacred, for it is God's house, in the ground round which lie the remains of Mr. Currie, who found relaxation in beautifying and improving the home that is now occupied by his son Mr. L. Currie. A shaded and secluded walk leads from the church to the mansion. On every hand here are to be seen hundreds of Rhododendrons, forming a groundwork for vegetation of a much larger growth. Near what was erstwhile the principal entrance stand two immense Hollies and another handsome lodge. Advancing still we quickly find ourselves on the terrace from which the landscape effects are varied and charming. This runs almost the entire length of the manor, which is a fine structure built in the style of a French château. An end view of the house is shown in the reproduction (fig. 18), which has as a foreground the Dutch garden that takes the place of the formal flower garden. The plants utilised in this garden, and which is, of course, the same year after year, were Golden and Silver Box, Golden and Common Yews, Euonymus radicans variegata, Cupressus Allumi and Lawsoniana lutea, with Juniperus tamariscifolia. It was laid out many years ago by Messrs. Jas. Veitch and Sons, and is pleasing because of its rarity.

The gateway seen leads to the front entrance, near which are some symmetrical Bay trees in enormous tubs, and that are relegated to the orangery in the winter months. However, we went in an opposite direction, through the few enclosed Rose and Erica gardens on to the plains, which are laid out in a manner that is nothing short of remarkable. There are immense beds of various sizes, each occupied with a certain kind of plant, from which rise trees whose leafage will form a contrast. One bed is devoted to Spiræa Anthony Waterer, another to S. confusa, a third to Olearia Haasti, a fourth to Berberis stenophylla; such trees as Prunus Pissardi, Snowy Mespilus, and others, being used with splendid effect. These are only a few of the many, in fact the superb collection is too large for specific mention. Besides these are long borders of hardy plants of various kinds, and from which cartloads of flowers might easily be cut. At the extremity is an ornate water tower for the supply of the beds, borders, and the gardens, the mansion having a tower of its own.

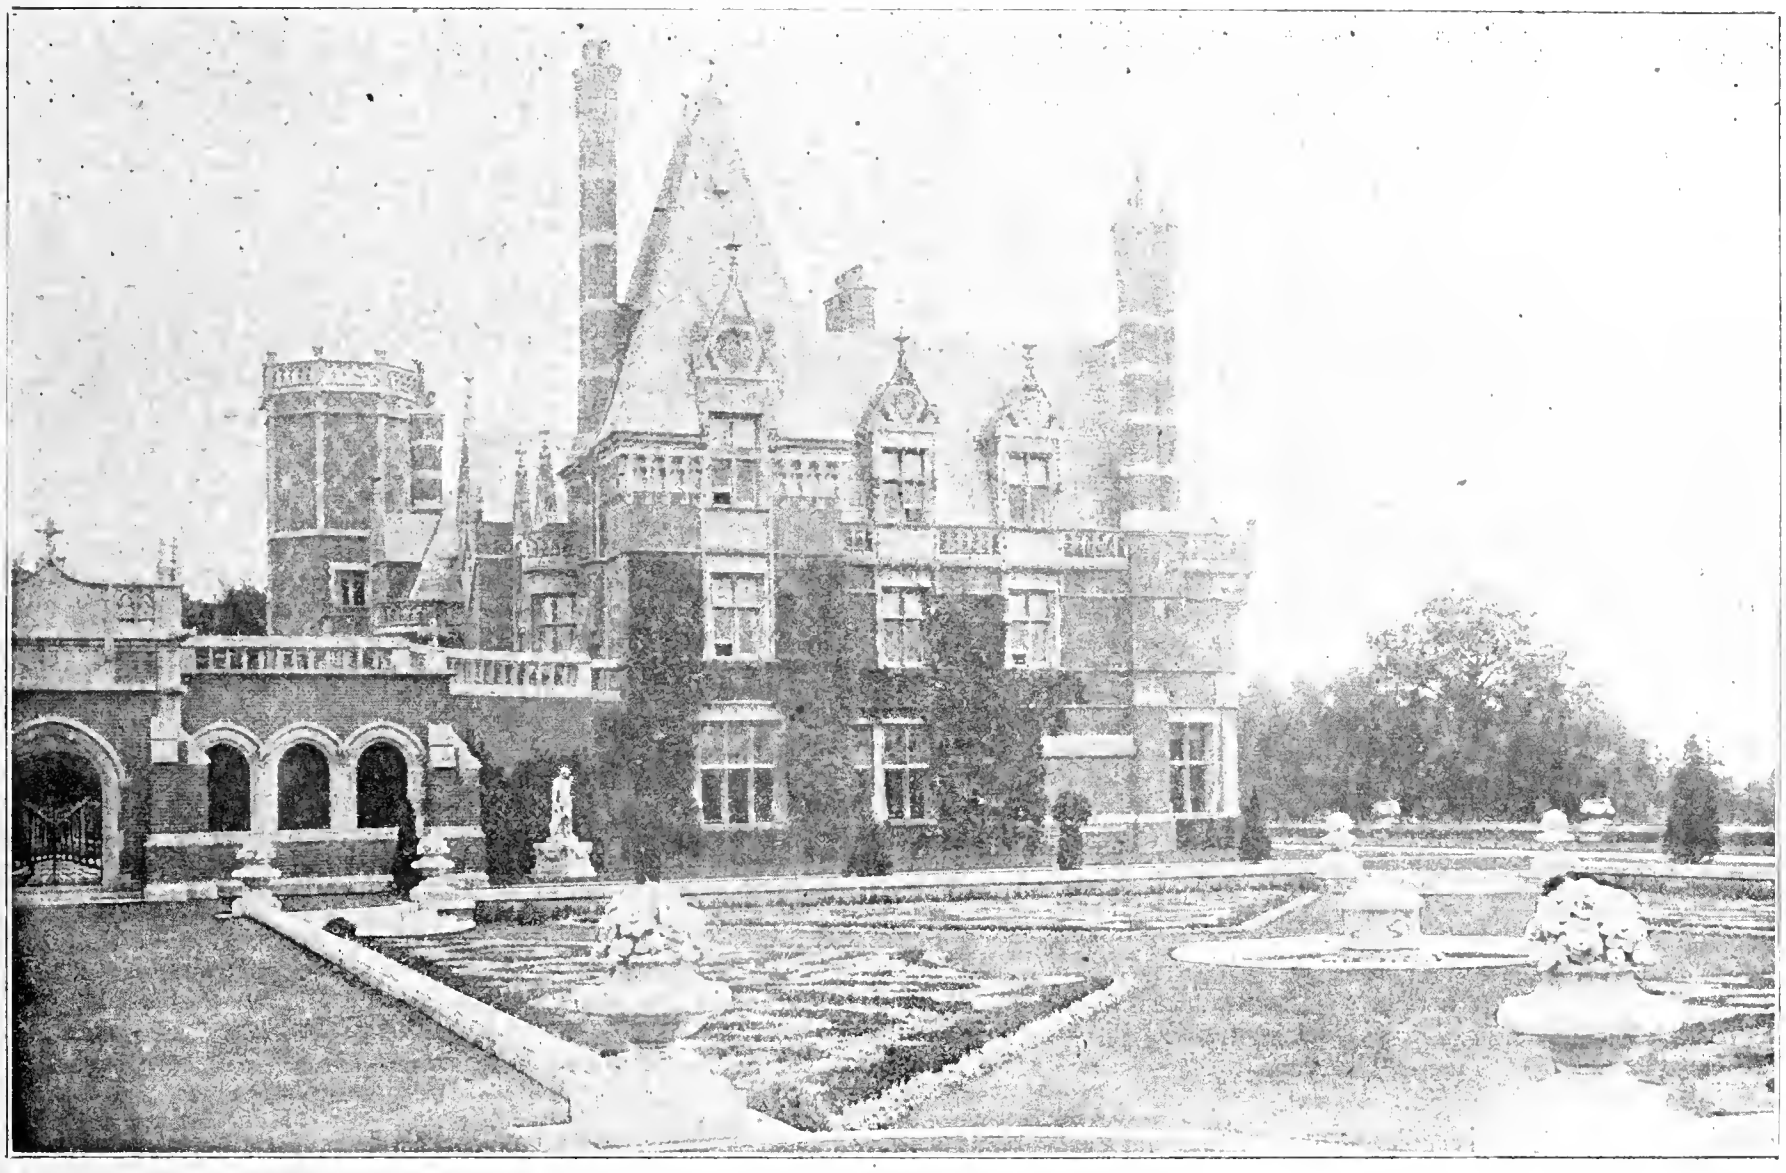

FIG. 18.—MINLEY MANOR.

The vegetable and fruit gardens are surrounded with capital walls, upon which are growing all kinds of fruits. In here, again, are many flowers, but of course the greater portion is occupied by fruit and vegetables. The former comprise many handsome pyramid Apples and Pears, and the crops are far from being bad ones. All kinds of seasonable vegetables are growing in their particular quarters, as are the several bush fruits. This department with the houses is in the charge of Mr. G. Tubbs, who was unfortunately out when this visit was made. However, his foreman kindly gave us a look through the plant and fruit houses, which contain Figs, Peaches, Nectarines, and Grapes, with the usual selection of plants. Outside rows of Chrysanthemums looked well, and should produce good blooms later in the year.

Back once more with Mr. Profit, with just time to get a cup of tea, and we are again in the trap. This time it is to the station, and by a different route, which is almost as pleasant as that traversed in the morning. Even from here the lake comes frequently into view, but we must say no more of Minley, though its beauties entitle it to extended reference. There is much left unsaid, but this must afford material for the next fortunate visitor.—H. J. WRIGHT

Chrysanthemums in New South Wales.

Mr. S. B. Levick has again prepared his annual audit of the best Chrysanthemums exhibited at the Sydney shows during the past season (April and May). The following is the result as set forth in the "Australian Agriculturist:"—Madame Carnot was shown twelve times; Good Gracious, eleven; Golden Gate, ten; Madame Calvat and The Queen, nine; Robt. Williams and Mrs. Jas. Murphy, seven; Louise, Eda Prass, and Vice-President Audiguier, six; Nyanza, T. Wickham Jones, Mdlle. Marie Recoura, L'Isère, Mrs. C. Harman Payne, Chas. Davis, Col. W. B. Smith, and Mrs. J. H. Horton, five; Buff Globe, Mrs. Hickman, Molesworth, Wallaroo, Miss M. Blenkiron, Mrs. E. D. Adams, Golden Wedding, and Viviand Morel, four; Eva Knowles, E. Forgeot, The Wonderful, Austral Queen, Oceana, Silver King, Wilfred Marshall, Mrs. Libbie Allen, Pallanza, and Philadelphia, three times each. There were eighteen varieties shown twice, and forty varieties shown once.

Certificated Australian Chrysanthemums.

Pride of Madford, Oceana, Australie, and perhaps a few more have been sufficiently long in cultivation here for us to form some idea of the value of Australian seedlings. That there will be others equally good in the course of time seems to be certain, for although during the past season new Australian seedlings were not exhibited in large numbers at the meetings of the Floral Committee of the Horticultural Society of New South Wales, several novelties were awarded first-class certificates, showing that the colonial raisers are still engaged upon the work.

Mr. G. Kerslake is credited with raising the following, besides others in previous years, which have had certificates awarded to them:—F. McQuade, Japanese, long petals, slightly incurving at the tips; colour bright terra cotta, reverse amber. Mr. J. H. Horton, Japanese reflexed; colour bronzy yellow, centre paler. Miss Mary Underhay, Japanese, broad incurved petals; colour primrose, but deeper than Kate Mursell.

Of varieties referred to in a former communication, a report in a colonial paper says—"J. R. Upton deserves special mention. This variety has everywhere been shown in splendid form, and is undoubtedly the finest yellow we have. Another magnificent variety is the white G. H. Kerslake, not yet distributed. The six blooms of this variety shown by G. Kerslake were magnificent. Wallaroo has also proved itself a very fine variety, and, as it is being distributed this season, it will probably be seen in several prize trays next year."—C. H. P.

ROYAL HORTICULTURAL SOCIETY.

Scientific Committee, July 27th.—Present: Dr. M. T. Masters (in the chair); Mr. Bennett-Poë, Prof. Church, Rev. W. Wilks, Mr. Veitch, Dr. Bonavia, Rev. G. Henslow, Hon. Sec.

Hybrid Orchid.—Mr. Veitch exhibited a new hybrid, Epilælia ×, between Epidendron radicans and Lælia purpurata. The former grows to from 7 to 8 feet in height, but the hybrid is only about 18 inches. Its leaves more resemble those of Lælia, nor does it root so freely as the Epidendron. The flowers are larger than those of the latter parent, and scarlet, but with a much broader and blotched lip, approximating that of the Lælia, though the deep mauve colour of this species is entirely wanting. Mr. Veitch observed that it is remarkable that the pollen of Epidendron radicans is potential in crossing Lælia, Cattleya, and Sophronitis, but not with itself. Dr. Masters remarked that this hybrid thus corroborated Reichenbach's statement that the two parents were allied.

Apples Diseased.—Dr. Bonavia inquired as to the nature of a disease which so commonly attacks Apples. Dr. Masters pronounced it to be most probably Fusicladium dendriticum, which attacks Apples and Pears, causing them to crack. Mr. Veitch observed that it generally occurs when the tree is in a poor condition, and recommended a renewal of soil in the autumn to strengthen the growth.

Wheat-eared Carnations.—Some examples of this well-known peculiarity were received from Mr. Colvile Browne of Hextable, Kent. Mr. Veitch observed that whenever Carnations were grown in large quantities for market, some plants generally appear among them with this malformation. Dr. Masters added that it was said that the immediate cause was the attack by mites at the apex.

Twin Apple Leaf.—Mr. Browne also sent a specimen in which two leaves were apparently united half-way up, and back to back. An examination of the distribution of the fibro-vascular cords showed that there was only one petiole, a section of which was crescent-shaped, with three or four cords on each half. These coalesced higher up into two distinct bands, from which the cords supplied to each of the twin blades arose. It was analogous to a foliaceous stamen of Jatropha, described by Dr. Masters (*Teratology*, page 255).

Lantana Attacked by Insects.—Specimens were received from Chiswick covered with a white mealy bug known as Orthezia insignis, *Douglas*, and called the "Kew bug."

Seeds Germinating within a Melon.—A specimen was received in which this peculiarity had occurred. It is not infrequent in Cucumbers, Oranges, and the Papaw. It was observed that the cotyledons were green, though in the absence of light within the fruit. Such occurs also in Pistacio Nuts, Mistletoe, pods of Cassia fistula, &c. Professor Church remarked that it probably arose from some modification of the rays of light which were capable of "greening," although their energy was altered in character. It is observable that plants turn green under all the coloured rays of the spectrum, though Ferns will be green in total darkness if the temperature be adequate.

Pelorian Calceolaria.—Mr. Henslow showed two flowers of the ordinary yellow bedding-out plant, which had assumed the sleeve-like shape instead of the usual slipper.

Cypripedium two-lipped.—Dr. Masters showed a specimen with this malformation, the flower being apparently also changed as to the number of its parts. It appeared to be really synanthic, like the Cattleya shown at the last meeting.

Rosa rubrifolia.—He also showed a spray of this red-leaved species, received from Mr. G. Paul, having the gall, "Robin's pincushion," likewise intensified in colour.

Hybrid Aristolochia.—Dr. Masters showed a blossom of the first hybrid ever raised in this genus, between A. gigas (form) and A. elegans from Bolivia. It will be more fully described elsewhere.

Cream-coloured Vallota.—He also exhibited blossoms of this variety. A white one is known to have existed, but is apparently lost to cultivation. It was suggested that crossings should be made with the present one, so that possibly the white variety may re-appear.

Chemical Analyses of Orchids. — Prof. Church, having carefully considered Mr. Smee's second paper on the chemical processes which are supposed to take place in Orchids, observed that it was somewhat difficult to follow the author's observations, as there was a want of systematic cohesion throughout the paper, some parts appearing to be rather irrelevant and others open to question. Thus chemists are not agreed upon the composition of chlorophyll, and if they were there would be in consequence no special light thrown on the cultivation of Orchids. In his observations upon the presence of nitrogen in sewage grass Mr. Smee had altogether omitted any mention of nitrates, and no conclusions can be drawn from the absolute quantities given, as they bear no relation to the actual quantities employed, but not stated in the experiments. The diagram supplied by Mr. Smee Prof. Church thought interesting, as approximately representing the gradual loss of earthy salts as one of the causes of decline and death. With reference to his observations on phosphates in connection with the flowering process, it is well known that phosphates generally increase the inflorescence, while nitrogen enhances the foliage and deepens the green colour of chlorophyll; but Mr. Smee's remarks upon the decomposition of phosphates are extremely doubtful. It has been found in all experiments that ammonias in which phosphorus has replaced nitrogen have always proved fatal to plants. Mr. Smee's experiments on scents, as being formed in the flower itself, are well founded. Lastly, the suggestion that thorough analyses should be made of all parts of Orchids was advisable, if practicable; but such would require very accurate work on definite lines. Such only would give valuable results.

A "GOLDEN GARDEN."

Outside a comparatively small district in Buckinghamshire the Wing Horticultural Society is practically unknown, yet the special favour of an exceptionally advantageous situation for its annual Show bids fair to raise it to a high level amongst local organisations of a similar kind. When Leopold de Rothschild, Esq., with a generosity that distinguishes a great family, permitted the Wing Society to hold its exhibition in the grounds at Ascott, and, further, threw open his beautiful gardens to all visitors, the success was assured provided only that fair weather could be secured. This condition was amply fulfilled last week (July 29th), when crowds of visitors from Leighton Buzzard and the neighbourhood flocked into the Show, and spent a most enjoyable afternoon amidst the numerous attractions of a superb garden. The visitors were not, however, confined to residents in the district, for excursions were provided from Bedfordshire and Northampton, which brought many to whom the charms of Ascott had been hitherto unknown, and they departed both surprised and satisfied.

As a matter of fact little can be said about the exhibition itself. There were the same arrays of well-grown vegetables most country shows provide, there were also cut flowers and plants in moderate numbers, all, however, examples of good culture and care, with an additional tent devoted to groups of plants which were either from district or distant nurserymen (Messrs. J. Veitch & Sons, and Cutbush & Sons being amongst the latter). Respecting them nothing need be said in these notes, because the chief object is to refer to what was after all the greatest attraction to visitors—the garden. Perhaps it would scarcely be possible to select any time in the whole year when Ascott could be seen to better advantage then July or August; there is such a wealth of shrubs, trees, and plants that in favourable seasons have by that time made their best growth, and are seen at once in their freshest and richest attire. At intervals, from the early years of this garden, the writer of these notes has had the opportunity of observing the progress made, the gradual development as it were of the ideas which influenced the designers and planters. Each visit has in this way yielded greater satisfaction, until on the occasion under notice it seemed that the picture was completed. It

is difficult to see in what respect the general design could be improved, and though further years' growth may furnish larger specimens the majority of the shrubs and trees have reached a stage in which all their attractions are sufficiently developed to satisfy the most exacting admirer.

Ascott is undoubtedly unique as a garden, and though tastes differ as to styles, if one is adopted absolutely and carried out freely and well the results are often such as surprise or even please the advocates of other methods. A bold course was adopted in this garden when it was determined to make golden leaved shrubs and plants the great feature of the place, but that the fullest measure of success has been attained is evident to the most critical if the results be inspected on a brilliant summer's day. The hedges and beds of Golden Yews are now in perfection, and it is doubtful if such an extensive array of this richly coloured shrub could be seen elsewhere in the kingdom. Two points particularly strike a visitor when viewing them, the first being the remarkable uniformity in colour and habit, showing the care with which the plants were selected, and the second is their healthy condition, proving that the original preparation and subsequent treatment have been exactly what the plants required. It is not uncommon to see isolated specimens of Golden Yews on lawns, and occasionally the variety elegantissima assumes a very handsome form and rich colour, but the latter quality does not always last so well. The true aurea (Taxus baccata aurea) is one of the most useful golden shrubs, as it makes good progress and bears cutting well.

The best point at Ascott to see the plants is near the sundial, from which a good view is obtained of the celebrated Madeira Walk, having a fine hedge of Golden Yews on one side and a terrace wall on the other. Several other hedges run off from this, all even as a wall and all equally richly coloured, the effect being heightened by massive "pillars" of the ordinary dark green variety at the entrances to the Fountain Garden. The wall of the Madeira Walk is surmounted by a low hedge of Golden Hollies, similarly well coloured; but the face next to the walk is draped with grand masses of rich purple Clematis (Jackmanni), the plume-like heads of Ceanothus, the bright red flowers of Escallonias, with Roses in abundance. Scarcely an inch of the wall itself is visible, and though we know that much gardening skill and labour have been expended upon the planting and training here, yet so free and natural does it all appear that one might fancy it was not the production of art.

In other parts of the garden Golden Hollies, Arbor Vitæ, and Privet are used with good effect, but the standard plants of Golden Privet are, perhaps, the most notable, the stems 4 to 6 feet high, the heads freely developed, and the foliage richly coloured. They are introduced amongst dark-leaved shrubs, and, rising slightly above them, have a very telling appearance, which is almost equally shared by silver variegated standard Privets. Some charming combinations and contrasts have been skilfully managed at various points, and two dwell in the memory especially. In both of these the variegated Maple, Acer negundo variegata, is conspicuous, a luxuriant specimen in one case being partly covered at the corner of a dark background of trees and shrubs with festoons of Clematis Jackmanni, the purple flowers of which mingle charmingly with the silvery white foliage of the Maple. The other example is by the rockery steps leading to the upper garden, where some fine Copper Beech are contrasted with the same variegated Maple, a superb effect resulting.

The dells and banks and cool retreats of the water garden furnish a considerable attraction, and especially is this department appreciated on a hot summer's day, the Bulrushes, Reeds, and Water Lilies being all in vigorous growth now; but especially fine is Gunnera manicata, which seems to be thoroughly at home, huge specimens having a grand appearance near the margins of the pools. The rock garden also is rapidly becoming another of the Ascott features. Respecting the glass department the vigorous Carnations and the innumerable other attractions nothing can now be said, except that they form a portion of the magnificent garden, of which Leopold de Rothschild, Esq., has every reason to be proud, and every portion of which reflects the skill of his gardener, Mr. Jennings.—L. CASTLE.

KEW GARDENS.

OPENING OF A NEW HOUSE.

ON Sunday, July 25th, the new wing, which has recently been added to the Winter Garden at Kew, was opened to the public for the first time. The new part forms a noble addition to an already fine structure. It is 114 feet long and 63 feet wide (inside measurement), and differs from the old house by being much lighter, having everything planted out, and higher temperature. A path runs through the centre of the building, making a continuation of the path through the middle of the big house and octagons. This path from end to end measures 456 feet.

The house contains six beds, four in the middle and two round the sides and ends, all the beds being separated by paths. Each of the centre beds is 41 feet by 15 feet 8 inches, the side ones, with the ends, being each 148 feet by 7 feet. The occupants of the house are numerous and varied, about 500 species and varieties being planted. Plants of economic value, which require an intermediate temperature, come in for a large share of attention. Among the most noteworthy are Cinchona, in variety, Cyphomandra betacea, Tree Tomato, Diospyros Kaki (in fruit), small collection of Eucalypti, Eugenia Jambos, Rose Apple, various species of Ficus, Carica, and Kigelia. The purple Guava, Psidium Cattleyanum and the Mango are both to be seen in fruit.

Of flowering plants, some of the most noteworthy are Lagerstræmia indica, two large plants 8 feet high and as far through, smothered with large panicles of rose pink flowers; Lagerstræmia elegans, with flowers of a deeper colour than the former; Erythrina Humei, with several upright racemes of scarlet flowers; Luculia gratissima, Acokanthera spectabilis, Mackaya bella, the rare Blakea trinerva, a collection of the garden varieties of Malay Rhododendrons, Barnadesia rosea, Alberta magna, and a host of others.

Foliage plants are also in evidence. An avenue is formed along the sides of the middle path with Cocos plumosa, a fine plant of the "Blue Palm;" Erythea armata, a good specimen of Howea Belmoreana; also plants of Geonoma gracilis, Pseudophœnix Sargenti, Cocos Weddeliana, and others. Erythrina tomentosa makes a good effect with its large handsome foliage. A specimen of Leucadendron argenteum makes a fine contrast to the surrounding plants. Many other foliage plants, such as Dracæna Lindeni, Lomatia Bidwilli, Musas, and Aralias. The

FIG 19.—INDIGOFERA GERARDIANA.

ends of the two middle beds near the south door are made up with rockwork, which accommodate numerous Mexican and South African plants, such as Agaves, Aloes, Cereus, Opuntias, and Euphorbias. A selection of good climbers covers the roof and pillars, finishing a large collection of interesting plants.

INDIGOFERA GERARDIANA.

In a natural order of plants where the majority of the hardy shrubby section possess considerable merit as good garden plants, it is a risky thing to say that any particular one is the best. It can, however, be said of this that it ranks among the foremost. It is a temperate Himalayan plant, and is one of the hardiest of the genus. The pinnate leaves are made up of from seventeen to twenty-three oval leaflets, which are pale green above and silvery beneath. The flowers are rosy red, and produced forty to fifty together on slightly drooping racemes along almost the entire length of the current year's growth (fig. 19).

It is a good-natured plant, and lends itself for a variety of purposes. If planted against a wall, and spurred back each spring, longer branches are made than when grown in the open, with a correspondingly larger inflorescence. For a bed where a low-growing shrub is wanted this does beautifully. When treated in this way it will be found necessary to cut back the growths to the top of the soil each spring, as the growths being soft they are usually damaged by frost. In April they start strongly, and by the end of June are showing their earliest blossoms; it is not, however, until the end of July and all through August that the greatest wealth of bloom is obtained. When planted against a wall the flowers are at their best a fortnight earlier. Cuttings inserted in sandy soil during July and August, and kept close and on the dry side, root readily.—W. D.

HORTICULTURAL SHOWS.

CHESTER.—JULY 28TH AND 29TH.

THE second annual exhibition of the Chester Horticultural Society opened on the above dates under a threatening sky; but, fortunately, rain held off until night. In the evening the famous Roodee was visited by thousands of sightseers. Thursday opened with real flower show weather, and it is hoped the Committee of this enterprising society will secure a good gate. There was a marked falling off in the number of exhibitors from the show of last year, the tabling in many instances being bare. This is regretable, as the Society offers good prizes, and the tent accommodation at this exhibition was a great improvement on that of last year, being lofty and wide.

The chief features of this show were the splendid group set up by Mr. Cypher, the Carnations from the Duke of Westminster, and the specially fine exhibit of Messrs. Dicksons, Limited, Chester. Sweet Peas were also well to the front, being staged in large quantities. Vegetables were largely represented in the amateurs' and cottagers' classes, the quality of the same being of a high standard of excellence.

GROUPS AND PLANTS.

There were five competitors in the class for a group of plants arranged for effect, to occupy a space of not more than 300 square feet. Mr. J. Cypher, Cheltenham, was awarded the first prize, with a lovely arrangement of Orchids, graceful Crotons, Carnations, Aralias, Humea elegans, Liliums, Asparagus, and Bamboos. Mr. J. McIntyre, Woodside, Darlington, was a good second, whose group contained many beautifully grown plants of Crotons and Palms, but lacked the grace and elegance of the first group. Charles Wigg, Esq., Hoole Bank, Chester, was third; and Mr. John Robson, Altrincham, a fair fourth.

For group of plants arranged for effect in a space not exceeding 100 feet, open to county of Chester and North Wales, there were only two entries. Mr. R. J. Hudson, Bache Hall, Chester, was a good first with a pleasing arrangement, and Mrs. Townsend Ince, Christleton Hall, Chester, a fair second.

For the best twelve specimen plants Mr. J. Cypher, Cheltenham, was to the front with splendidly grown Erica Austiniana, Bougainvillea glabra, Ixora Williamsi, Statice profusa, Ixora salicifolia, Phœnocoma prolifera Barnesi, Kentia australis, Kentia Fosteriana, Latania borbonica, Kentia Belmoreana, Croton mortefontainensis, and Croton angustifolius. T. S. Timmis, Esq., Cleveley, Allerton, Liverpool, was a fair second. His best plants were Clerodendron Balfourianum, Ixora coccinea superba, Ixora Pilgrimi, and Kentia Belmoreana. Mr. Wm. Vause, Leamington, was third.

Mr. J. Cypher was to the front for a single specimen Palm with Kentia Fosteriana, Mr. J. McIntyre was second. The best greenhouse plant in bloom came from Mr. J. Cypher, Phœnocoma prolifera Barnesi being represented. J. Charlton Parr, Esq., second with a fine Disa grandiflora. Mr. W. Vause took first place with single specimen stove plant, showing Ixora Fraseri. Mr. J. Cypher second.

Dracænas were represented by fresh specimens, not large but well clothed to the pots. T. S. Timmis, Esq, was a good first; W. H. Watts, Esq., Elm Hall, Liverpool, second, and Mr. J. McIntyre third. Twelve Caladiums in variety were represented by splendid plants, T. S. Timmis, Esq, was a good first; Charles Wigg, Esq., second, and B. C. Roberts, Esq., third. T. S. Timmis, Esq., took the lead for four Crotons in variety; Mr. J. McIntyre second. Ferns were very fine. T. S. Timmis, Esq., was first for six exotic Ferns, staging Nephrolepis davallioides furcans in splendid form, Davallia fijiensis also very fine, Nephrolepis rufescens tripinnatifida (grand) with Microlepia hirta cristata, and two good pieces of Adiantum cuneatum. W. H Watts, Esq., was second, his best plants being a lovely Gleichenia Mendelli and a good plant of Microlepia hirta cristata. Mr. J. McIntyre was third.

The class for twenty-four plants suitable for table decoration was well filled, the numerous exhibitors staging on the whole highly creditable plants. Mr. J. Gray, gardener to Sir G. A. Meyrick, Bart., Bodorgan, Anglesea, was first with a beautiful collection. Mr. B. Cromwell was a good second, staging the whole number in Crotons; Mr. J. McIntyre third, and Mr. J. Bracegirdle fourth.

CUT FLOWERS.

Only one competitor staged for the best display of cut flowers in any design or combination of designs, at the discretion of the exhibitor. Rising from a formal design of Violas, Coronilla varia, yellow Calceolaria, and moss were centrepieces containing Sweet Peas and Carnations, the greenery being Asparagus deflexus, Gypsophila elegans, and Ferns, arranged by the Misses Hopkins, Mere Cottage, Knutsford, Cheshire.

Forty-eight Roses, distinct, were represented by four good exhibits. Messrs. Harkness & Sons, Bedale, were to the fore with fine blooms. Messrs. A. Dickson & Sons, Newtownwards, Co. Down, were a good seeond; and Messrs. D. & W. Croll third. Messrs. Perkins & Son, Coventry, were successful in the class for twenty-four distinct, showing a creditable stand. Mr. Peter Snelson, Hope Street, Mold, was placed third. Only two competitors staged in this class. Twelve Roses, distinct, were well staged by Mr. Hugh Dickson, Royal Nurseries, Belfast. Twenty-four Tea Roses were staged by two exhibitors only. Messrs. Alexander Dickson & Sons were first, and Messrs. D. & W. Croll, Dundee, a fair second.

For the best arrangement of cut flowers in vases or stands for table decoration, Messrs. Jones & Sons, Shrewsbury, won with a pleasing arrangement of Carnations, Francoa ramosa, Gypsophila elegans, and Asparagus. Mr. Wm. Vause was a good second, and Messrs. M. Hodgkins & Co. third.

For an arrangement of Carnations and Picotees in variety in a space 10 feet by 6, seven stands were staged, the whole making a very effective display. The first prize went to M. R. Smith, Esq., Hayes, Kent, for a very fine exhibit, the flowers being wonderfully fresh, also of good substance and size. Mr. Wm. Watson, Clontarf Nurseries, Co. Dublin, was second, and Messrs. Thompson & Co., third. Messrs Perkins and Sons, Coventry, were first with bridal and ball bouquets, and Messrs. Jones & Sons for buttonholes.

NURSERYMEN'S CLASSES.

For the best display of cut Dahlias in a space 10 feet by 4 feet, the first prize was carried off by Messrs. Jones & Sons, Shrewsbury, for a nice arrangement of Cactus, Pompon, and Show varieties. Very fine in the Cactus varieties were Miss Webster, Cinderella, Countess of Radnor, Mrs. F. Fell, Matchless, Mrs. A. Peart, Mrs. Gordon Shaw, Harmony, Lady Penzance, and Cannell's Gem. Of Show varieties Mrs. Gladstone, Mrs. Slack, Emperor Muriel, Pioneer, John Walker, John Rawlings, Duke of Fife (grand), Canary Bird (very fine), and Mrs. Stancombe were fine. The Pompons also were very bright and fresh. Mr. M. Campbell, High Blantyre, second, and Mr. J. Walker, Thame, Oxon, third.

Of collections of hardy flowers in variety, occupying a space of 15 feet by 4 feet, two highly meritorious exhibits being staged. Mr. W. F. Gunn, Olton, Birmingham, showed fine Phloxes Amazone, Sheriff Ivory, Harrison Weir, and The Queen, Gaillardia grandiflora, Lychnis chalcedonica, Achillea Ptarmica The Pearl, Scabiosa caucasica, Campanula carpatica alba, Agrostemma coronaria alba, Catananche alba, Centaurea Tourneforti, Montbretia crocosmæflora, and many others, and received the premier award. Messrs. Harkness & Sons were a good second with a more crowded arrangement, but the quality of the flowers was fine, specially so being Coreopsis grandiflora, Potentilla La Vesuve, P. Wm. Rollinson, Gaillardia grandiflora Jealousy, and Catananche cœrulea.

For the best display of cut Roses arranged with natural foliage, and occupying a space of 8 feet by 4 feet, three staged. Messrs. Perkins and Sons, Coventry, were well to the front with artistic arrangements in epergnes and baskets. Messrs. Harkness & Sons and W. F. Gunn were second and third in the order named.

FRUIT.

For a decorative display of ripe fruit on tables 10 feet by 4 feet 6 inches, the fruit not to exceed eighteen dishes, and of not less than seven kinds, the first prize was awarded to Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby. The best dishes were Bellegarde Peach, Pinapple Nectarine, Black Tartarian Cherries, Read's Scarlet Melon, Brown Turkey Figs, and Beauty of Bath Apple. Muscat Hamburgh Grape was represented by a good bunch, as also was Muscat of Alexandria, but the latter was a little under-ripe. The other dishes were a small Queen Pine, Elton Pine Strawberry, Lord Napier Nectarine, Large Early Apricot, Lady Sudeley Apple, Belle d'Orleans Cherry, Countess Melon, Noblesse Peach, and Black Hamburgh Grapes. The centre of the table was covered with a mirror, on which were arranged elegant vases of Masdevallias, Cattleyas, Odontoglossums, the greenery being Asparagus, Selaginella cœsia, and Myrsiphyllum asparagoides. The number of points gained was seventy out of possible 100. Mr. J. McIndoe, gardener to Sir J. W. Pease, Bart., M.P., was a splendid second, the points scored being sixty-seven. There were fine dishes of Muscat of Alexandria, Golden Champion, and Black Hamburgh Grapes, Stirling Castle Peach, Souvenir du Congrès Pears, Spencer Nectarine, Prince Englebert Plum, Gunton Park Strawberry, Duchess of Gloucester Apple, Negro Largo Figs, and Early Transparent Plum. Mr. Read, gardener to the Earl of Carnarvon, Bretby Park, Burton-on-Trent, was third, obtaining fifty-three points.

For a collection of ripe fruit, to include two bunches of white and two bunches of black Grapes, there were three exhibitors. Mr. Harris, gardener to Lady Henry Somerset, Eastnor, Ledbury, secured first honours with small Black Hamburgh and Muscat of Alexandria Grapes, fine Bellegarde and Stirling Castle Peaches, Pitmaston Orange and Stanwick Elruge Nectarines, excellent Brown Turkey Figs, Countess and an elongated seedling Melon, and splendid Bigarreau Napoleon Cherries. Lord Bagot, Rugeley, was second with well-coloured Black Hamburgh and fair Muscat of Alexandria Grapes, a huge Hero of Lockinge Melon, Violet Hâtive Peach, and Violet Hâtive Nectarine as the best dishes. Mr. J. Edmonds, Bestwood Gardens, took the third place.

For a collection of eight dishes of hardy fruit four exhibitors staged. Mr. Harris was placed first. Bigarreau Napoleon and fine Morello Cherries, Moor Park Apricot, Oxonian Strawberry, Superlative Raspberry, and large Red Currants were the best dishes. Viscount Combermere, Combermere Abbey, Whitchurch, was a good second. This collection contained fine Strawberries, Black and Red Currants, nice Cherries and Gooseberries. Capt. Fielden, Mollington Hall, Chester, was third. Mr. Harris again secured premier honours with a fine Smooth Cayenne Pine, Mr. Read taking second place.

For the best six bunches of Grapes, two bunches of each, in three distinct varieties, there were seven stands staged. Mr. W. Pritchard, Little Neston, was first, showing good Black Alicante, Muscat of Alexandria, and well-ripened Bowood Muscat. Mr. J. A. Goodacre was second with fine Muscat Hamburgh, Muscat of Alexandria (not nearly ripe), and fair Black Hamburgh. Sir G. A. Meyrick, Bart., Bodorgan, Anglesea, was third. For three bunches of Black Hamburgh R. T. Richardson, Esq., Capenhurst Hall, Chester, was first; Lord Bagot second, and Mr. Harris third. Only two staged in the class for three

bunches of Madresfield Court, Mr. Harris being first, and R. A. Naylor, Esq., third. Three bunches of any other kind, E. A. Young, Esq., was first, showing fine Gros Maroc; Mr. W. Pritchard second with Black Alicante; and Lord Bagot third. There were three exhibits for three bunches of Muscat of Alexandria Grapes, the prizewinners being E. Edmondson, Esq., Springfield Hall, Knowle; Lord Bagot, and E. S. Clark, Esq., in the order given.

For a single dish of Peaches Mr. Harris was first, showing Bellegarde; and Mr. J. H. Goodacre second. The last-named exhibitor was first with six Nectarines; Lord Bagot second, and Mr. J. McIndoe third. For the best Melon, any kind, the competition was very keen, Countess, exhibited by Mr. J. H. Goodacre, taking first place. Mr. Harris second with the same variety, and Mr. Read third. For Figs Mr. Potts was to the fore, followed by Mr. Harris and Mr. J. Edmonds. The class for a single dish of fifty Cherries was very fine. Mr. Harris was again successful, followed by Viscount Combermere and Lord Bagot.

Vegetables.

Considering the season these were of very fine quality. For a collection of twelve distinct kinds Mr. T. Wilkins, gardener to Lady T. Guest, Inwood House, Henstridge, was first with a splendid collection, admirably staged. There were Autumn Mammoth Cauliflowers, selected Ailsa Craig Onion, Sutton's Solid White Celery, Green Globe Artichokes, Early Gem Carrots, Duke of Albany Peas, Perfection Tomatoes, Best of All Runner Beans, Satisfaction Potatoes, Sutton's Globe Beet, Improved Telegraph Cucumber, and Prizetaker Leek. Mr. C. Foster, gardener to Morgan S. Williams, Esq., Aberpergwm, Glyn Neath, was second; and Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury, third.

In the class for the best collection of eight distinct kinds, open to Cheshire and North Wales, Mr. Prior, gardener to the Hon. Mrs. E. Kenyon, Maisfaen Hall, Whitchurch, took first place with fine Autumn Mammoth Canliflower, selected Ailsa Craig Onion, Sulham Prize Celery, Magnum Bonum Pea, Perfection Tomato, Progress Cucumber, Satisfaction Potato, and Early Gem Carrot. Mr. C. Worker, gardener to Capt. Fielden, was second, having good Cauliflowers, Peas, and Leeks; and Mr. J. Oldfield, Chirk, third.

For six Onions Mr. T. Wilkins was first, staging grand bulbs of Sutton's Selected Ailsa Craig. Mr. C. Foster was second, and Mr. John Coke third. For Leeks Mr. Pope took first with fine Prizetaker; Mr. T. Wilkins second, and Mr. Rodger Varley third. Carrots were well shown, Mr. T. Wilkins winning with very fine specimens of Sutton's New Red Intermediate; Mr. C. Foster and J. Oldfield, Esq., taking second and third in the order named. There was strong competition for six Beet. Mr. C. Foster was first, Mr. T. Wilkins second, and Mr. Pope third. Mr. Logan was first with Cucumbers, Viscount Combermere second, C. Peele, Esq., third.

Twelve kidney Potatoes made a good class. Mr. B. Ashton was first, Mr. C. Foster second, and Mr. Pope third. Mr. B. Ashton was awarded first for the best twelve round Potatoes, Mr. Wilkins second, and Mr. Pope third. Mr. Ashton was first also with coloured kidneys, Mr. Cheers second, and Mr. A. Ruddock third. The same exhibitor took first for coloured rounds, followed by Mr. W. Pope and Mr. C. Foster. The last named staged the best Cauliflowers, Mrs. Watkins second, and Mr. W. Pope third. Mr. Varley won with red Celery, followed by Mr. C. Foster and Mr. J. Birch. Mr. Pope won with white Celery, Mr. Varley second, Mr. T. Wilkins third.

Peas were very well shown, T. Brocklebank, Esq., Mr. H. Brownhill, and Viscount Combermere being the winners. Mr. Wilkins, Mr. W. Pope, and Captain Fielder winning with Best of All Runner Beans. Mr. Wilkins was to the front with French Beans, staging fine selected Canadian Wonder; Viscount Combermere second; and Mr. Prior third. For the special prizes offered by Messrs. Webb & Sons, Mr. T. Wilkins was first. The class was for six kinds grown from seed supplied by Messrs. Webb. The winner staged Webb's Masterpiece Onion, Peerless Cauliflower, Sensation Tomato, Goldfinder Potatoes, Duke of Albany Pea, and Market Favourite Carrot (grand). Mr. C. Foster was second with Early Mammoth Cauliflower, Talisman Peas, Regina Tomato, Masterpiece Onion, Progress Potato, Mammoth Red Celery; and Mr. Read third.

Miscellaneous Exhibits.

Messrs. Dicksons, Ltd., Chester, filled the whole of one large tent with a splendid exhibit, well worthy of this noted firm. Down the centre were arranged graceful Tree Ferns, and tastefully placed around were groups of Tea Roses, beautiful Liliums in variety, Cannas, Hydrangea paniculata grandiflora. There was a fine group of Palms, a grand specimen of Phœnix reclinata occupying the central position. Begonias were also very fine, the flowers being of good substance and size. Other groups were composed of choice Carnations, Romneya Coulteri, Crotons, and Dracænas rising from a groundwork of Ferns; while Caladiums, Pancratiums, Chrysanthemums, Streptocarpus, seedlings and others. Around the sides were a fine cross and anchor, bouquets of Carnations, graceful baskets of Roses, beautiful vases of Sweet Peas, charming Carnations, with a splendid exhibit of hardy border flowers, amongst which were noted Gladiolus The Bride, Calendula Prince of Orange, Pentstemon Ardent, Helianthus rigidus, Centaurea montana rubra, Phlox Queen Victoria, Gladiolus delicatissima, Sidalcea candida, and many others. Vines in pots, lawn grass in a large box, and Potatoes complete the whole of this grand exhibit, for which the gold medal was awarded.

Mr. N. F. Barnes, gardener to the Duke of Westminster, arranged a magnificent group of Souvenir de la Malmaison Carnations, the greater part in 48-size pots, numbering altogether some 300. The group was edged with Adiantum cuneatum and Panicum variegatum. A gold medal was awarded this exhibit.

Messrs. Cowan, Liverpool, were awarded a silver medal for a very fine group of Tea Roses and Liliums. Silver medals were also awarded to Messrs. R. Wallace & Co. for a fine exhibit of Liliums in variety; Messrs. Eckford, Wem, Shropshire, for superb Sweet Peas; Messrs. R. Hartland & Son, Cork, for eight boxes of Begonias, all double, the blooms being grand in size and substance; Mr. Ed. Murrell, Shrewsbury, for Roses; Mr. Henry Brownhill, for fine hybrid Chrysanthemums, choice Begonias, Dahlias, Tomatoes, and Peas; and to Messrs. W. & J. Birkenhead, Sale, Manchester, for a choice assortment of Ferns. Mr. M. Campbell, High Blantyre, staged charming single hybrid Chrysanthemums of fine substance, also beautiful Pansies, for which he received a bronze medal.

HUYTON AND ROBY.—July 29th.

On Thursday last, in perfect weather and in the midst of a fashionable assembly, Alexander Mackenzie Smith, Esq., Bolton Hey, Roby, opened the annual Show of the above Society. Of the exhibits nothing but the highest praise could be bestowed.

For four stove and greenhouse plants, four Ferns, four Caladiums, two Liliums, two Palms or Cycads, three Coleus, two and one Orchid, single stove plant in flower, single Caladium, single Fern and six Cockscombs, Mr. R. Pinnington, gardener to Mrs. Banner, Blacklow House, Roby, secured first prize in each class with plants of excellent quality throughout. In many of the classes he was closely followed by Mr. Jno. George, gardener to Mrs. Ihler, Huyton Hey House, Huyton, a persevering young gardener who has made much progress during the past year. This exhibitor also won with Fuchsias, table plants, one Caladium, and one fine-foliage plant. Mr. W. Lyon, gardener to A. Mackenzie Smith, Esq., secured the prize for a group 9 feet in diameter, the arrangement reflecting the greatest possible credit. Mr. Pinnington was a good second. Mr. Lyon was also successful in several other classes, securing a special for a hanging basket, also for Petunias. Mr. E. Bridge, gardener to Mrs. Jowett, Huyton, was well to the fore with handsome Zonal Pelargoniums and for one Begonia. Mr. T. Eaton, gardener to Jno. Parrington, Esq., Roby Mount, Roby, secured a first for four well-flowered tuberous Begonias, Mr. Lyon following very close.

The table decorations—for ladies only—were most attractive, and formed a pleasing contrast to the plants. Mrs. Middlehurst secured the first prize with a light arrangement of Sweet Peas and Gypsophila elegans; followed by Miss Clara Arthur with a similar arrangement, but a trifle too heavy; and Mrs. Parrington with a handsome arrangement of pink Carnations and fragile Grasses. Miss Arthur also won with a charming bouquet, and Mrs. Parrington with a lovely centrepiece. Miss Appleton took the prize for basket of Roses; Mrs. Middlehurst for ladies' spray; and Mrs. F. A. Green and Mr. R. Pinnington equal first for gentleman's buttonhole.

Other winners in cut flower classes were Messrs. W. Oldham (gardener to Joseph Beecham, Esq., Ewanville, Huyton), T. Eaton, J. Humphreys, and J. A. O'Connor. There were four competitors for eighteen cut Roses not less than twelve varieties, and Mr. R. Pinnington somewhat easily secured the special prize offered with blooms of good form and substance. Mr. J. Burrows, gardener to W. H. Crook, Esq., Huyton, was an easy first for twelve distinct, and Mr. T. D. Syers for six distinct. Other cut flowers in amateurs' and cottagers' classes were very fine.

Fruit was not of the highest quality, Mr. Eaton, however, winning the four dishes with good Black Hamburgh Grapes, Hero of Lockinge Melon, excellent Violette Hâtive Nectarine, and fine Peaches; Mr. Pinnington second. Mr. Eaton was well to the fore for Peaches and Nectarines, and a fine dish of Latest of All Strawberries. In all Grape classes Mr. W. Oldham was triumphant, Messrs. Eaton and Pinnington following.

Vegetables were fair, Mr. Lyon taking the collection for French Beans and three dishes of Tomatoes; Mr. Pinnington four dishes of Potatoes and Cauliflowers; and Mr. Humphreys Cucumbers.

The Countess of Derby's special—a handsome striking clock—for the best kept cottagers' garden was taken by Mr. John Lyon, who also won the cottagers' collection. To Mr. Airey (Treasurer), Mr. H. Middlehurst (Secretary), the stagers and Committee, the highest commendation is to be given for their admirable arrangements. The attendance was very good.

LIVERPOOL.—July 31st and August 2nd.

On Saturday and Monday last the seventeenth annual Show of the above Association was held on the review ground, Sefton Park. The Committee had every reason to be proud of the exhibition of plants, fruits, and vegetables, which completely filled the handsome and commodious tent and its annexe, and made a striking impression upon all present. The plants were the chief feature, and we never remember them being better shown.

In the class for ten stove and greenhouse plants, five of each, Mr. B. Cromwell, gardener to T. Sutton Timmis, Esq., Cleveley, Allerton, had an easy win, his plants being marked by the stamp of the highest cultivation. Mr. J. Bracegirdle, gardener to W. H. Watts, Esq., Elm Hall, Wavertree, was placed second; and Mr. R. Pinnington, gardener to Mrs. Banner, Blacklow House, Roby, third. For six stove and greenhouse plants Mr. G. Leadbetter, gardener to W. J. Davey, Esq.,

Holmleigh, Aigburth, won. For six stove and greenhouse Ferns Mr. J. Pattison, gardener to S. J. Waring, Esq., Palmyra, Aigburth, took leading honours; Mr. T. Gowen, gardener to G. A. Bartlett, Esq., Mossley Hill, a good second. Mr. Pattison also won with one fine Palm and two Liliums.

For four fine-foliage plants Mr. Pinnington won, Mr. Bracegirdle came a good second. Mr. Pinnington also secured classes for three greenhouse plants in flower, three Palms or Cycads, six Cockscombs, and second to Mr. Cromwell for six Caladiums. Mr. Gowen won with a nice piece of Dicksonia squarrosa in single Tree Fern, and Mr. Cromwell for other single with a champion plant of Davallia fijiensis plumosa. The latter exhibitor also won classes for six Crotons in 8-inch pots, six Dracænas beautifully grown, one stove plant in bloom, a fine Ixora Pilgrimi, six table plants, also for one foliage plant, with a grand Croton mortfontainensis.

Zonal Pelargoniums were better than for many years, Messrs. E Bridge, gardener to Mrs. Jowett, Greenhill, Huyton, T. Hitchman, gardener to Arthur Earle, Esq., Childwall Lodge, T. Gowan, and G. Bracegirdle being the successful ones. Mr. Hitchman won with four Coleus. For three Ferns and four pans of Lycopods, Mr. F. Field, gardener to G. H. Wilson, Esq., was adjudged the winner, whilst for Gloxinias and tuberous Begonias a well-known grower, Mr. T. Ankers, gardener to W. B. Bowring, Esq., was well ahead. Mr. Bracegirdle had handsome Fuchsias, winning in each class, also for a single groenhouse plant.

Orchids were a distinct advance on former years, Mr. E. Taylor, gardener to E. Pryor, Esq., winning with superb plants of Cattleyas Gaskelliana, guttata Leopoldi, Aërides crispum, and Oncidium sarcodes; Messrs. Bracegirdle and Pinnington following with good exhibits. In the class for two cool house Orchids, Mr. T. Wilson, gardener to O. H. Williams, Esq., Fulwood Park, Aigburth, had a fine type of Oncidium crispum and a creamy-white Lycaste Skinneri without a trace of colouring. It was rightly named "Cowan's variety," both plants having been imported by the firm of Jno. Cowan & Co., Ltd., Garston and Gateacre, from whom so many good things have come.

The groups were effectively arranged and greatly admired, that for space not exceeding 250 square feet being taken by Mr. Bracegirdle with a most pleasing arrangement, showing more than ordinary skill in every detail. Mr. T. Coulton, Aigburth, was second. For those not occupying more than 75 square feet Mr. H. McFall, gardener to E. C. Leventon, Esq., Oakfield, Roby, was an easy first, light and elegant to a degree. A nice second group, taking the form of a miniature dell, and which would have been greatly enhanced by the substitution of fresh green moss in place of sphagnum, was taken by Mr. Whittle, gardener to R. G. Allan, Esq.

Mr. T. Carling, gardener to Mrs. Cope, Dove Park, Woolton, was deservedly awarded the prize for four Tomatoes grown in pots not exceeding 12 inches, one plant in each pot, for grand specimens literally roped with fruit of the largest size, and free from every trace of disease.

Roses were in excellent condition, Messrs. Alex. Dickson & Sons, Newtownards, co. Down, easily securing the prize for forty-eight distinct, with lovely flowers, and here again this firm surprised and delighted many rosarians by the charming new varieties they included. Messrs. D. & W. Croll, Dundee, took second position with an effectively arranged stand containing some fine flowers; Mr. Hugh Dickson, Belfast, was third. For eighteen Teas and Noisettes, Messrs. D. & W. Croll secured the leading position with an excellent stand; Messrs. Alex. Dickson & Sons were a very close second, and Mr. Hugh Dickson a creditable third. Messrs. Alex. Dickson & Sons won for six dark and light varieties with Ulrich Brunner and Marchioness of Dufferin.

Three exhibited for best and most tastefully arranged box of Roses, and Mr. P. Greene, gardener to Thos. Gee, Esq., Allerton, carried off the prize with a delightful stand arranged with fern, Crimson Rambler showing to great advantage. In the amateurs' classes, Mr. T. Carling won with twenty-four, and Mr. Carron, gardener to T. R. Bulley, Esq., Liscard, with twelve.

Mr. Thos. Coulton, nurseryman, Aigburth Vale, secured the prizes for twenty-four and eighteen varieties of hardy herbaceous and half-hardy border flowers with fresh and diversified samples, and Mr. Carling had one of the finest stands of stove and greenhouse cut flowers ever seen at any Liverpool show.

The fruit classes were only sparsely filled, Muscats being a little under-ripe, but fine in bunch and berry. The first went to Mr. J. Gray, gardener to Sir G. A. Meyrick, Bodorgan; and the second to Mr. W. Oldham. Mr. Skilt, gardener to Mrs. Heywood Bright, Knotty Ash, won with two massive Black Hamburghs, a close second being Mr. Oldham. For four bunches Mr. Elsworth, gardener to Messrs. W. L. and R. F. Gladstone, won with small but well finished Madresfield Court, Buckland Sweetwater, Black Hamburgh, and Muscat of Alexandria. Mr. Oldham had more massive bunches, but scarcely so well finished.

Mr. B. Ashton won the collection with fair Black Hamburgh and Muscat of Alexandria Grapes, Royal George Peaches, Lord Napier Nectarines, a capital Melon, and Brown Ischia Figs. Mr. Elsworthy was an excellent second. For four dishes Mr. T. Eaton, gardener to Jno. Parrington, Esq., Roby Mount, Roby, was the only exhibitor, but the stand was a creditable one. Mr. J. Stephenson won with Peaches, and Mr. G. Leadbeater with Nectarines, Mr. Eaton following in each class.

Vegetables were very good, Mr. J. Rainford, Prescot, winning the twelve class, Mr. Ashton second. Mr. John Pownall, Prescot, won with eight, and Mr. Ashton with six. The latter won with four dishes of Peas, and Mr. J. Salisbury for two. Potatoes went to Mr. W. Lyon (gardener to A. M. Smith, Esq.) and Mr. Ashton; and Tomatoes to Messrs. Stephenson and Carling. Amateurs' collections were good.

The trade was well represented, the John Cowan Company, Limited, Garston, having a lovely bank of Roses, Liliums, and fine tuberous Begonias. Their collection of Orchids was rich in variety and splendidly flowered—one of the best tables they have ever staged, and much admired. Messrs. W. Clibran & Son, Altrincham, were represented by a large, excellent, and varied exhibit, consisting of herbaceous cut flowers, Sweet Peas, and other annuals, Carnations, and a pleasing assortment of Violas, all well put up and most attractive.

Dickson, Limited, Chester, again came forward with one of their fine exhibits, consisting of a splendid assortment of Liliums and Gladioli, Helianthus in variety, thirty varieties of Sweet Peas, and some choice seedling Carnations. Messrs. R. P. Ker & Sons, Aigburth, staged grand Crotons. Their group of Campanulas was a striking feature of the show. Mr. Chas. Young showed Carnations of the finest types and Lily of the Valley. Mr. Septimus Pye, Garstang, had an unusually fine display of Violas in every shade and colour. Messrs. Edwards & Son, Sherwood, Notts, had a charming exhibit of the now famous Edwardian ware. The officials are deserving of every credit in their share of the work.

Certificates of merit were granted to all the trade, also to Mr. Doe, gardener to the Right Hon. the Earl of Derby, K.G., for handsome seedling green-flesh Melons, beautifully netted, the flesh being extremely thick, and to Mr. Hitchman for a seedling yellow Tomato of perfect form, no eye, and very weighty.

SOUTHAMPTON.—July 31st and August 2nd.

Circumstances, over which the Royal Horticultural Society of Southampton have no control, have very much altered the conditions under which the Council labours. To some of our readers it will be within their knowledge that the Council obtained a lease of the lovely grounds of Westwood Park, adjacent to the town, and where fourteen admirable summer exhibitions were held. Failing to obtain a renewal of that lease the Council this year was compelled to seek the aid of the Corporation of the Borough to allow them to enclose a few acres of the Common wherein to hold the Show for the present year. Here, then, the meeting was held on what was apparently a suitable site. Owing to bad weather the finances are not at present in a satisfactory condition. The schedule had to be cut down in the number of its classes, and in the amount of its prizes. In spite of all these drawbacks the exhibition held was an exceedingly good one, ranking amongst the best yet held by the Society in point of quality of the exhibits. Such a fact is creditable to all concerned. Nowhere are exhibitions conducted with more efficiency. The arrangements in the capable hands of the indefatigable Secretary, Mr. Fuidge, are always of the best.

One immense marquee was devoted to plants, and a really grand effect was produced. The principal class was for eight stove and greenhouse specimens, four to be in bloom the remainder foliage. Although only two competed they were a creditable display. So close in point of merit were the specimens that equal first prizes were awarded. Mr. E. Wills, nurseryman, Winchester Road, Shirley, Southampton, had superior flowering plants, while Mr. Peel, gardener to Miss Todd, Sibthorpe Lodge, Shirley, was stronger in foliage. For six miscellaneous plants, not less than three to be in bloom, there was a spirited competition, Mr. Osman, gardener to Mrs. Haselfoot, Bitterne, was the chief prizetaker with good examples of cultural skill, amongst which was a freely flowered Allamanda grandiflora. Mr. J. Amys, gardener to the Hon. Mrs. Elliott Yorke, Hamble Cliff, was a good second. Mr. Wills was a creditable third.

Ferns were a feature of the show. Mr. G. Hall, gardener to Lady Louisa Ashburton, Melchet Court, Romsey, was an easy winner for six with healthy specimens. Messrs. Osman and Amys were second and third respectively in the order here given. Pelargoniums, double and single, Fuchsias, and Celosias were creditable to all. Mr. Osman; Mr. Hosey, gardener to J. C. E. D'Esterre, Esq., Elmfield Hill, Sonthampton; and Mr. R. C. West, gardener to H. G. Wigram, Esq., Northlands, Salisbury, were the principal prizetakers. Single specimen plants were excellent. In flowering plants Mr. Amys presented one of Allamanda Hendersoni, which he knows so well how to cultivate; Mr. Wills with Cycas revoluta winning premier award in the foliage class with a really handsome piece.

Groups of miscellaneous plants arranged for effect were very fine. Three competed in the class of 150 square feet. Mr. Peel just managed to beat his worthy opponent Mr. Wills with an arrangement that left little to be desired. The group was bright and varied without being in any way crowded, while the plants were just what was required for the purpose. Mr. Wills, if anything, erred on the side of dullness. Mr. E Carr, gardener to W. A. Gillett, Esq., Fairoak Lodge, Bishopstoke, was a creditable third. In the smaller group Mr. H. Andrews, gardener to Mrs. R. F. Wilson, Ferniehurst, Rowsham, was the most successful with a creditable exhibit.

Cut flowers were extensively shown, and with a pleasing effect. Table decoration was a strong feature of this section. For the most elegantly dressed table, 8 feet by 4 feet, with flowers and foliage, a very strong competition was forthcoming. Mr. B. Ladhams, Shirley, was ahead of all others with a light yet bright arrangement of suitable flowers. Miss Kate Golding, Portswood, was a good second, and Mr. B. Small, Fair Oak, Eastleigh, third. The best epergne was that from Miss Lonise Wills, Shirley; while the best ball and bridal bouquets were sent by Mr. F. Bailey, florist, Southampton.

For twelve bunches of herbaceous flowers, distinct, there was a spirited

competition. Mr. B. Ladhams was an easy winner of the premier place with a handsome collection—Rudbeckia purpurea, Tritoma glaucescens, Gaillardia and Phygelius capensis. Mr. Wilcox, gardener to Col. Sinkins, Aldermoor, Shirley, second. Cactus and other Dahlias were well shown. For twelve Cactus varieties, Messrs. Keynes, Williams & Co., Salisbury, first, as also were they for twelve bunches Pompon varieties.

Fruit made a fine display. For six dishes, Pines excluded, there were five competitors. Mr. G. A. Inglefield, gardener to Sir J. Kelk, Bart., Tedworth, Marlborough, won first prize with dishes of good quality. Muscat of Alexandria and Black Hamburgh Grapes, Hero of Lockinge Melon, and excellent Pineapple Nectarines were the principal dishes; Mr. A. Henbest, gardener to A. Kennard, Esq., Crawley Court, Winchester, second; Mr. W. Mitchell, gardener to J. W. Fleming, Esq., Chilworth Manor, third. Grapes were extensively staged. For three bunches of Black Hamburgh five competed. Mr. Mitchell, with bunches weighing 4 lbs. each, was easily first; Mr. G. Newman, gardener to Captain Gaussen, Twyford Lodge, Winchester, second; Mr. Inglefield third, all staging extremely well. For the same number any other black variety Mr. Mitchell was again successful with Madresfield Court in splendid condition; Mr. Chester, gardener to Sir W. Pink, Shrover Hall, Cosham, second with the same variety; Mr. G. Hall was third.

Muscat of Alexandria was fairly well represented. For three bunches Mr. Inglefield was first. Mr. G. Hall had the best any other white variety with Buckland Sweetwater, Mr. Chester second. Mr. Wilcox won for two bunches black, with creditable examples of Black Hamburgh. Mr. Hygate, gardener to S. P. Munford, Esq., The Briary, Cowes, took a similar position for any white variety. Mr. Mitchell, with Sutton's Imperial Green Melon, was the most successful in a strong class. Mr. Mitchell also had the best dish of Peaches—Dymond. Mr. J. Budd, gardener to R. F. Dalgety, Esq., Lockerby Hall, Romsey, staged fine Elruge Nectarines, for which he was awarded premier position. Hardy fruit in six dishes was a strong class; Mr. Budd, with July Gage Plum, Cherries, Gooseberries and Apricots was first, Mr. West second. Vegetables were staged in large numbers and of good quality. In the special classes provided by Messrs. Toogood, Webb, and Sutton, Mr. T. Wilkins, gardener to Lady Theodore Guest, Inwood House, Henstridge, secured all the premier awards with excellent examples of well known varieties.

Mr. W. H. Rogers, Red Lodge Nurseries, Southampton, had an excellent assortment of shrubs in pots; Mr. Ladhams a charming collection of cut herbaceous flowers, making a bright, varied, and pleasing display. Both of these exhibits were "not for competition." Mr. Foster, Brockhampton, staged a large collection of Sweet Peas in bunches tastefully arranged, and which were a conspicuous feature of the show.

THE YOUNG GARDENERS' DOMAIN.

Our Wild Flowers.

On the chalk hills of North Herts we are especially favoured with a great variety of wild flowers. This is observable by the admirers of these flowers who have the privilege to dwell here and observe them. At the south end of our village the chalk forms the subsoil, and the top layer is of a stiff loamy nature. Here the flowers appear to be absent that abound at the north end, where the chalk rises to the surface and forms the upper layer, so that the fields have quite a white appearance. Not only are flowers found by the wayside, but we have woodlands where acres of Primroses and Bluebells appear in their season, as well as Orchis and other flowers.

In walking distance we have the bleak hills of Royston Heath, where I have gathered the Pasqueflower, Anemone pulsatilla, in early spring. The main road which runs through our village is an old Roman road, through which in times gone by the stage coach used to travel on its way from London to Cambridge, now much frequented by cyclists. The keeping of this splendid road is under the care of the C.C., who also keep the waysides neat and trim. It is here we miss the nodding heads of our favourites, and mourn their absence. How different is it when we turn into a byway over which the C.C. have no control. Here we find the waysides bedecked with various kinds of flowers, in diverse forms and colours. We linger amongst them, gathering a few here and there to take home for further thought and admiration. We are between banks from 6 to 7 feet high, the whole a mass of flowers, and as associated with various kinds of grasses present a most pleasing appearance.

Many practical lessons might with advantage be learnt from some of these flowers by introducing them into our herbaceous borders. I often feel ashamed of my ignorance concerning the names of these flowers, but I mention those of a few I remember as growing there. Knapweeds, Agrimony, Yarrow or Milfoil, Sainfoin, Kidney Vetch, yellow and white Bedstraws, Ragwort, Wild Thyme, Restharrow, Wild Carrot and Parsnip, Harebells, with other Campanulas. All the above with many others adorn the banks in question.

We had this past week twelve children in the village from the great metropolis for a breath of fresh air. Their liberty was not long obtained before their hands became filled with wild flowers, grasping them with such delight that is never seen amongst our native children; their small white hands forming a striking contrast to the glowing colours of the Poppies. The old people with whom these children lodge are often put to difficulty where to place the flowers now being constantly brought home. I notice by the schedules of our local flower shows that prizes are offered for the best correctly named collection of wild flowers; this is a good sign, at least so thinks—Nil Desperandum.

Luculia gratissima.

Luculia gratissima deservedly holds a foremost place amongst wall and pillar plants in greenhouses suitable for its cultivation, the fragrant blooms of delicate colour coming into full beauty in autumn. Although this plant will succeed to some extent under pot culture, it very much prefers a border, rather shallow, well drained, and composed of turfy loam, peat, and sand. By allowing three or four leads to run up the required height, and working upon the spur system, abundance of flowers are obtained, which, however, do not lend themselves readily for house decoration, as they do not long remain fresh after being cut.

Propagation is difficult to effect, as the seeds are seldom, if ever, produced in this country, and cuttings are often very shy in rooting. Only the young tips of the shoots, not more than an inch in length, seem to have any chance at all. These must be inserted in sandy compost under a bell-glass, with gentle bottom heat, taking care not to allow much moisture to accumulate upon the leaves, as they are very liable to damp off. Three or four weeks should see the successful ones rooting, and these may be potted very carefully, and kept in a close shady atmosphere until thoroughly established.

There is another variety, L. Pinceana, which blooms in the summer, flowers white and even more fragrant than L. gratissima, but it does not appear to be so popular, probably because there are plenty of attractive objects at the same time.—R. A. Anderson, *Alnwick*.

[We are much obliged to our correspondent for allowing three-fourths of an inch of space between the lines. It is very convenient to editors and compositors who spend their days and half their nights in poring over MSS.]

Manures for Vines.

The query of "W. H. T." on Madresfield Court Grape not colouring in your issue of July 22nd has suggested to me the writing of this note. In the vineries, in which I am specially interested, black Grapes were always wanting in colour (Cooper's Black excepted), though the bunches and berries were above the average in size. The borders are outside and cemented at the bottom and sides, so the roots cannot ramble.

The staple article used in their formation is the top spit of a deer park cut into lumps 3 or 4 inches square, adding a good sprinkling of bonemeal and half-inch bones as the border is made. Leaf mould is sparingly used. We add a section from 4 to 6 feet each year till the border is completed if the Vines have grown freely, otherwise only a fresh piece is added every second year. The loam is supposed to be over limestone, which is plentiful. White Grapes do well in such a border. Muscats finishing admirably, and are extra large in bunch and berry. Buckland Sweetwater, Foster's Seedling, and Golden Queen also succeed well, the last named being nearly free from that muddy appearance it so often shows after hanging for some time.

Wanting the bunches for exhibition made me anxious to colour the black Grapes, and so I experimented with some artificial manures, also farmyard manure. A couple of years ago I tried dressings of nitrate of soda, superphosphate of lime, and kainit mixed, fortnightly, watering in with clear water, but with no good results as regards colour. Last year I added muriate of potash in place of kainit, and gave a light dressing every week, and the season being dry watered well in with liquid cow and sheep manure, with a little soot added occasionally.

It was interesting to watch the results of such high feeding on several varieties. Mrs. Pearson was small in berry, and of a dirty green colour; Appley Towers small and not well coloured; Buckland Sweetwater swelled very large berries, some of which cracked, but of a beautiful amber colour; Madresfield Court had fine bunches and berries, but there was no improvement in the colour, few of the berries finishing to the footstalks; Mrs. Pince and Black Hamburgh were worse in colour, a like remark applying to Alicante, Gros Colman, and Black Morocco.

Knowing that Vines must have a good supply of nitrogen and potash in the soil to colour the fruit, I next tried manures rich in such. Last autumn I top-dressed with sulphate of lime (gypsum) at the rate of three-quarters of a pound per yard, forking it in lightly, the roots being close to the surface. Though lime may be in the loam, it may still not be in available condition as plant food till rendered so by some alkaloid. Afterwards a dressing of dissolved bones and sulphate of potash was given. When the buds started I top-dressed with a mixture composed of superphosphate five parts, nitrate of potash three parts, sulphate of iron and sulphate of magnesia one part each, repeating after setting, and again after stoning, and the season being showery little watering was required, and clear water only used.

All the black varieties now ripe are decidedly better in colour and finish. Mrs. Pearson is also much improved in size of berry and colour. Appley Towers and Black Hamburgh are very large, and as black as Damsons. Mrs. Pince, Gros Colman, Gros Guillaume, and Alicante are colouring fast, and looked like finishing well. No fault can be found with Madresfield Court, except an odd berry cracking, which must be expected when the house is used for plants, and the fruit is now nearly coloured to the footstalks.

I will write again when all are finished, and also give the results of different stocks I have tried for varieties which are difficult to finish, or are shy setters. The White Muscats all seem to have been improved, colouring earlier than other years. No leaves are turning brown around the edges, as sometimes happens, but are deep green and large, though no shade is ever applied, and the Vines are cropped heavily.—W. T., *Ireland*.

[Not young gardeners only will be obliged to our correspondent for the records of his experiments.]

FRUIT FORCING.

Cherry House.—The trees that were started early in the year are ripe in wood and plump in bud. The leaves, too, will not be capable of much further effort in elaborating the sap, and storing it in the buds and adjacent wood; therefore any undue excitement will cause the trees to start into growth, which must be guarded against by exposure to atmospheric influences as far as the house will admit, which is the best means of averting premature growth, to which the Cherry is liable when forced year after year successively. The border must not be allowed to become parchingly dry, but have a copious supply of water when necessary for keeping it a moist condition; and if the trees are weak afford liquid manure. To subdue red spider give an occasional washing with the garden engine or syringe, and if needful apply an insecticide, but by all means remove the roof lights, the cleansing influence of rain and invigorating tendency of dew, with the thorough moistening of the border, having a very beneficial effect.

Black aphis can hardly be kept from Cherry trees for any length of time, but the leaves and wood at this season, from their hard texture, are not inviting to them, yet if they appear on the laterals promptly use tobacco water, or dust the affected parts with snuff or tobacco powder. The narcotic is fatal to these somewhat hardly-killed insects, and it deters egg deposition on the young shoots. Cherry trees in pots are the most interesting of all fruits grown that way. They offer such a variety and afford fruit over so long a period that it is remarkable they are not more commonly seen. With very slight forcing they ripen the crop in May, and afford a succession up to August. In a house without heat, but light and well ventilated, ripe Cherries can be had early in June, and a succession may be maintained, with proper care, up to September, inclusive. Early Rivers, Empress Eugénie, May Duke, Archduke, Governor Wood, Black Eagle, Emperor Francis, Florence, and many other varieties are excellent. For planting out Early Rivers, Elton, Governor Wood, and Black Tartarian afford good crops of large fruit. Trees in pots must be regularly watered and syringed to maintain the foliage in health as long as possible.

Figs.—*Earliest Forced Trees in Pots.*—Directly the second crop of fruit is gathered examine the trees for red spider and scale, as keeping the soil somewhat drier at the roots, and the atmosphere being drier in consequence of a free circulation of air, these pests increase alarmingly. They are almost certain infestors of Fig trees in heated structures, and however alert the cultivator may be these enemies get ahead during the ripening of the fruit; therefore, when that is cleared off the trees recourse must be had to cleansing, and as the foliage and wood is far advanced in ripening destructive agents may be employed at a strength that would not be safe at an earlier stage.

If, therefore, these pests have made undesirable progress it will be advisable to syringe the trees with an approved insecticide or a mixture of petroleum, softsoap, soda, and water. One wineglassful of petroleum to 4 gallons of water, in which 8 ozs. of softsoap has been dissolved, with 1 oz. of washing soda whilst boiling, should be stirred briskly with a broom-handle whilst another person applies it to the trees with a syringe so as to wet every part of the tree, the under as well as the upper side of the leaves and all the wood. To prevent the mixture soaking into the soil a little dry moss may be tied round the stem, and then a sort of pyramid of the same placed about the plants. If the wood is badly infested employ a somewhat stiff brush for freeing it of the scale whilst wet. In bad cases repeat this in the course of a day or two, afterwards syringing thoroughly with tepid water. The trees will only need water to prevent the foliage becoming limp, ventilating to the fullest extent day and night; but protect the trees from heavy rains, which have a tendency to growth instead of securing that rest essential for those subjected to early forcing.

Early Forced Planted-out Trees.—As the second crop is ripening a circulation of air will be needed constantly, more of course by day than at night. If dull, wet weather prevail, a gentle heat in the pipes make all the difference between well ripened and insipid fruit. It also often makes impunity or otherwise from "spot," certain or uncertain. Watering at the roots must be diminished, and syringing discontinued, but a moderate air moisture may be maintained for the benefit of the foliage. If red spider is present, and there is heat in the hot-water pipes, coat these thinly with sulphur, or a good syringing may be given after the fruits have been picked close, choosing a time when there is a prospect of the moisture not remaining long upon the trees. As soon as the fruits are all gathered the trees may have a good washing with the syringe or engine to free the foliage of dust and red spider, otherwise a free circulation of dry warm air should be maintained in the house until the foliage commenced falling naturally, and which must not be accelerated by allowing the soil to become dust dry at the roots.

Unheated Houses.—When Fig trees are grown against walls the crops are not always satisfactory, especially in a wet season, but covering such trees with glass usually results in the produce of Figs of the highest excellence. Structures with a south aspect are the most suitable, and to have the trees thoroughly under command the roots must be restricted to narrow borders, one-third the width of the trellis being ample, and not more than 2 feet deep over plenty of drainage of a calcareous nature. The border may consist of good substantial loam with about one-fifth of old mortar rubbish incorporated. The calcareous matter is essential to the formation of nitrate of lime in the soil, and sand is an important constituent in building up the structure of the trees. With unobstructed light and provision for free ventilation the finest Figs may be obtained if the usual attention is given to feeding with liquid manure as required. It is also necessary that the growths be thin, acting on the extension system, but securing by judicious stopping a fair amount of spurs, and in no case allow more growths to be made than can have full exposure to light. The fruit is now advanced in swelling, and every pains must be taken to keep the foliage free from red spider. This may be effected by forcible syringing early in the afternoon, but do not syringe it if there is no prospect of the foliage becoming dry before night. Under such circumstances damp the border, especially in the afternoon, and occasionally with liquid manure.

Admit a little air early, increasing it with the sun heat, maintaining through the day a temperature of 80° to 85°, with free ventilation, closing early, so as to run up to 90° or 95°, even 100°, and when the sun is declining a little air may be admitted at the top so as to allow the pent-up air moisture to escape, the temperature gradually cooling down. Water or liquid manure, according to circumstances, will be required about once a week or oftener, in order to keep the soil in a properly moist condition. When the fruit begins to ripen lessen the supply of water and discontinue syringing, securing a circulation of air constantly, and freely ventilate when favourable. Husband sun heat, which will not do any harm if the atmosphere is not confined, a little ventilation being given so as to allow of the moisture escaping instead of condensing on the fruit and causing it to crack and mould.

Pines.—*Cleaning Houses and Beds.*—Cleanliness is essential to health and high-class produce. Bottom heat promotes certain and speedy work in Pine culture, hence the first thing to be seen to is the bed. If the bottom heat be afforded by hot-water pipes the material forming the bed, whether of tan or leaves, should be removed at least once a year, or insects, particularly woodlice, rapidly increase, the material also harbours other predatory vermin. All brickwork may be scalded and brushed with hot limewash, the wood and ironwork thoroughly cleansed with soap and water, using a brush, keeping the soapy water as much as possible from the glass, which should be cleansed inside and outside with water only. If necessary the wood and ironwork may be painted, and the roof made as watertight as possible. Beds that are chambered, having hot-water pipes covered with slate or other material, are much in advance of those surrounded or passing through beds of rubble. Those composed of the latter should be turned over, and any dirt or small parts removed to allow the heat given off by the hot-water pipes to penetrate evenly through the whole to the bed. Provide fresh tan in other cases, and if wet turn it occasionally on fine sunny days. With hot-water pipes beneath about 3 feet depth of tan is ample, more will be needed where such aid is not obtained.

Potting.—Suckers started in June will soon have filled their pots with roots, and must be shifted into a larger size before the roots become closely matted together. Queens should have 9 to 10-inch pots, and those of stronger growth 11-inch pots. Water the plants immediately after potting, and plunge them in a bed having a temperature of 90° to 95°. There is no greater mistake in growing Pines than crowding young plants, as they become drawn and weakly instead of having a sturdy base. Attend to the bottom heat of beds that have been recently disturbed or upset by the removal or replacing of plants, not allowing the heat to exceed 90° at the base of the pots without immediately raising them, as too much heat will disastrously affect Pines in fruit or those having the pots filled with roots.

Examine the plants for watering about twice a week, and maintain a moist, genial, well-ventilated atmosphere. The climatic conditions are now so favourable that Pine plants grow vigorously; therefore discontinue shading, admitting air plentifully when the temperature ranges from 85° to 95°, affording fruiting plants a night temperature of 70° to 75°, and to succession 65° to 70° at night. Reserve, if possible, more suckers for starting at the commencement of September.

THE KITCHEN GARDEN.

Globe Artichokes.—Plants that are pushing up late flowering growths will be assisted by thorough soakings of liquid manure, and the heads will then form a very acceptable dish in many establishments at a time of year when variety is most desirable. Old flower stems ought to be cut down according as they are cleared of heads, their longer retention having a weakening effect upon the plants. Seedlings are now sufficiently advanced to be selected from. Only the very best forms or those with stout flower heads and succulent scales should be saved, those much branching, with small heads and thin, prickly scales, not being worth garden room.

Lettuce.—A late autumn supply of Lettuce may be found acceptable for mixing with Endive in the salad bowl. A warm border should be chosen for this late crop, sowing the seed thinly in shallow drills 9 inches to 12 inches apart. With Cos varieties also sow All the Year Round, Commodore Nutt, Golden Queen, and Early Paris Market Cabbage varieties, and if all do not heart in, the early varieties will most probably do so. A good breadth of border should be sown; no transplanting will then be necessary, and if arranged where the Lettuce can be conveniently protected by frames so much the better.

Mushrooms.—Open-air beds formed now with well-prepared manure and duly spawned should be producing Mushrooms early in

October, and a good succession may result if other beds are made and spawned a month later. Neither peat moss manure, short manure, nor nearly all horse droppings are suitable. All the short stained straw, to the extent of fully one-third of the bulk, should be saved with the droppings from corn and hay-fed horses, and all be thrown into a heap to ferment. At this time of year manure heats quickly and fiercely, and unless the heaps are turned inside out every three or four days the centre becomes dry and mouldy—the result of overheating—and worthless accordingly. The manure ought to be kept just moist by gentle waterings when turned, and in the course of a fortnight it should be sufficiently sweetened and freed of rank heat to admit of a ridge-shaped bed being safely formed of it. If these open-air beds become violently hot after they are made, as they are liable to do if the manure has not been well prepared, they are unfit to produce Mushrooms, and not much need be expected of them if the other extreme is reached and no heat be generated.

Forming the Beds.—Ridge-shaped beds should be formed on a dry hard base where they will not be unduly exposed to cold winds, and where, also, rats and mice can be excluded or kept under. They may be of any length, and should, when completed, be about 2½ feet to 3 feet wide, and 3 feet high in the centre, which ought to be narrowed to a width of 9 inches. Thin layers of well-separated manure should be put together and made solid by beating and trampling, finishing off by combing down the sides and ends so as to give the bed the appearance of having been thatched. The manure at the time ought to be moist enough for it to bind together, but must not be so wet that the moisture can be squeezed out of it.

Spawning and Soiling.—When the heat in the beds has declined sufficiently for the inserted ends of trial stakes kept plunged in the manure to be borne comfortably in the palm of the hand on testing, the time has arrived for spawning. Give the preference to new spawn, break each brick into eight pieces, and insert these flatly slightly below the level of the surface of the bed, and about 8 inches apart each way. Avoid forming deep holes for the lumps of spawn, and take good care to pack it tightly in the manure. The mycelium should commence spreading from the spawn in three or four days, when the beds may be soiled over, but previous to that they should be protected from rains and cold winds. Case over with the best fresh loam procurable to a thickness of fully 1½ inch after it has been well beaten and smoothed over with the back of a spade. There must be no watering and plastering over of the soil, as this is invariably followed by shrinking, cracking, and injury to the bed.

Casing over the bed is sometimes followed by a sudden and dangerous rise in the temperature, the same thing happening with a change from comparatively cool to moist warm weather. It is necessary, therefore, to examine the trial sticks frequently, and in order to obviate the dangers attending a great increase in heat pierce holes through the centre of the ridge with a pointed iron rod, this letting out the confined vapour. As soon as it is seen there is a tendency to an undue lowering of temperature rather than an injurious rise, cover the bed heavily with the longer straw litter saved when the droppings were separated from it.

Winter Tomatoes.—Where a supply of Tomatoes must be kept up nearly or quite all the year round a number of plants should be introduced into a low forcing house, in succession to either Cucumbers or Melons, as soon as possible. The fruit fails to set satisfactorily during the short dull days of the late autumn and winter months, and must, therefore, be secured earlier, ripening taking place slowly all through the winter. It is not yet too late to sow seed. Comet, The Cropper, Ham Green Favourite, as well as others, are suitable for the purpose, and if the plants are raised very thinly in pans on greenhouse shelves they will be sturdy, and move into 3-inch pots without experiencing any perceptible check. These winter crops are best grown near the glass. Plant not less than 12 inches apart in a narrow ridge of good loamy soil, and train to a single stem. The alternative plan of fruiting Tomatoes in 10-inch pots answers well. If prepared in the open, house the plants before wet cold weather sets in, or they may become diseased. If possible arrange the plants on a bed of ashes, and allow them to root out into these, then if the ashes are kept moist the plants derive considerable benefit from the association.

Old plants under glass may be made to produce a good late autumn and winter crop. Lay in young shoots thinly up the stems and over the trellis, and top these beyond the first bunch of flower. Fruit will set freely on these shoots, and if the plants are well attended to at the roots a remunerative crop is the result.

PLANT HOUSES.

Stephanotis floribunda.—Plants that have flowered and made good growth must be fully exposed to the sun. Admit air liberally to ripen and harden the wood. This is the secret of a good supply of flowers another year. Syringe twice daily to keep the plants clean, and do not allow the ends of growing shoots to twist together. If they once get into this confused condition and mealy bug exists upon them it is impossible to keep them clean. In the end they also entail double the labour to remove them from the trellis than would be required to train the shoots properly as they grow. Plants that are root-bound and still growing freely should be supplied with weak stimulants every time water is needed. Where an increase in the number of plants is required it is a good time to insert cuttings. Growing shoots moderately soft, with the soft point removed, root freely in heat under hand-lights. If these are kept in a temperature of 60° they will, if potted, make good plants by the end of next season.

Ixoras.—It is a mistake to shade these plants, they ripen their wood and flower with greater freedom when fully exposed to the sun than when grown in mixed stoves and are shaded. Plenty of cuttings should be rooted, soft-growing ends being selected for this purpose. They should be inserted singly in small pots, as they root quickly in brisk heat. Once they are rooted and will bear full exposure place them on a shelf close to the glass, and transfer when ready into 4-inch pots. These plants, where plenty of heat is at command, are easily grown, and for general purposes they are more effective with one or two trusses of flower in 4-inch pots than plants of a larger size. Plenty of heat and careful watering are needed, but they are not particular about soil, although they do best in peat and sand. We have, however, succeeded in growing them well in equal proportions of loam and leaf mould that has not been heated and coarse sand. During the winter the atmosphere should not be kept too moist or the syringe used over the foliage. The old Ixora coccinea requires the most careful watering perhaps of any.

Begonia semperflorens carminea.—This is one of the best Begonias that can be grown, and it would flower all the year round if allowed to do so. It will, however, flower profusely eight months out of the twelve. Those that commenced in January last have continued to flower up to the present time. These plants should be cut back, keeping them on the dry side until they break into growth, when they may be turned out of their pots and the roots partially reduced and replaced in the same size. They will soon commence growth in a vinery or any structure where a little heat is maintained. Water carefully until they are rooting freely. Cuttings may be inserted singly in 2-inch pots, but it is necessary to select shoots that have an eye at the base. Any of the tops will root, but they only extend and flower, being useless after they are pruned back, unless by accident they force a growth bud at the base. If this is provided when the cuttings are inserted all will go well. This applies to many evergreen and semi-tuberous kinds.

Allamandas.—We saw a fine plant recently, and was told it had ceased flowering. It was growing luxuriantly, but had not a single flower. The reason for this was the plant was crowded with growths, and the house shaded. The growths of Allamandas should be evenly but thinly disposed over the roof of the house, and be fully exposed to the sun. At one time we shaded them during the hottest hours of the day, but have found this practice unnecessary, and they make short-jointed wood and flower more profusely without shade. From three plants not eighteen months old we have gathered fully 500 blooms. Every shoot about 1 foot from where they branch should be full of flower buds. It is necessary after branching two or three times from the base to thin the shoots, and leave only those that are required to furnish the roof. Allamandas should under proper treatment begin flowering when the growths are 18 inches long, and continue as long as water and liquid manure is supplied if they are grown in pots.

THE BEE-KEEPER.

AFTER THE HONEY FLOW.

Except in the Heather districts there will be little honey stored after this date, although to the casual observer this statement may appear incorrect, as there are still numerous flowers to be seen in the fields and hedgerows. The second crop of White Clover is still in bloom. It is, however, not much frequented by the bees, which are well aware there is not much honey to be obtained from that source so late in the season.

The majority of the flowers in the meadows are now over, but many in the garden yield either pollen or honey, on which the bees work freely. Mignonette is one of the best honey-producing flowers at this time, but there are not many districts where there is sufficient space devoted to its culture for the bees to derive much benefit from it. Asparagus is another plant which blooms freely at this season. Although the blooms are small and insignificant the bees are very partial to them. From this source there is doubtless a bountiful supply of pollen obtained, but not much honey. Pollen, however, is an important factor in the hive, as the well-being of a colony largely depends on a good store of pollen. Bees should be encouraged to breed throughout the autumn; and if the weather be inclement, so that they are unable to leave their hive, or if fine, a scarcity of flowers, the young stock of bees will be daily supplied from the stored up pollen, and will be much in advance of those stocks which are not so favourably situated.

Some of the hedgerows are now a mass of Blackberry flowers. If the weather is fine the bees obtain honey from them, but as it is dark in colour it is useless except for the bees to store for present requirements or for wintering. A small quantity of honey obtained from this source will soon spoil a good sample of White Clover honey that may have been previously stored in the hive. Many bee-keepers have found this out to their cost when too late, so it is advisable to extract a good sample of honey as soon as it is properly ripened in the hive.

Another source from which an inferior honey is obtained at this season is the Spanish Chestnut, the honey being thin and watery, with a very unpleasant aroma. There is no mistaking honey obtained from this source, as directly the covering is removed from the top of supers, the sickly smell arising from it is perceptible. I once had a fine sample of honey spoiled in this way owing to the supers being left on the hive a day or two too long, so it is advisable to remove the supers as soon as the honey flow is over.

Honey Fermenting.

What is the cause of fermentation in honey? is a question that is often asked. It is caused by the careless bee-keeper who quite unintentionally, it may be, removes the honey from the hive before it has become properly ripened. Honey after it is gathered from the flowers has to go through several processes in the hive before it is ready to be sealed over by the bees. Bees never make a mistake in this matter. If they have not sufficient storage room in the supers they will store their honey in the brood nest, or in any empty cells within their reach, until the high temperature of the hive has ripened the honey, which in the meantime has evaporated considerably, so that the bees can fill the cells from what has been previously stored in other parts of the hive. It is then sealed over, and is ready for extracting, or for storing in the comb. When honey is coming in freely the bees store it in the first cells that come to hand. The busy worker will remove it during the night to the super, or where it is required.

It will at once be seen the care that is required in extracting honey. If unripe it will ferment, and after being kept for a few weeks or months will be useless, and if disposed of before fermentation is suspected it will have the effect of doing an injury to the bee-keeper's interest. It is advisable to always extract honey, or remove the supers in readiness for extracting purposes, before the bees commence work in the morning. I always practise this plan in my apiary, and am never troubled with fermented honey.

There is less danger of obtaining fermented honey from sections if due care is taken in seeing that all the cells are properly sealed over before their removal from the hive. It is better to allow them to remain on the hive two or three days too long than to remove a day too soon. If the honey is not properly ripened they will soon commence to drip, and no amount of after treatment will prevent it.

Storing Honey.

Bee-keepers, whether in a large or small way of business, will doubtless at this season be in the happy position of having a surplus of honey to store away for future requirements. If in sections the wood should be properly cleaned of any propolis that may adhere to them; a blunt knife is a capital instrument for that purpose. If the wood is at all stained a coarse piece of sandpaper will remove it readily. A mark should then be made on the top of each section, so that they may always be stood in the same position they occupied in the hive, as the cells being built with an upward slope there will then be no danger to be feared from dripping, which would be the case if they were stood the opposite way and some honey remained in an unsealed cell. The sections may then be glazed as advised in previous notes, or be wrapped separately in a piece of paper to keep them from the dust, as however carefully packed dust will often find its way through a small crevice that may be unseen, and is then difficult to remove from the comb. Store in a dry place, a cupboard in a room in which there is a fire often will make a capital place for that purpose if the temperature is kept at about 60°. The honey will not granulate as readily in the comb as it would if placed in a lower temperature.

Extracted honey may be placed in a similar position if granulation is not desired; but if this makes no difference it may be stored in any cool, dry place, and will keep in good condition for several years. Granulated honey is pure; the public are now beginning to realise this fact, and there is now much less difficulty in disposing of good samples of granulated honey than formerly.—An English Bee-keeper.

A HEAVY SWARM.

I had, on the 7th of this month (July) a swarm of bees, the largest I ever saw; weight with skep, 11 lbs.; weight of skep, 3¾ lbs., leaving 7¼ lbs. for the bees. I placed them in a 16-bar frame hive together with a small swarm that I had had a day or two before; placing the interceptory board in the middle; this day, July 26th, I have had to place a crate with twenty-one sections on, as the body of the hive is quite full.

I had a swarm about six years since that weighed just over 6 lbs., and I think that I wrote and informed you of the fact, and at the same time sent the number of bees, as I took the trouble to count ½ lb. of bees that I was obliged to destroy as they had got under the roof, and when the sun was hot the wax and honey ran into the room below.—N. H. J.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," *8, Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Training for Examinations (*Colvile Browne*). — We have received the "List of Successes" which you have forwarded of candidates who, by your aid, have passed the R.H.S. examinations. You have good reason to be satisfied with the results of your endeavours, and not less so by the appreciation of students of your methods of teaching. Such intellectual exercise as you afford to young gardeners is excellent training for them whether they pass in examinations or not, and we consider your terms very reasonable indeed.

Aerial Roots on Vines (*R. S. U.*).—These are usually attributed either to the maintenance of a very moist atmosphere in the early stages of the growth of the Vines, or to the roots in the soil not being able, by their paucity or defect in the border, to obtain the essentials needed by the Vines. In many instances both those causes operate in inciting the emission of the stem roots in question. At the same time we have seen them freely produced by Vines that afforded good crops of excellent Grapes, though the reverse is more frequently the case. Where such roots exist it is a safe plan to let them alone.

Tomatoes in Vineries (*W. S.*).—Tons of Tomatoes are grown in vineries every year, and where the plants have light enough they bear and ripen good crops. When the Vines cover the roof densely (and it is not at all uncommon to find the growth and foliage much too crowded) Tomatoes that may be attempted to be grown under them become drawn, and are of little or no value. We know at this moment of splendid Grapes and excellent Tomatoes ripening in the same house—a three-quarter span. The Vines are not closely planted, and the laterals are as thinly disposed as shown in the illustration on page 101 last week. The Tomatoes cover the back wall of the house.

Gardeners' Pensions (*C., Portsmouth*).—We do not know of a society which grants old age pensions to gardeners other than the Royal Benevolent Institution. An old age pension fund, and an excellent one it is, is established by the London County Council for the gardeners employed in the metropolitan parks which are under that body. An accumulation fund of the monies of members not used in sickness is one of the advantages of the Gardeners' United Provident and Benevolent Institution; but we do not know of gardeners' annual old age pension funds other than those above named. If there are any others we shall be glad to receive particulars of them.

Grapes Colouring Indifferently (*W. H. T.*).—In addition to the farmyard manure you may use during the growing period the following mixture: — Bone superphosphate, three parts; nitrate of potash, two parts; and sulphate of lime, one part, mixing thoroughly and applying at the rate of 2 to 4 ozs. per square yard (1) when the Vines commence growing, (2) as soon as the berries are set or thinned, (3) when the Grapes a quarter to half grown, and (4) as soon as the stoning is completed, always when the soil is moist, washing in moderately. In autumn, or when the Vines are pruned, supply a mixture of native guano, fish meal, basic slag phosphate, and sulphate of potash in equal parts, mixing thoroughly and applying at the rate of 7 lbs. per rod, or 4 ozs. per square yard, pointing in lightly. This we have found very effective.

Chrysanthemum Shoot with Bud Eaten Out (*W. D.*).—The bud in the shoot has been eaten out by some minute grub or caterpillar, but beyond the dirt left by the destructive creature there was no trace of it. There may probably be some further remains of the pest to be found on a close scrutiny of the infested plants, if as we suspect the mischief has been caused by a small caterpillar. If you find a fine silken web anywhere on the leaves there will most likely be a little substance beneath it; finding such please forward intact, and we may possibly tell something more at a later period, or when the moth emerges. The early brood of the grey streak moth (Glutella porrectella) sometimes eat the "hearts" out of the shoots, drawing the leaves together by means of silken threads, and conceal themselves (caterpillars) in the middle of them, one in each shoot, eating out the point. In other instances the common angle shades moth (Phlogophora meticulosa) and the small angle shades (P. lucipa) eat out the centre of the growths. This, of course, is done by the caterpillars, which usually lurk in the ground by day and come out to feed at night, but in the young state they may remain in the points of the shoots during the day. We have not noticed any particular presence of these pests this season, but the weather is suitable for them.

Cucumber Stem Diseased (*H. W. P.*)—We were unable to find any insects in the stem, or anything in the shape of an organism, visible or microscopic, likely to cause the stem to decay. This appears due to what is known as "canker," the tissues being quite brown and destroyed. The roots, as you say, appear all right—at least, there was no micro-organism in them that we could discover. There may have been minute insects on the affected part when it was sent off, but if so they had been so smashed in transit as to be altogether undistinguishable. Oftentimes a minute insect affects the collar of the plant, and so rasps the bark as to cause decay, the remedy for which, and canker, is a drier condition about the stem and rubbing quicklime into the affected parts. The lime will also destroy the small insects if dusted upon them.

"Fysal Hemp" (*S. J. A.*).—You wrote "Henry" so plainly last week that we were misled. We are now inclined to think the word is Hemp, though there is scarcely the ghost of a "p" in it. Please do not regard this as a reproach, as we much fear we write hundreds of words without a good, plain, sensible alphabetical in them, though the compositors seem in some mysterious way to know what we mean. We do not know the particular kind of Hemp, if Hemp it is, that you mention; nor do we know of any other kind of Hemp that we could advise to be grown as profitable for its fibre in the average summers of this country. If any of our readers can speak from experience on the point and help you we shall be pleased to hear from them. As to procuring seed, and the quantity to sow, we know of no firm more likely to supply it, with the requisite information, than Messrs. Vilmorin Andrieux & Co., Quai de la Megisserie, Paris; but we doubt very much the realisation of a fortune from an acre of "Fysal Hemp," or whatever the supposed lucrative plant may be. We have heard of a Sisal Hemp, information about which might be procured from Kew.

Cucumbers Failing (*G. R.*).—The turning yellow of the embryo fruits when an inch long may be the result of (1) Dryness of the soil, not on or near the surface, but where it is contact with the heating chamber (if the bed is over hot-water pipes). (2) An attack of minute nematoid worms (which is more serious). (3) Something unfavourable in temperature or atmospheric conditions. We have known incipient fruits to collapse under all these causes. If you will send specimens as soon as you read this reply, not to Fleet Street, but to the address at the head of this column, they shall be carefully examined. It may be advantageous to give fuller particulars of the case and treatment than can be conveyed on a postcard. Microscopical examinations cannot be made in a day or two, and that is why we like to receive specimens with as little delay as possible with the object, if practicable, of publishing a reply next week. Delay is inevitable when editorial communications are not sent to the address that is prominently given at the head of the first article in each issue of the *Journal of Horticulture*, and of the "Correspondent's" column.

A New Pea (*S. H. Wright*).—We have received the Peas you have sent, as the result of a cross between Sharpe's Triumph (pollen bearer), and Carter's Stratagem (seed bearer). We also note that the reverse crosses proved worthless. We have no doubt your description of the variety as to habit is correct—namely, height 3 to 3½ feet, sturdy, short-jointed, foliage bluish green. The tops sent are certainly stout, short-jointed, and generally the very fine full pods are produced in pairs. The peas, of which most pods contained nine, and several ten, are large and as good in colour as could be desired, and hence the name you have given, "Wright's Emerald." We believe there is an "Emerald Gem" Pea in cultivation, and hence the similarity of names is close. You state the Peas sent had been in a "shop window for two days in the broiling sun," and you ask us, therefore, to "make allowances." Moreover, through having been misdirected (see instructions at the head of this column) another day was lost. As to "allowances," they are never made by judges or examiners. Products are appraised by their condition at the time of inspection. Making "allowances" would lead to nothing but confusion. The Pea, judging by the sample, is a very fine one. We have seen no finer this year. As to quality, when cooked, we can only say it had been prejudiced by the drying and delay. We may say of the Pea that if it would grow as well in gardens generally as it has done in the place of its nativity, it is a promising acquisition, and should be grown in the gardens of the Royal Horticultural Society with other old and new varieties, and if it pass the ordeal with honours you will not regret having sent it there.

Border Carnations (*F. A. S., Somerset*).—The southern slope of sandy soil may be too dry for the well-being of the plants, especially during prolonged hot weather, though the effects of drought may be mitigated by deep culture and mulching with short manure in May. Some of the choice florists' Carnations are too delicate in constitution for border cultivation, but there are plenty of varieties sufficiently robust to succeed in the open ground without any protection in winter. It is important to have sound healthy plants to begin with, and plant soon enough in late summer or early autumn for them to take good root-hold and become well established before winter. The sooner the planting is done the better when the ground is in favourable condition, or, in other words, moist, not on the surface alone, but down to and in the subsoil, and the days are not hot and bright; if such should occur after planting it may be prudent to shade for a few hours with inverted flower pots, removing them long before nightfall. The slightly northern slope would probably be better for the plants, and if you could incorporate with it some dried and pounded clay, spreading an inch or two in thickness on the surface, and mixing it through the mass by careful digging with a fork, it would greatly improve its texture. The subsoil should also be well broken up and enriched with manure, and in all probability ½ lb. of basic slag powder and 2 or 3 ozs. of kainit per square yard blended with the soil before planting would have a beneficial effect; and on the approach of dry weather in spring we have found a dressing or two of salt, 1 to 2 ozs. per square yard, and hoed in of service to the plants, subsequently mulching as above advised. We have not found any advantage in covering the plants as protection against frost—in fact, well constitutioned varieties, well established before winter, need no protection. When the blooms are opening canvas or other appropriate shading preserves their purity and prolongs their season of beauty. As to slugs, no doubt occasional dustings of soot are repugnant to them and beneficial to the plants, taking care not to use it in excess; but we have not found anything so effectual as clear lime water applied through a rosed can an hour after nightfall, as if giving the plants a good watering. The pests are then caught feasting. Day-time applications of anything are of comparatively small use, as the slugs are resting beyond their reach. Many Carnation plants fail through being planted on the eve of winter and very late in the spring.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*M. Davison*).—Though your letter was wrongly addressed it has reached us, but no specimens have come to hand. Read the instructions given above, after which send fresh flowers, and we will endeavour to assist you. (*F. V. C.*).—1, Epilobium angustissimum; 2, Veronica rupestris; 3, Cassinea fulvida; 4, Lilium croceum; 5, Anchusa sempervirens; 6, dead. (*L. A. W.*).—1, Clematis coccinea; 2, Agrostemma coronaria; 3, Veronica decussata; 4, Leycesteria formosa. (*S. M. M.*).—Cactus Dahlias are recognised as florists' flowers, which can only be named by comparison in a large collection.

THE CROPS OF 1897.

HAVING arrived at the beginning of August we are now in a position to see how we stand with regard to the farm crops of this year. Of course devastating storms, like that which has ruined our Essex brethren, may come upon us, or we may have a harvest as long and dreary as was the last, still we can now judge pretty fairly of our roots, and estimate the weight per acre of corn. The correspondents of the "*Agricultural Gazette*" have furnished statistics from their various counties, and as they are all men who know what they are talking and writing about we may feel certain that we may accept their views as correct in the main.

Northumberland comes first in the list. There are from this county eighteen correspondents; three of these speak of the Wheat crop as being good, four as an average, three speak of it as below. We hardly call Northumberland a Wheat-growing district. Of the Oat crop eleven write of it as under an average. Ten speak well of Barley, and as harvest is late in this county there is still time for it to do fairly. Turnips are, as a whole, looking well, but there, as well as in other places, rain is needed. Hay seems to have been fair, and well got. Similar remarks apply to Cumberland. Seeds and meadow hay are reported as magnificent in Westmoreland, but finger and toe has attacked some Turnips. Possibly that land is Turnip sick. Wheat is said to be good in Lancashire, and from Durham a gentleman writes that where phosphate powder was applied to grass the hay crop has been very heavy. The majority of Yorkshire correspondents pronounce Wheat to be good. As this is such a large county the Barley accounts vary, but the general idea is that the crop is an average one. Turnips will generally be good if rain come in time. Where Potatoes are grown they look well—*i. e.*, as a field crop.

The Wheat crop is reported as light and short in the straw in Nottinghamshire, while Turnips appear to be good; but there is a cry for rain. Barley is good on good land; the less said about the other the better. There appears to have been too much rain in the winter for the Wheat plant in Leicestershire, and there is too little now to finish off all crops, Potatoes and Turnips suffering most. Cheshire gives promise of a big Mangold crop, also of a good average yield of Potatoes. Barley is regarded as better than usual in Shropshire, and Mangolds good; but finger and toe and wireworm are at the Turnips, these and pastures being "burnt up." Mr. A. P. Turner says Barley is a full average in Hertfordshire, hay splendid in quality, and Turnips a full plant. Basic slag accounts for some very good Oats in Worcestershire, while Potatoes and Turnips would be good had they a little more moisture. Early sown Barley is the best in Warwickshire and Northamptonshire; this happens nine times out of ten generally, but many people will not believe it.

Wheat is reported as thin in Lincolnshire, but Barley promises to be an average crop, while in Cambridgeshire and Huntingdonshire Wheat, Barley and Oats are said to be good average crops; Turnips and Potatoes want rain, but Mangolds like the heat. Wheat is given as below the average in Norfolk, Barley failing for want of rain which is also much needed by Turnips and Potatoes. "No wheat straw," is the report from Suffolk, though the yield of grain may be fair. No disease among Potatoes so far and Barley good.

In Hampshire early sown Wheat on good land is quite an average crop, elsewhere below. Barley is ripening prematurely, and Oats would have preferred more moisture. Tares are very good; so far sheep in this county have paid well this year. Potatoes, a short crop and disease manifest. In Wiltshire the late sown Barley was caught by May frosts which the earlier escaped, and rain is wanted for roots. The good Turnip crops need rain in Bedfordshire, and Barley is coming on too fast. Wheat is said not to be filling well in Hertfordshire, and in Bucks it is thin and storm-broken in many places. In Oxfordshire Wheat and Barley are mostly under average, but better tidings come from Gloucestershire; and Somerset, which has much grass land, sends a grand record of hay.

Wheat varies from very good to very bad in Berks, but Peas have podded exceptionally well. Barley will disappoint the growers, and possibly the maltsters too. A sad record of crops comes from Essex, through destruction by hail, but early Potatoes have been good. In Surrey Wheat is said to be 10 and Barley 15 per cent. under average, but Cabbage has done well, notwithstanding the dryness. Hops are regarded as being 50 to 75 per cent. of an average in Kent; late frosts injured early Peas, and Turnips are suffering by drought. The majority of observers report Wheat as a poor crop in Sussex, Barley average, Oats short. Most Wheat is given as an average crop in Dorsetshire, and Potatoes look well. Reports are not very bright from Devon and Cornwall, except as to root crops, but in Monmouth all crops are said to be up to the average, except one or two lots of Oats, so Monmouth is to be congratulated.

WORK ON THE HOME FARM.

We are glad to hear of refreshing rains having visited many parts of the country; but, alas! all districts have not been favoured with them, and we know of several which are suffering from drought. The heat has not been so intense, but drying winds have prevailed, so that at the present time there is little or no moisture within 4 inches of the surface. The effect on Turnips and Potatoes is serious. Showers now would be of little avail; heavy and continuous rain is required both for roots and pastures. Grain crops, except Oats and late Barley, hold their own fairly well, and in the case of Wheat we can see an improvement, and an excellent prospect. Contrary to what one might have expected harvest is not approaching very quickly, except in the sunny south. We had rather it had come up to time generally, for the work amongst Turnips is so nearly complete that we should have been ready for it sooner. However, we must wait and begin as early as ordinary common sense will allow us.

Many pastures are looking like deserts; we have seen, in a good country, fields with nothing in them to hide a mouse, and the question of provision for our stock will soon be a serious one. We have a good store of excellent fodder put by for the winter; what will soon exercise our minds more will be how to keep the animals until that time comes without trenching on the winter store. What a contrast this all is to last season, when everything was growing fast and keep was almost too abundant. Streams are now running very low in the eastern and midland counties, and many ditches are dry or nearly so; an opportunity therefore offers itself for such being cleansed at a reasonable cost, and should not be neglected. Hedges, too, are now so well grown, and the wood so ripened that they might be trimmed pretty closely or even scotched without damage.

REMARKS.

25th.—Bright sunshine and fresh breeze; heavy showers at 2.45 and 4 P.M.
26th.—Bright and fresh morning; clouding over and a smart shower at noon; frequent thunder and occasional spots of rain from 3 P.M. and a heavy shower at 6.40 P.M.
27th.—Rain at 6.45 A.M. and at 11 A.M., and generally cloudy till noon; sunny afternoon.
28th.—Fair, but almost sunless, throughout.
29th.—Overcast day; a little faint sunshine after 3.30 P.M.
30th.—Overcast early; bright, warm, and fresh after 10 A.M.
31st.—Bright, with pleasant breeze.

Another brilliant week, with scarcely any rain.—G. J. SYMONS.

COLOURING GRAPES.

FEW things are more disappointing in Vine culture than badly coloured Grapes. Red Hamburghs are said to be as sweet, or even sweeter, than black, which is doubtful, and no one appears to care about setting the question at rest by means of analysis or even a saccharometer; but green Muscats are never so richly flavoured as those of a clear golden amber. There is something in colour, indeed, so much so, that scarcely any eater of Grapes cares about reds and grizzlies. Present-day Grapes are decidedly of two colours—the black and golden. Shades of these there may be, but the nearer the one to jet and the other to amber, the more the grower and consumer alike are satisfied.

Quality in Grapes, measured by whatever standard it may, must be accompanied by colour. Pale greenish, tinged and streaked with red or purple, berries of Black Hamburgh, fine as they may be individually and in the bunch, satisfy no one. Gros Colman, with a blue nose and a greenish shank end, annoy the grower and disappoint the eater. As for "green" white Grapes (so-called), they are dingy anomalies. Lack of colour is undoubtedly a great defect in Grapes, even beyond appearance, as such Grapes will not keep, and instead of getting sweeter they turn sourer.

It is worse than useless ignoring the fact that nothing gives so bad a character to Grapes as defective colour, and there are more ill-coloured Grapes now than there have been any time during the last fifty years. Why? There are often faults on both sides. More private gentlemen grow Grapes for market now than was ever the case before, and not unnaturally want a maximum of production—it may double the crop that was taken prior to the selling, and the cultivator is therefore impelled to make the most of his means, and, it is to be feared, is sometimes compelled to attempt impossibilities. Market growers crop the Vines from first to last within an inch of their lives, and they use tons of manure where the private grower and seller of fruit uses

hundredweights. The latter ought to know about these things, and not leave the grower to bear all the brunt of a collapse. The good grower of Grapes, who is properly equipped for the work, studies the Vines—brings his knowledge and experience to bear upon them, and the result is the measure of his matured judgment. Thus Grape growing is a question of ways and means—of skill and materials.

I find "muck" and "brains" are the chief factors with the grower of Grapes for market. The first saves watering, and the Vines receive no more water than is sufficient to make the nutrition soluble. Little of this runs away into the drains, the consequence of excessive drenchings of the border. Yet they have sufficient water, and not only is enough as good as a feast, but better. The Vines groan not under their burdens, because as the crop is so is the stamina supplied. The grower knows his Vines—studies them, understands them, and feeds them according to their work. The question of colour is one of nutrition from beginning to end—not of nutrition washed out of the border, but kept in it. Water and nitrogen may put on flesh, but not colour.

Vines require steady supplies of substantial nourishment. Potash, phosphorus, magnesia, and lime are the prime food essentials so far as colour is concerned, utilised by water and nitrogen. Build up the Vines from the start with phosphates, sulphates, chlorides, and nitrates in due proportions, and give no more water than is necessary for health, then colour will come, never by overmuch water. It is assimilated food that puts colour on Grapes. Let the Vines work from "morn to eve" pouring out water, manufacturing chlorophyll all the day long, and building up cells with strongly fortified mineralised walls. Air and sunshine, every leaf its share, will do the rest, and then having fed the Vines wisely, and cropped them judiciously, the best of colour will appear in the fruit.

The most foliage does not imply the best colour. It often means the reverse, as large flabby leaves, long-jointed, large-pithed wood are the precursors of loose bunches and ill finished Grapes. It is solidity in proportion to the weight of Grapes that insures both colour and quality, and firmness is due solely to the nature of the food and conditions of elaboration.

Overcropping results in indifferent finish. Some growers go so far as to make a point of colouring their Grapes by certain methods in ventilation at the time of ripening—good methods, no doubt, but the success that follows is mainly due to something else. Overburdened Vines may be helped in colouring, not by air alone, nor by drowning the roots, but by giving a top-dressing of Thomson's or other advertised fertiliser of proved efficiency, and, of course, it must be washed in for imbibition by the Vines, but to do this does not require an equivalent of 4 inches of rainfall where 1 inch is ample. The dressing often acts very well, the roots move, the laterals respond, and then more colour comes, though it may not be perfect, because, I am sorry to say, that Grapes wrong in colour cannot be so quickly put right. The elements of colour must be provided long before the berries change for ripening. An Apple to colour in the fruit room must be grown in the sun, not in the centre of the tree. Still, the dressing betters a wrong if it does not make it exactly right, besides the food given now is stored and helps the Vines at starting another year. Lightening heavily burdened Vines may do something towards those bunches left finishing better. It is very little, however, if the removals are delayed till the Grapes are advanced to the colouring stage. I have tried it on Gros Guillaume time after time. The effect was a delusion—just a case of the worst coloured bunches being cut off and the others looking better in consequence.

Then there is the matter of temperature. Some persons go so far as to credit dew with putting colour and bloom on fruit. It is the best thing I know to take it off. In an old book I find the moon credited with making grain golden. These oracles are beyond me; but I can get clearer, purer, golden tints into Muscat of Alexandria Grapes in July than under the finest harvest moon yet seen; so what acts on grain has no influence on Grapes. "Cold nights make Sloes blue" is a time-honoured belief, but not mine. Those grown in the shade will not turn blue, but those having sun all the summer will, if cut when changing colour, ripen off the tree. Still, heavily cropped Vines do colour better with a comparatively low night temperature than under a high one, turning almost black as Sloes outdoors in October.

Colour in Grapes, or in every other fruit, depends upon the means taken during growth to secure it. That is a due adjustment of the crop to the vigour of the Vine. Full exposure to light from the beginning of growth to the ripening of the fruit and foliage, due supplies of nourishment in available form right along from commencement to finish, and plenty of air with a comparatively drier atmosphere, appear to be the needful conditions at the ripening stage.

The whole question needs ventilation, for there are far too many Grapes defective in colour that cannot be regarded as overcrops, and it is just such cases that suggest the desirability of an exchange of views. There is the question of manures as affecting colour, some accelerating it and others doing the contrary. Then different varieties may need something variable in their treatment. These are interesting subjects, and could well be treated by experienced cultivators with advantage even to themselves, not to mention the rising generation, thirsting for information on the "queen of fruits," especially in the matter of colouring, for, without perfection therein the produce cannot be fully appreciated.—G. Abbey.

DEATH OF Mr. ALFRED SUTTON.

All who have had the pleasure of meeting Mr. Alfred Sutton must have been impressed by his urbanity, and will deeply regret to hear that he died at his residence, Greenlands, Reading, on Saturday morning last, at the ripe age of seventy-nine years. Mr. Sutton was for fifty years an active member of the firm of Sutton & Sons, but retired from the business, together with his brother, Mr. Martin Hope Sutton, the founder of the firm, who survives him, nine years ago, when the business was entirely made over to their sons, the present partners. He was more particularly interested in the floricultural part of the work, whilst his brother devoted himself principally to the agricultural and seed growing departments.

In his private life he took the deepest interest in all religious movements, especially those established for the benefit of young men. He was one of the founders and chief supporters of the Reading Church of England Y.M.C.A. He was a warm supporter of missionary work at home and abroad, especially the Church Missionary Society. At the present time three sons are working as medical missionaries in Quetta, Bagdad, and South Africa respectively. He built three mission rooms in populous parts of the town, also the coffee house known as the "British Workman." He was a Sunday school teacher and superintendent, and for some years a Churchwarden at St. John's Church. He took a great interest in education, and was a member of the School Board for fifteen years from its formation, when he was elected at the head of the poll. He was a staunch supporter of the Royal Berkshire Hospital, and for many years a member of the Board of Management.

Politically the deceased was a Conservative, but he took no active part in party politics. Mr. Sutton was a J.P. for Reading, and as a mark of respect to his memory, and to note the passing away of one of Reading's oldest and most honoured residents, the bell at the municipal church of St. Lawrence was tolled. A widow and ten children (seven sons and three daughters) survive him.

It can be said of Mr. Alfred Sutton that those who knew him the best esteemed him the most for his gentleness, uprightness, and kindly solicitude for the welfare of all who came within the sphere of his influence. His life has been a lesson of the most wholesome kind that cannot fail to have left its impress for good on the minds of many young men who have had the privilege of working under him during his long and honourable business career. The funeral took place yesterday (Wednesday).

Of the two brothers whose intelligence, energy and uprightness laid the foundations of the great house of Sutton & Sons of Reading, the

younger, Mr. Alfred Sutton, has just passed quietly and happily away. He was not so much before the public as his more active brother, Mr. Martin Hope Sutton ; he preferred the shade rather than the sunshine ; but his wise counsels, his gentle and loving disposition which endeared him to all with whom he came in contact, were of great value in the regulation of so great an establishment as that of the Reading firm. I had the privilege of knowing him for many years, and a man of a more gentle and equable temperament it would be indeed difficult to find. He was ever the same, and his time and counsels were ever at the disposal of those who needed them. He was a man of strong religious convictions and foremost in every philanthropic and religious work until age and infirmity compelled him to resign many of his engagements. I shall always retain a pleasant recollection of my intercourse with him in his own home, and should be sorry to lose the opportunity of testifying to the worth of a truly Christian man, and an honest and upright citizen. There are many, especially young men, to whom he has rendered great and valuable service, and who will ever cherish the most grateful recollections of the loveable man who counselled them as a father, and talked with them as a friend and brother.—D., *Deal*.

NOTES FROM IRELAND.

Our last brief notes from the Dublin district were chiefly concerned with anticipating the effects of the spring—"The spring made dreary by incessant rains," — and the consequent long-deferred work in its unavoidable hurry and rush. Although to balance up at present would be somewhat premature, it is, at least, interesting to note the rather important stage now arrived at, particularly in relation to the difficulties encountered at the start augmented by the abnormally wet winter which left the land in a highly saturated condition.

On the broader question of farming, which I venture to think is, possibly, better done on the whole in this my area of direct observation than in any part of the island, both present and prospective appearance are satisfactory. Late planting of the Potato crop undoubtedly entailed some anxiety respecting the effect that might obtain, but it is pleasant to record that those fears were groundless, and nothing could be finer in their way than the broad plantings to be met with on every side. The growth from planting time was apparently uninterrupted, and the sturdy luxuriant haulm has been for some time gay with blossom. Some acres near at hand of Sutton's Maincrop are really charming, giving the effect in the distance of an enormous Heliotrope bed at its best. Beauty of Bute, by contrast with the floral display made by the former, looks sombre, but the dark hued foliage is a picture of health.

Growers view present prices of earlier varieties now being lifted with something akin to dismay, as against the universal satisfaction felt by consumers who are now able to purchase the esculent tuber at the low rate of 2s. 8d. per cwt., city prices on the last day of July ; even previous to this a glutted market led to heavy cross-channel shipments. Improved varieties, imported seed, well worked land, and an energetic stirring and moulding as growth develops tell their own tale, and nowhere are disadvantages apparent as the result of late planting. On the contrary, where, in rare instances this season, undue haste hurried the seed into ill-prepared soddened land, weak gappy growth led to the conclusion that it was better to re-plough than chance results.

First and second crop meadows were converted into the hunter's provender with some little difficulty, owing to a spell of showery weather ; but the quality has not apparently suffered to any appreciable extent. Those who took advantage of a spell of splendid weather, with practically uninterrupted sunshine during the week ending July 17th, for the making up of hay on old pasture land were fortunate (or wise). From that date to the end of the month rain was more or less the dominant element. Some fine breadths of Wheat are here and there to be seen, and are now rapidly putting on the harvest tint. Turnips and Mangolds have from the start done well, and promise to make an equally good finish. To sum up this phase of culture, our neighbour the farmer may be congratulated on the general aspect—that is, if prices are left out of the question, which, we suppose, it is hardly possible to do ; but where so good a market is found between the city and its garrison on the one hand, and the great hunting centres of "The Wards," "Meaths," and "Kildares" on the other, demand will doubtless pay for supply—and pay well, for our hunting gentlemen know what is good, and, what is more to the point, insist upon having it. *Apropos* of this, the supply of home-grown wheat straw has for some time been exhausted, and compressed bales of foreign growth take its place. Grazing leaves the beast in that happy condition of not having to walk all day seeking what he may devour, for grass is both plentiful and good, particularly in those cases where a dressing of superphosphate was given, which appears to promote the growth of sweet herbage, particularly Clover.

Where farming merges into gardening in the way of vegetables for market (outdoor fruits, with the exception of Strawberries, are sparsely represented), the retentive soil of the Kildare side of County Dublin is admirably adapted for the production of good supplies of greenstuff, such as Brussels Sprouts, Broccoli, and Cabbage ; good samples of the latter, at various seasons, being shipped to Glasgow. Jerusalem Artichokes, also, are looked upon with favour, whilst Scarlet Runners and French Beans are well supplied to meet the demand of our own metropolis ; picking of the latter had commenced ere July was out. Field Peas have been, and are at present, both plentiful and good.

In Lord Annaly's demesne the extensive ranges of glass, chiefly employed in the production of Peaches and Tomatoes, excellent examples of each are to be seen. Of the former it would hardly be possible to find trees more luxuriantly healthy or carrying heavier crops of high-coloured fruit, and the Luttrellstown Peaches have created a name for themselves in the Dublin market, having their corresponding pecuniary value. With that popular production, the Tomato, Mr. Buggins, his Lordship's manager, is equally successful. In a general survey of hardy fruits the most optimistic pen-painter could show here but little *couleur de rose ;* bush fruits, to say the least, having been but thin in quantity and indifferent in quality. The same remarks will probably record the doings of the Apple and Pear tribe this year. A vagary recently noticed was a large wall tree of Louise Bonne showing quite a crop of bloom amongst the thinly dispersed half-swelled fruits.

It is gratifying to notice that among the arrangements for the forthcoming visit of the Duke and Duchess of York to our shores a visit to the Royal Horticultural Society's autumn show on the 19th proximo is contemplated. This will take place in Merrion Square, which from its general adaptability to the purpose is one of several moves in the right direction the Council have made to restore the prestige the premier society (so far as the prefix of "Royal" is concerned) formerly held.—K., *Dublin*.

WATERING WALL TREES.

An insufficient supply of moisture at the roots during critical times is the cause of many failures in fruit growing, especially in the case of trees trained to walls. As soon as the trees begin to suffer in this respect they become subject to the attacks of insects and diseases innumerable, which not only prevent the season's crop from finishing satisfactorily, but also weaken the trees to such an extent as jeopordise their prospect of producing good crops the following year. The present is a critical time, when the cultivator may, by a little extra attention, almost double the value of fruit grown upon walls. Inferior produce is often a drug in the market, but the finest samples will command remunerative prices.

Let us take, for example, Peaches and Nectarines which are beginning their last swelling. If given abundance of moisture at the roots, and a surface mulching of short manure, the fruit will attain a large size, and have good juicy flesh as well as high colour. Without extra moisture, small, dry, and often comparatively flavourless fruit will be the rule ; such can only be sold at rubbish prices, which scarcely pay for picking and sending to market. The same remarks apply to Pears ; fair examples pay, inferior ones do not. The Jersey growers, so long noted for their magnificent Pears, use enormous quantities of water throughout the summer ; to that fact, as well as to their fine climate, must be attributed their success.

To my mind, one of the first requisites for the profitable conduct of commercial gardening is an ample supply of water, with means of distributing it in an economical way. When it has to be carried or carted, the labour involved makes it too expensive for use on a large scale, and there are many instances in which a moderate outlay judiciously made will secure good water in abundance. Many gardens are so situated that streams on high ground might be easily diverted to properly made ponds or tanks, from which the whole garden could be supplied through pipes, no other power than the natural force of gravitation being needed to secure distribution. In others, hydraulic rams would force the water from lower ground into ponds or tanks, and thus supply abundance of tepid water. Rubber hose, with one of the many forms of distributors attached, could then be kept constantly going where needed, the only labour required would be that of occasionally shifting the distributor when a particular part had been thoroughly watered. Driblets are of little use in hot weather.

When abundance of water is given of course liberal feeding must be resorted to. This can be given in several ways—viz., by mulchings of manure, by applications of artificial fertilisers, and liquid manure given after clear water has been applied. When the

conveniences above described are not at command horse or hand watercarts must be brought into use, if fine fruit is expected, entailing many hours of laborious work. Many gardeners know well that this is one of the most difficult problems they have to deal with, yet they are obliged to struggle on attempting to produce good results under adverse circumstances, when a comparatively small outlay would soon repay the first cost.

In commerce this water question is one which receives just attention ; in private gardens it is too often neglected altogether to the great disadvantage of all concerned, especially in these days of rigid economy when gardens are expected to pay their way, which they never will do unless conducted on more intelligent lines. If their owners would grasp and grapple with this matter we should in the future see less waste of force and more satisfactory returns in gardens where the labour allowed is totally inadequate. Let us all, however, bear in mind, and act upon the stern fact, that at the present time wall trees carrying good crops must have water in abundance to produce good results.—H. D.

HARDY FLOWER NOTES.

Full of changes is the garden of hardy flowers. These come not as quickly as those of the kaleidoscope, but are, as it were, dissolving views melting imperceptibly one into another. From the time when the first Snowdrop pierces the winter-bound soil until the last Aster shrivels under the bitter frost-laden winds of the dying year the pageant of beauty moves along before our charmed eyes. Ere the Snowdrop's maidenly band has vanished from sight the brave Crocus comes into view, and before it again has passed away the Daffodils and Tulips draw near—a gallant band. And so it is as Summer dawns, reigns, and yields her sway to Autumn's golden rule.

The procession seems to come with richer and brighter beauty, bewildering in variety, clad in all the colours from the dye-house of Nature's laboratory. These summer flowers come in less formal bands than those of the earlier season. They are more mingled with others, yet look none the less beautiful because of this. The Gypsophila has for its comrade the Orange Lily or the Phlox, and neither suffers from the companionship—nay, rather each one gains, the lightness and grace of the Gypsophila showing well beside the stiffer beauty of the Lily or the rounded flowers of the Phlox, while they have their colouring softened and made more pleasing by the lace-like cloud cast over their glowing petals.

The rounded heads of some of the Alliums emerge from among their escort of Pinks ; Sidalceas, with delicate white or pinkish flowers, have their modest colouring made more pleasing by association with some deep crimson Poppies. The bright red or soft pink blooms of the Everlasting Peas climb up the trellis on the outhouse wall none the less happily because beside them are the bright orange-yellow flowers of that beautiful flower, the Eccremocarpus. And all this beauty, this pageantry, this gay colouring, soft grace, or elegance of form stand within the reach of almost all possessing a garden.

Those of us who care for rare flowers may indulge ourselves by acquiring plants, part of whose interest consists in their exceeding scarcity or in whose cultivation difficulties arise. Those who, from necessity or choice, prefer cheaper flowers or those needing the minimum of care can find among the hardy flowers many which are within their reach, and still as beautiful as those beyond their power. Among these will come the Madonna Lily, worthily so called, the flower of grace and purity, the flower with which is inseparably connected legends and traditions which make it doubly dear.

Even were it not so, and its only attraction its own intrinsic beauty, Lilium candidum would ever find its way into the affections of the lover of flowers, and occupy one of the best niches in his temple of beauty. It is not amiss to speak of it now when its pure flowers have just passed away, and it is time for those who have it not to think of procuring this Virgin Lily. August is, perhaps, the best time for planting, and no one should delay much longer in obtaining the bulbs. The question of where to plant is inseparably connected with that of the blight or disease which at times reduces to despair the hope of the gardener.

It would, perhaps, be rash to say that any precaution in this way would give immunity from an ailment so disappointing. That is too much to hope, as in some seasons there are gardens in which it appears to be impossible to ward it off. It is not, however, an impracticable thing to reduce to some extent the recurrence of the disfiguring blight which prevents the blooms from opening, and makes the beautiful Lily no longer a thing of joy. The facile pen of "D., *Deal*," has on page 71 dealt in a very useful way with the question of where to plant, and one is pleased to find it possible to be in full agreement with a writer of such long experience. This is all the more agreeable, because the frequent advice to plant in deep, heavy loam is not always satisfactory. One is not disposed to be dogmatical on the question—so varied are the peculiarities of gardens—but a sunny situation in light or sandy soil is what I should be disposed to recommend also.

There are some who advise planting in boggy ground, and others who are in favour of keeping the crown of the bulb above the level of the soil. The former I should hesitate to adopt for permanent planting, and the latter is not so satisfactory if regular and annual flowering is desired, as it is sure to be. It is better to keep the crowns at least 2 inches below the surface.

On the question of sun or shade, one may remark that comparison of plants in the same district appears to show positively that plants under the partial shade of trees are attacked in years in which those in full sun escape. Should the disease once appear there is little hope of much pleasure from the flowers that year. Anti-blight has, with some, enabled the flowers to open, even if the foliage had been attacked and destroyed. The absence of the leaves, however, detracts so much from the appearance of the plants that were it not that the application may be of advantage for another season it is hardly worth while to apply it. These remarks may be of service to some beginning the cultivation of this, the purest and among the noblest of all our hardy Lilies.

Among the hardiest of all our tall garden flowers are many of the Aconitums or Monkshoods. Their poisonous nature causes them to be shunned by many, and instances are said to be known of death having been caused by the roots being mistaken for those of esculent plants. This is a danger, perhaps, more apparent than real, and there are other flowers less valuable for garden purposes with equally dangerous properties. The beauty of the Monkshoods is sufficiently evident, and, if kept away from the vegetable garden and no pieces of root left lying about, any mishaps which might arise from their being mistaken for those of the Horseradish will be avoided.

There are many species and varieties, blue, yellow, and white being the prevailing colours. Of the many only one can be noticed at present. This is A. variegatum bicolor, a pretty plant with blue and white flowers, which always looks well when in good condition, and lasts long in bloom. The typical A. variegatum is said to be blue, and there is also a white form, but the one under notice I consider the brightest and most appreciated. The height to which it grows varies with the soil and other conditions, and may be stated generally as from 2 to 6 feet. Large, well grown plants are very effective with their neat leaves and rather loose racemes of pretty helmet-shaped flowers. Like most of the genus to which it belongs, A. v. bicolor is not fastidious as to soil or situation, and gives little trouble from year to year. Another satisfactory plant is the white variety of the black-rooted Mullein, which has the paradoxical name of Verbascum nigrum album.

Unlike many of the Mulleins, it is a true perennial plant, and is, moreover, perfectly hardy and easy to grow. Almost all who see it are pleased with its long spikes densely crowded with white flowers and contrasting purple centres. It is not a rare plant, although often absent from gardens, and even from many hardy plant nurseries. V. n. album is readily increased by division, and increases at a moderately rapid rate. In light soil it grows about 3 feet high, or a little more. The plants named are not such as will appeal to the owner of a large collection. They are cheap flowers, easily grown as a rule, and such as the beginner might well include in his garden.

We have all been beginners once, and in the days when our plants were few and our knowledge still more scant, we welcomed anything which would tell of such flowers as these. If these words bring some into the ranks of hardy plant growers, or help others on their way, they have served their purpose and fulfilled their aim. Those who wish to read of less-known flowers can have their innings again.—S. Arnott.

Fruit and Health.—Each year people grow to appreciate more fully the value of fruit, and eat it, not as a luxury, but as a staple article of food. Fruits are nourishing, refreshing, appetising, and purifying, and consequently have effect upon the health. Yet there are differences. Grapes and Apples are highly nutritious. Grapes usually agree with the most delicate persons, for they are so easily digested. Nothing is easier to digest than a baked Apple, taken either with or without cream. Oranges, Lemons, and Limes are of great value as a means of improving the complexion, and they are especially good if taken before breakfast. Ripe Peaches are easy of digestion and are sustaining. Nothing is better to enrich the blood than Strawberries, which contain a larger percentage of iron than any other fruit. Fruit with firm flesh, like Apples, Cherries, or Plums, should be thoroughly masticated, otherwise it is difficult to digest. The skin of raw fruit should never be eaten. Never swallow Grape stones. Stale fruit and unripe fruit should never be eaten, and very acid fruit should not be taken with farinaceous foods unless the person has vigorous digestion.

PROGRESS IN STREPTOCARPUS.

THE advance in many plants that have come under skilful manipulations of the hybridist is nothing short of remarkable. Notes might be written on the progress of Begonias, Carnations, Chrysanthemums, Pelargoniums, and many others, including the Streptocarpus, to which this article will be confined. The improvement that has been made with this plant is no less pronounced than in the case of either of those that have been named, and it has been effected during a comparatively recent period—indeed, it may be said to have taken place within the past ten years.

An account of the history of the Streptocarpus is given in the "Flower Growers' Guide" (published by Messrs. J. S. Virtue and Co., Ltd.), which we extract, together with some cultural directions which are there given.

"Let us trace briefly the genealogy of such flowers as those figured. About the year 1887 Mr. William Watson, the able assistant curator of the Royal Gardens, Kew, exhibited two new varieties of Streptocarpus before the Floral Committee of the Royal Horticultural Society. They were named S. kewensis (mauve purple with brownish stripes), and S. Watsoni (rosy purple), and justly awarded certificates. How were they obtained? S. Rexi (blue), introduced from South Africa in 1824, was crossed with S. Dunni (rose), Transvaal, 1884. This cross brought S. kewensis, which in turn, crossed with the Cape species S. parviflora (purple, white, and yellow), brought S. Watsoni.

"It may be presumed that even Mr. Watson could scarcely have foreseen that his two little floral children would so soon bring in their train the marvellously diversified and beautiful varieties now so easily obtainable from seed. The progress was brought about in this way:—

"About two years after S. kewensis and S. Watsoni were raised they attracted the attention of Mr. John Heal, one of the expert hybridisers in the establishment of Messrs. J. Veitch and Sons, Chelsea, who saw them planted out round the border of the large succulent house at Kew and flowering very freely. The Kew authorities gave Mr. Heal a few plants to see if he could make any improvement with them, as Kew is not a hybridising establishment on a large scale.

"No doubt the Kew people did well, as time has proved, to let others do their best. The result has exceeded the expectations of everyone who takes an interest in these beautiful flowers. The collection exhibited by the Messrs. Veitch in the Diamond Jubilee year at the show of the Royal Horticultural Society in the Temple Gardens, London, incited expressions of admiration and surprise. Among the exhibits were splendidly floriferous plants of what must in justice be called Veitch's Hybrid Strain, arranged in distinct colours to show how true each colour will be reproduced in seedling plants as the result of careful fertilisation. There were pure whites without any trace of colouring, then white with dark blotches, magentas with rich and distinct shades, violet, purple, rose, pink, and various tints practically indescribable. Three varieties are shown in the woodcut (fig. 20).

"Exhibited at the same time were three other distinct strains which demand attention. The first, known as S. gratus, is very distinct. The flower stems, from 6 to 9 inches high, are very strong and freely produced, some of them bearing from twenty to seventy flowers and buds, which means a continuation of bloom for several months. The flowers are about an inch across, and the colours bright and showy, including terra-cotta and rose shades. This strain, with its several varieties, was obtained by crossing the African species S. Dunni with Veitch's hybrids.

"The second strain which merits special notice was named Mrs. Heal, in commemoration of the late lamented wife of the raiser. Mrs. Heal is in truth a beautiful and distinct Streptocarpus, and no doubt the forerunner of a new section. The flower stalks range from 9 to 15 inches high, and terminate with six to twelve flowers of a rich violet blue shaded with purple, the throat having a yellow band with maroon spots on the lower petal, the flowers being 1½ inch in diameter. It is the result of a cross between S. Wendlandi and one of Veitch's hybrids. The plant is of good habit and floriferous with several leaves, unlike S. Wendlandi, which is remarkable for producing only one huge leaf and very tall spikes of blue flowers.

"The third strain, S. pulchellus, is perfectly distinct from the others. It is light and graceful both in growth and flower. The plant is compact, and the long tubular flowers are borne on erect stems from 12 to 15 inches high, with twelve to twenty on each stem, in the most delicate lavender tints. Where light and graceful flowers are in demand, this strain will supply them. It was obtained by inter-crossing S. Fannini and Veitch's hybrids.

"A new strain was exhibited at a meeting of the Royal Horticultural Society in May, 1897, which received an award of merit. It is a charming variety, called S. achimeneflora from the resemblance of the blooms to some of the small-flowered Achimenes. The colour is soft blue, with clear yellowish eye, and the habit graceful. It was obtained by crossing S. polyantha with Veitch's hybrids.

"Other firms are improving the Streptocarpus, and no one can foresee what the results will be, but already the plants under notice rank among the most useful for the decoration of the conservatory, greenhouse, or drawing-room during the summer months, especially when grown like those exhibited at the Royal Horticultural Society in 1896 by Mr. Beckett, of Aldenham House Gardens, Elstree, each bearing from twenty to thirty stems, with four to six flowers on a stem.

"Not only will varieties of the Streptocarpus be grown in large gardens, but they are equally suitable for the amateur with his small greenhouse, in which the plants may be had in flower from April to October, as fresh stems are produced if the old ones are removed when the flowers fade. Moreover, the plants will be quite safe in the winter in a temperature ranging between 38° and 45°; but they do not require water at that season till the soil gets dry enough to crumble freely when rubbed with the finger; then sufficient ought to be given to pass to the drainage, not a drop being poured on the foliage or in the centre of the plants, but only on the soil. Damp is the enemy of the plants in winter, and if any decaying parts appear they must be promptly removed. Streptocarpus will grow and flower well in cottage windows where they receive plenty of light, as they do not object to a dry atmosphere. They are best kept cool in summer, must never be overpotted, nor must the soil be allowed to become dry when the plants are flowering, while they enjoy shade from the sun

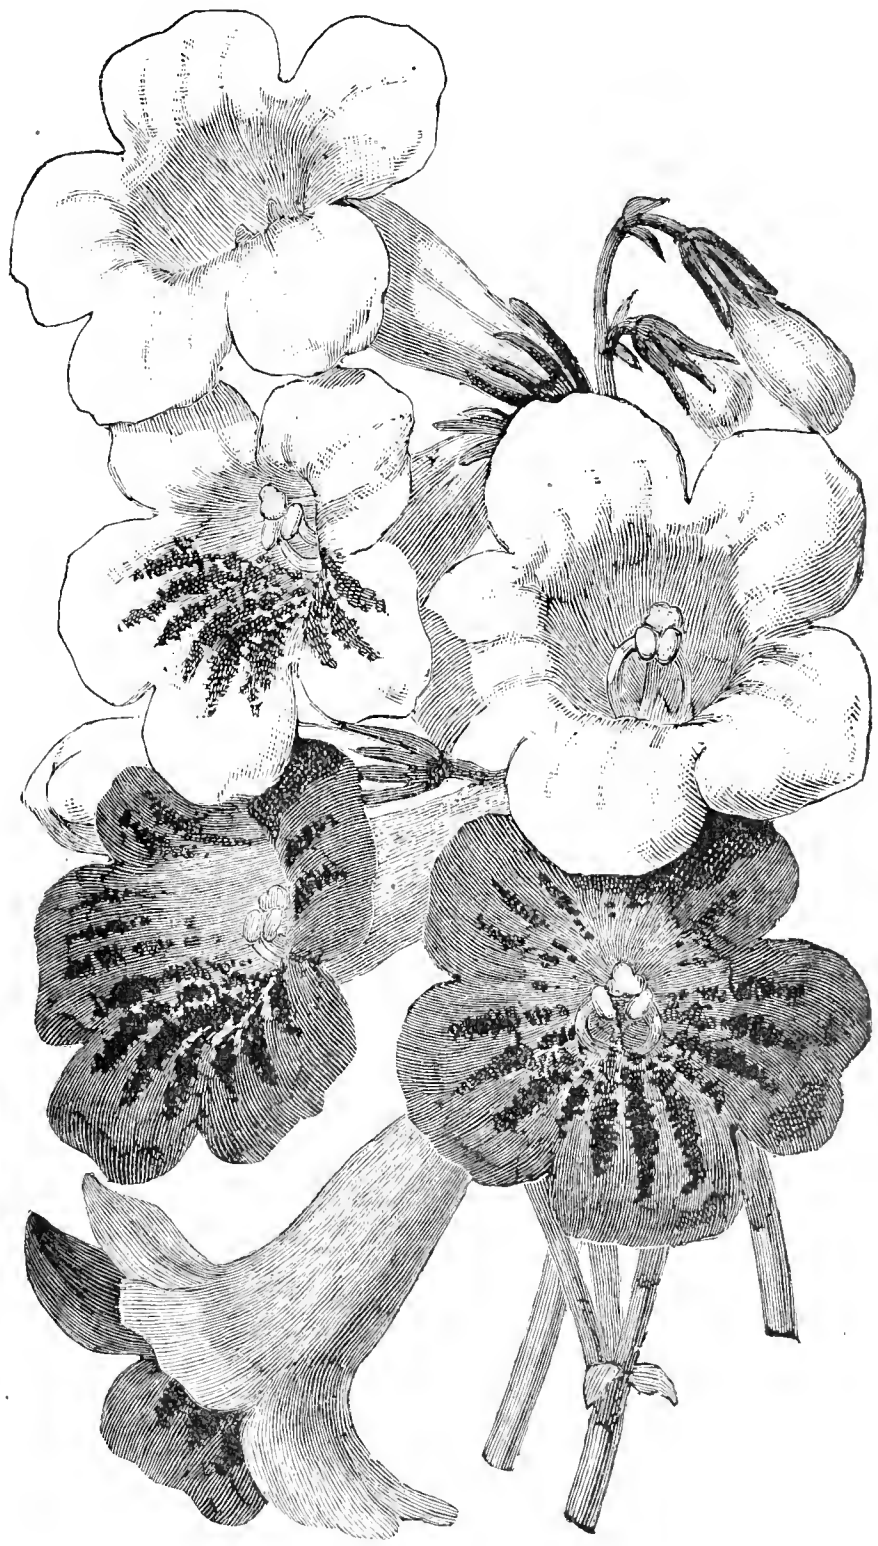

FIG. 20.—HYBRID STREPTOCARPUS.

as its rays become powerful, these having a tendency to scorch the leaves, especially if the plants are dry at the roots. With proper care they will flower well for three or four years, each year becoming stronger under good culture, throwing up flower stems continuously.

"As before stated, any desired number of plants may be raised from seed, from which new varieties will be forthcoming. Streptocarpus seed is very fine and requires special attention in sowing. Drain the pots well, and three parts fill with a mixture of turfy loam, leaf mould, and sand, which make moderately firm. Then add half as much of the mixture finely sifted and make it perfectly smooth. If in the least dry, give a good watering through a fine-rosed can, and three or four hours afterwards scatter the seeds evenly over the surface and press them gently down, not covering with soil. Lay a square of glass over the pot, tilt it up a little, and shade during the day with thick paper to keep the light and sun from the seed. Place the pot in a temperature about 65°, away from draughts, and examine it carefully every morning and evening to see that the soil does not get dry, because there the secret rests in insuring growth; if the soil and seeds are allowed to become dry once the endeavour to raise plants will prove a failure.

"The seedlings grow very slowly at first. When large enough prick them off singly and give them a little warmth. Plants raised from seeds sown in December, January, or February will give several flowers the same year, commencing from July to September. The following spring the plants become stronger and flower freely. Repot in February or March in a mixture of about two-thirds turfy loam, one-third leaf mould or peat, with silver sand added. The Streptocarpus can be increased by division, also by cutting the leaves like the Gloxinia.

"Few, if any, flowers during recent years have made the same progress in public favour in so short a time as have those under notice, and it may be expected that they have a great future before them."

HARMFUL AND HARMLESS GARDEN MOTHS—6.

MANY of the moths that appear about gardens have been bred upon the hedges that enclose them, or that are in the vicinity, and especially upon those of Hawthorn or White Thorn, which of all deciduous shrubs is still most popular for this purpose. Privet, however, is a successful rival, and it has the advantage of being less infested with caterpillars than is the Hawthorn; also, it remains green through the average British winter. We have to thank the Flemings for the re-introduction to our island of quick or living hedges, since those formed by Saxons and Normans to protect gardens or fields were made of dry boughs stuck in the earth. The Romans, it is true, knew how to plant green hedges, but this art, like others, was forgotten after they ceased to govern Britain.

Probably one reason why Hawthorn became a favourite for hedges was its readiness in producing side shoots; certainly as a guard it cannot rival the denser Yew and the spiny Holly. We have heard a remark made to the disadvantage of Hawthorn, that this shrub is the customary food of many caterpillars, therefore they might travel from it to fruit trees, Roses, or other garden plants near. But, on the other side, it may be said that Hawthorn hedges, being attractive, draw insects to them which would, if they were absent, interfere with the produce of our gardens and orchards. And this prologue brings us to a couple of moths, akin to the tiger race, that have an interesting history, unfortunately rather tangled by some confusion of both the English and Latin names, which has made it difficult at times to know which of the species was meant by describers. Then the question of correctly determining a shade of colour has to do with it, for at a hasty glance gold and a golden brown may be mistaken in a moth's tail.

Now, about July we are likely to see, resting on a tree or wall, perhaps crawling along a twig, a middle-sized moth, garbed in white with a body somewhat stout, and darker at the tail, the antennæ feathered. This might be the brown-tail, but most probably it will be the gold-tail, or Liparis auriflua, an insect not harmful except as a feeder upon Hawthorn while a caterpillar. This I have had brought me by gardeners as a curiosity; it is usually full-grown in June, and is certainly handsome. It is both hairy and tubercled, having also two cup-shaped marks upon the back, from which some supposed the creature could eject an acrid fluid; this appears to be a mistake. Observations tend to prove that the irritant to the skins of some persons is the hair of the caterpillar, thrown off at moulting, also in small portions at other times; the same effect is noticed in the kindred species. The colours are a conspicuous scarlet and white upon a ground colour of black. Hatched during autumn, the young gold-tail feeds a little then, but soon spins a small cocoon, in which it sleeps solitary until the buds open in spring. The species is distributed all over Britain, more abundant some years than others; the caterpillar is, for obvious reasons, unattractive to birds.

The brown-tail (Liparis chrysorrhæa), which has often had, by mistake, the name of the preceding given to it, is, now at least, a local species with us, though in a small range of ground it may be very plentiful. Its distinction is chiefly, as above stated, in the colour of the tail; also, this moth is inclined to be, I think, a trifle larger than its relative. Nor is the caterpillar notably different, even to the eye of an entomologist. In habit, however, they do not resemble each other, for all through their life the brown-tail caterpillars are sociable, as parties of various numbers construct each a common chamber of silk, into which they retire at night or during bad weather. When winter comes this abode is strengthened against the cold, and the entrance closed up till spring by the caterpillars. The early summer is their season for eating most voraciously. I have no doubt that the insect is still injurious to fruit trees in France, Germany, and other parts of the Continent, and was formerly so in Britain, occasionally, at least; one of its special years is recorded—viz, 1782, a pamphlet describing the mischief done then being published by Mr. Curtis. Great alarm was caused throughout the country that summer owing to the sudden profusion of brown-tail caterpillars, and the attacks they made upon many shrubs and trees, fruit trees suffering greatly, as in Middlesex and Surrey.

Some attempts at their destruction were partially successful; anyhow, the species was not particularly noticeable the next or following years. Fortunately, it is the victim of an ichneumon fly, which places its eggs upon the caterpillars in spite of their hairs. It may be added here that this moth, and the gold-tail too, cover their eggs with a layer of down, though they are laid in July, a circumstance certainly curious, about which there has been a lively discussion, on which I need not enter. At present, these caterpillars are seldom found in Britain except on hedges of Hawthorn and Sloe; but it is advisable for fruit growers to watch them where they appear.

I may be pardoned in introducing a little bit of local history which is *apropos* to my subject. On a winter's day, some fifteen years ago, walking on the old Dover Road near Gravesend, my attention was called to the unusual aspect of a hedge. Upon examination I discovered it was thickly dotted over with the nests of the brown-tail moth. Further researches showed many more on other hedges between that town and the village of Chalk. The following spring and summer, as the caterpillars were plentiful, and much fruit is grown in the district, I called the attention of farmers and gardeners to a possible danger; but no steps were taken. Probably the caterpillars were not very likely to migrate; the moths, however, might easily have flown over to the adjacent orchards and laid their batches of eggs.

A large number of caterpillars fed up the next summer, producing a host of moths and a big brood of autumn caterpillars, so that in the following winter the nests were still more plentiful. Upon one smallish shrub I reckoned thirty nests, which, at the moderate average of fifty caterpillars to a nest, would make 1500 there waiting for action next year. And later the hedges did suffer severely. The omnivorous character of the species, if need be, was shown upon a mixed hedge where every shrub was stripped, even the Elder, not a favourite with caterpillars, being defoliated. Yet still the caterpillars kept to the hedges and some scattered Elm trees; but it seemed only a question of time as to their reaching the fruit trees, unless there was some check. Happily Nature did what man left unattempted—a rainy winter, with stormy winds, killed a large proportion, assisted perhaps by parasitic foes, and another summer but few caterpillars were abroad. Afterwards the insects, so far as I know, have vanished from the locality altogether.

The satin moth (Liparis Salicis) might be mistaken for one of the preceding; it is all white too, but has a silvery gloss upon the wings. Its presence in gardens is accounted for by the occurrence of the caterpillars upon different species of Poplar; they are conspicuous by their spots of white and red, slightly hairy too, but are seldom numerous enough to disfigure trees or shrubs. Also I have seen, even in a London garden, the pretty caterpillar called the "hop-dog" by some authors, though I never heard that name applied to it in the Kentish Hop districts, and from observation can testify it does not often feed upon that valuable plant, its diet being somewhat miscellaneous. Certainly a handsome caterpillar, the green ground colour marked with slashes of deep black, and adorned by pencils or "tussocks" of yellow hairs. In habit the grey moth (Orgyia pudibunda) is somewhat retired, and flies little even at night.

Quite a contrast is its lively small relative, O. antiqua, also called the vapourer moth from its peculiar undulating flight. One that may be seen even in the busy streets of a big city; the caterpillar

making itself at home in any garden, large or small. Sometimes it causes annoyance by feeding upon standard Roses, but it is a species easy to find and remove. Mr. Wood has pointed out that the vapourer might be a very troublesome insect to us if the fat-bodied wingless female were not often eaten by birds, and he thinks they also peck off the eggs placed upon the cocoons, which do not hatch till spring. Both moths and caterpillars are about during June, July, and August.—ENTOMOLOGIST.

CHARACTER SKETCHES.

BUSY MEN.

HE at the helm, ever ready to take advantage of all side winds to bring our craft nearer to the port of perfection, gives us under the above heading two studies in life—a gardener's life, and neither of them understudies either. Prompted by his kindly appreciative remarks, not less by sundry wholesome correctives administered at divers times by "hand," I venture upon the endeavour to express some thoughts he has piped up. So diverse are these studies that at first sight it may appear as if the lessons they convey amount to what may be termed negative and positive teaching. Yet upon reflection the dual subject may resolve itself, as I think it does, into one question; a question which has previously been placed before our young thinkers and workers—viz., adaptability to circumstances. In no other way can I see the course open to approach and free of some rocks that we would wish our young craftsmen to steer clear of.

For distinctive purposes we may style the writer of the first letter Mr. A., the second Mr. B, both exceedingly busy men as per statement of details, and apparently having but one kindred feeling—viz, the desire to abandon the implements of play and of labour for the pen. As they meet on common ground in these pages by the employment of their pens in the good cause, we may take it that neither the stern realities of labour as so graphically depicted on the one hand, nor the comparative frivolities (comparative only) of life on the other, can veil the regrets they equally feel at the temporary absorption of their powers; *ergo*, they are both gardeners—gardeners in the fullest sense of the word. How can we reconcile the diverse employment of that great energy undoubtedly displayed? How extract the moral from each phase of life and blend the apparently opposing elements into a stimulative mixture for "our boys?"

It would be needless to ask any young gardener worthy of the name what his chief end and aim of life is, and there is little doubt that he has models in his mind's eye of great men who have gone or contemporaneous men of mark. Such models, of course, include neither demon bowlers nor eminent batters, for our goal does not lay in their direction. The type as represented by Mr. B., and of whom one ventures to think from data afforded by his letter he is an example as perfect as it is possible to find, needs but brief analytical comment. For such men there is, and always will be, ample room in the world as long as that mechanical force is permeated to its lowest strata by the higher intelligence clearly presented in this case.

Possibly some young readers will jump to the conclusion that the labours as defined are mere drudgery, but a little observation of similar cases they may meet with will show the reverse. Nine out of ten, it will be found, point with pride to the hundreds or thousands of plants they have potted, planted, or propagated, and anticipate with pleasure the results of sound workmanship. We take little heed of anything in the shape of a grumble, should such be forthcoming, that they have no time for recreation whether as essay writers or what not. The grumble is a privilege few care to be deprived of, and any commiseration shown by sympathetic friends will at once prove itself to be superfluous. This, at a rough estimate, is the case with nine out of ten. Of the tenth, it will be found that labour has been unsweetened by those compensating influences, hence it is regarded as pure drudgery by one who has mistaken his vocation in life.

A nobleman's gardener with whom I was well acquainted provides a character sketch similar perhaps to that suggested by Mr. A's letter, illustrating, as it may appear to do (appearances are so often deceptive) the lighter side of life. Probably our boys will think it much the nicer type—the pleasantest kind of a gardener's life. I do not think my friend thought so, but tact prompted him to cheerfully acquiesce with the young heir's wishes that he and his young men should take an active part both in a cricket and football club he had organised among the employés on the estate. And, really, these young athletes when discarding the blue apron and donning the monogram-embroidered jerseys were with their chief a credit to the team. They played heartily when they played and worked as heartily when they worked, owing, I think, to my friend's common sense and adaptability to a variety of circumstances which in some shape or form, though seldom similar to this, perhaps, enter into most men's lives.

One thing remains to be impressed—viz., that he, the head gardener, was eminently qualified to hold his highly responsible position as such, for, with the peeling off of that companionable garment, the jersey, he at once put on his firm and dignified demeanour, which entailed the unqualified respect of his subordinates. Other types crop up in memory which would needlessly prolong this paper, for though, as character sketches, they are, at least, interesting, and capable of being made profitable to boot, the youngest observer is privileged to extract the morals from them himself; and I venture to add that the best method of doing so is to note all the good points of others for personal benefit, and to endeavour to gain that great gift of seeing ourselves as others see us. I am sure our young students will have ample hard work, as depicted in Mr. B.'s letter; they may, or may not, be busy in the manner exemplified in Mr. A.'s, but they may turn all to advantage by studying all types, for "The proper study of mankind is man."—AN OLD BOY.

ANTHRACNOSE OF MELONS.

I HAVE read "The Young Gardeners' Domain" columns of the *Journal of Horticulture* with considerable interest, and especially the articles on Melons, noting, in the issue of July 29th, page 106, reference to "enemies," "disease," and "anthracnose" by "Elveden," who couples my name with the latter disease, and a request for information in respect of a remedy.

Allow me to compliment "Elveden" on his singularly accurate and carefully recorded diagnosis of the malady known as anthracnose—a word with a meaning, no doubt, on the continent of Europe and in America, but I cannot make anything of it in plain English but "rot." It does not appear to affect Melons in the United States, though the cultivators in some parts only know "bitter rot," "ripe rot," or "Apple rot" too well, as it is, according to Prof. H. Garman, "no uncommon thing for three-fourths of all the fruit on a tree to be rendered worthless by its attacks." I mention this, as "Elveden" simply alludes to the disease as anthracnose, and the fungus causing it as Gloeosporium. What species? Melons first went wrong with me in 1873, Colston Basset being the variety, and Moreton Hall, a red-fleshed, would not take on the fungus.

The fungus causing "bitter rot" in Melons will spread from them on fruit-room shelves to either Pears or Apples that may be in the same structure, but only soft-fleshed varieties of these are affected, the fruits rapidly becoming brown, and little black pustules appear on the skin. These are not often seen on Melons, for the fruits ferment and swarm with "bacteria" (Bacterium termo), thus making end of the fungus, but when any pustules come on the skins of Melons they are identical with those found on the Apples.

On Melons the disease may commence from a spot almost invariably on the under side of the fruit, and not far from the apex. It spreads somewhat after the manner of canker, and is more or less arrested by quicklime. Still, as the mycelium acts internally, the fruit sooner or later rots inside, and the fungus alone is responsible for the nauseous flavour of the fruit. In such case we may get the small black pustules, or fruiting bodies of Gloeosporium fructigenum. These are produced in a receptacle, and bear the spores on threads springing from the aggregated cells. They are not resting spores, but the early form of some other fungus.

The Melon affected may give a salmon-coloured spot; then we have fruit-spot fungus (Gloeosporium laeticolor), common enough on Grapes, Peaches, and Figs, and which pushes its minute spores from the pustules at the tips of threads, which appear like tendrils. These minute spores are oval, but soon become round in a rather dry atmosphere, and may live over the winter. That is the only tangible explanation of the disease being carried over from year to year on Vines or anything else, and washing the rods in winter with a solution of sulphate of iron is a preventive.

Melons are at times so grown as to favour the development of the fungus, for it may affect them one year, likewise Apples and Pears, and not appear again for years. As the spores survive in a Melon house it follows that thorough cleanliness is a prime factor in banishing the enemy. The next thing is not to allow water to remain on the fruit for any length of time. Then, the atmosphere being buoyant, I do not consider there will be any anthracnose. It is damp and a somewhat low temperature that gives the fungus its chance.

As a preventive of attack I have found dusting the plants with a powder formed of equal parts of best chalk lime, air slaked, and flowers of sulphur after the Melons are half swelled, the best. Before they are half to three-quarters swelled the fungus does not appear on them, and as spider comes about the same time the fumes given off by the sulphur act well against it.

As regards remedy, when the fruits are attacked there can be none, as the mycelium of the fungus strikes too deep for anything to reach it. What little flesh remains sound after an attack is the most enduring in the taste of anything I know of in fruits. Burn infested fruits, and practise thorough cleanliness, with high-class culture. If these jottings be of any use to "Elveden," the labour will not have been in vain.—G. ABBEY.

Stockport Autumn Show.

Five dozen classes find a place in the schedule of Stockport and District Chrysanthemum Society's tenth annual Show, which is to be held in the Volunteer Armoury, Stockport, on November 19th and 20th. Good prizes are offered in many of the classes, including a silver cup, in addition to the first prize for a group of Chrysanthemums, and another one for twenty-four cut blooms. Each cup has to be won twice before becoming the absolute property of an exhibitor. Besides Chrysanthemums, fruits and vegetables find a place, as well as a section that is confined to cottagers. The Hon. Secretary is Mr. R. Hollister, 29, Little Underbank, Stockport.

Wolverhampton Chrysanthemum Show.

We have received the schedule of the exhibition which is to open on November 3rd. It is a voluminous affair, and time and patience seem to be needed for finding the classes, which are inserted here and there among advertisements of bread, boots, bedsteads, blankets, cartridges, and other requisites of Chrysanthemum growers. We observe that £4 are provided in each of two classes for twenty-four incurved and twenty-four Japanese blooms, three other good prizes following in each. This provision should bring good competition. The same amounts are offered for groups of Chrysanthemums, which are to be judged by points from ten as a maximum for Japanese, eight for incurved, eight for Anemones, six for variety, six for dwarfness, and ten for general effect. This decision of the Committee is introduced by a little homily or explanatory essay. We should have thought it clear enough without, as affording guidance for exhibitors and judges of a commendably definite character.

Paris Chrysanthemum Committee.

Four numbers of the Journal of this Committee have now been issued. No. 3, although published early in the year, has, with No. 4, only recently come to hand, and a brief mention of its contents may be interesting. It contains a list of all the classes and prizewinners at the show in November last, together with certificates awarded at the various meetings of the Committee on September 23rd, October 22nd, November 12th and 17th. A report by Mr. Fatzer on new varieties exhibited at the show, a report on Chrysanthemums and other ornamental plants at the same show, a report by Mr. Nonen on Mr. Calvat's collection at Grenoble, a report by Mr. Rosette on Mr. de Reydellet's collection at Valence, and concludes with a list of members of the Committee, some seventy-three in all. Part 4 contains the rules and regulations, and also the schedule for the show to be held in the Tuileries Gardens next November; an article on the work of the Committee during the year 1896, written by M. Lemaire; an article on "Progress in the Cultivation of Chrysanthemums," by Mr. Yvon, and other matter.

I notice that a certificate has been awarded to a sport from Viviand Morel, described as of a pale yellow colour tinted old rose. The name given to this sport is J. B. Yvon, but judging only from the verbal description there would seem to be some resemblance to the well-known English sport from the same parent, Charles Davis.—C. H. P.

FRUIT SHIPMENTS FROM COLORADO.

I have more than once during the past few years furnished your paper with horticultural items from Colorado. It will interest your readers to know that the fruit crop of all kinds this year is estimated by the Secretary of the State Board of Horticulture at over one million pounds (£1,000,000) sterling, considerably more than half of which money will be realised from markets outside the State. This is not a bad showing for a State which is usually regarded by people at a distance as producing little else but gold and silver, and where so recently as 1884 fruit growing was locally regarded very much in the light of a questionable and somewhat quixotic experiment. Some years ago Colorado commenced shipping Potatoes, on account of their superior quality, to populous centres over 1000 miles distant. Her next horticultural article of export, also on account of its superior quality, was Celery, which was sent in considerable quantities—*i.e.*, in car load lots, to such distant points as Galveston, New Orleans, Kansas City, Pittsburg, Chicago, Detroit, and other destinations.

In April last four car loads, representing over 40 tons, of Ben Davis Apples, grown in a 90 acre orchard within a few miles of Denver, and kept in cool storage, were shipped to San Francisco, on account of their quality. Practical experience shows that Colorado grown Apples, owing to altitude and climate, survive cold storage better than those grown under more tropical conditions.

During the last dozen years at least 100,000 acres of orchards have been planted in Colorado, and this year sees not only the "bearing" acreage much increased, but an abnormally heavy crop, particularly of Peaches, simultaneously with partial Peach crops in the Eastern States of Delaware and Maryland, and also in Michigan. The fruit growers of different sections of Colorado are organised into effective associations, have arranged for agents in Chicago and other eastern cities, and the railroads are co-operating with favourable rates to get the fruit to distant markets.

Mesa County, on the Pacific slope of Colorado, has 40,000 acres of orchards, ranging in size from 10 acres to 160 acres, and upwards, of which 12,000 acres are bearing. It is expected that from the vicinity of Grand Junction alone there will be shipped this season 600 cars of Peaches, 50 cars of Pears, and a large quantity of Prunes, Plums, Apples, Grapes, and Apricots. When your readers remember that the American railroad car is twice the size of the English railroad car, some idea will be gained of the extent of the fruit shipments from this one locality. It is estimated that the fruit growers of Mesa County alone will this year net about £80,000, after payment of railroad freight, commissions, and other incidental charges.

Delta County, also on the Pacific slope, has 2000 acres of bearing trees, and will ship a proportionate quantity of Peaches, Pears, and other kinds. This county is sending Peaches to California on account of their superior quality. Montrose County, also on the Pacific slope, will equal the production of Delta County. The above three counties will this season produce about 3000 cars of fruit, much of which will be shipped as far east as New York, Boston, Philadelphia, Baltimore, and intermediate cities. On the Atlantic slope of Colorado, Fremont County takes the lead as a fruit producer, excluding Peaches, having 5000 acres in fruit, mostly surrounding Cañon City. This county alone will this year ship to other points 25,000 barrels of Apples, and for six weeks recently shipped 1000 crates of Strawberries per day. Boulder, Arapahoe, Larimer, Otero, and other counties on the Atlantic slope of Colorado also have large Apple orchards, and it is estimated that the Apple crop of the whole State this year will reach 300,000 barrels. There are a number of Englishmen among the horticulturists of Colorado.—Thomas Tonge.

CARNATIONS AT BOWDEN HILL.

The season, judging from reports which have appeared of late, and from personal observations, would seem to have been peculiarly favourable to border Carnations, for almost everywhere they have been abundant both from seeds, cuttings, and layers. No doubt the mildness of the winter contributed somewhat to this wealth, for casualties, which in some winters are so numerous, were extremely few in the last, and diseases are much less rife than usual.

Although I have seen Carnations doing well in many gardens this season, I have found none to equal those now almost over in Mr. Harris' garden at Bowden Hill House, Chippenham, the plants here being extremely vigorous, free flowering, and quite exempt from spot. Some 3000 plants occupy the borders in the kitchen garden, in many varieties, all grown from layers or cuttings, and the quality of the individual blooms and the collective display is creditable in the highest degree to Mr. Penton, Mr. Harris' able gardener.

There are 200 each of the old Crimson Clove and Germania, which must have made a good show in themselves, the former producing as many as fifty to sixty blooms, and the latter thirty flowers, on a plant. Maggie Laurie and Gloire de Nancy have been almost equal to those already named. Mr. Penton has found in Pasha a rival to the well known favourite Mrs. Reynolds Hole. Its colour is brighter, and the pods are exempt from the failing so common to many otherwise good Carnations—bursting. The Pasha must become a favourite, as Mrs. R. Hole has been for so long. Grandiflora is another very beautiful one, white with bright pink narrow stripes. Rose Celestial is a very bright flower; and Napoleon III. is a deep red. Duchess of Orleans, a slightly paler flower than Germania, possesses a delicate scent which does not belong to many yellow forms.

A few among other good varieties include Sir H. Calcraft, Mrs. R. Sydenham, Queen of the Bedders, G. H. Sage, The Countess, Jersey Maid, Ketton Rose, Alice Ayres, Agnes Chambers, Dr. Parker, Montague, Lord Byron, and Niphetos. In a large collection there are sure to be many that do not come up to the standard of any individual grower, and the process of weeding out such, and the introduction of newer ones take place annually. Only the best are retained at Bowden Hill even from among named varieties, than which no others are grown.

From seed, however, it is an easy matter to get a good selection, and a great wealth of variety is obtainable from seedsmen who make Carnations a speciality; and where house decoration is carried out on a large scale, the single varieties cut with long spikes are sometimes appreciated as much as double blooms, especially for tall vases. Very effective arrangements may be made from single flowers, and the seedling plants have the merit of producing material for cutting in quantity. From seed they are not much trouble, because they may be finally planted direct from the seed boxes, and when established early they are very hardy, more so, in fact, than layered plants. Mr. Penton finds a mulching of short grass from the lawn mower a good preservative of moisture about his plants, and it appears to suit Carnations splendidly.

In addition to the border plants, a goodly number (500) are grown in pots, to precede the outdoor stock, including 150 Uriah Pike. Beside these, 200 of the winter flowering section are cultivated in 48-sized pots, included among them being such as Miss Joliffe, Mdlle. Thérèse Franco, Mrs. L. de Rothschild, Mrs. Moore, Madame Carl, and Winter Cheer. From these remarks it will be observed that Carnations are a speciality at Bowden Hill, though other features, including Orchids, are by no means neglected, but very much in evidence; of these reference must be deferred until some future date.—W. S., *Wilts.*

Notes & Gleanings

EVENTS OF THE WEEK.—The great event of the forthcoming week is the Royal Commemorative Shrewsbury Floral Fête, which will open on Wednesday next. Magnificent as these exhibitions always are, it is anticipated that the one of 1897 will eclipse all others, as the executive has made extraordinary efforts to have something entirely out of the ordinary for the deputation from the Royal Horticultural Society to see. This deputation will, we believe, consist of Sir Trevor Lawrence, Bart., with Messrs. H. J. Veitch, T. Statter, S. Courtauld, P. Crowley, J. Douglas, H. Selfe Leonard, W. Crump, J. Smith, and the Rev. W. Wilks. On the same day as Shrewsbury there is to be a Jubilee fête at Boscombe, Bournemouth, which also promises to be good; but it is regretable that the dates are in conflict.

—— WEATHER IN LONDON.—The three days ending Saturday, August 7th, were intensely hot and most people found it impossible to keep cool. The temperature on two occasions reached upwards of 80° in the shade, the highest being 87° on Thursday last. Sunday was a thoroughly wet day, the rain coming down heavily almost throughout the day. As a result it was much cooler and pleasanter. Monday also was fairly cool, but Tuesday was again intensely hot, while on Wednesday it was dull and warm.

—— THE FORTHCOMING SHREWSBURY SHOW.—I notice by advt. in the Journal that the annual Show takes place on the 18th and 19th insts. Last year I had the pleasure of visiting the Show. Although I had to walk about twenty miles in the dusty roads I did not begrudge the day's outing. What struck me as a great drawback was the dusty state of the atmosphere in the principal tent where the dinner tables were laid out, and the coating of dust everything was carrying, and the fruit spoiled. If fine weather occurs again, as everyone may hope, could not the ground be well watered early without soddening to avoid such a nuisance?—J. HIAM, *Astwood Bank.*

—— THE HARBORNE GOOSEBERRY GROWERS' SOCIETY.—The eighty-third annual exhibition of Gooseberries was held on Saturday last. The entries were larger in number, but the size and quality of the berries were, owing to the dryness of the season, hardly up to the average of recent years. The premier prize was taken by Mr. T. Field with a "Leveller," weighing 20 dwt. 17 grains. Mr. E. Withers took second prize with "Ringer," 19 dwt. 15 grains; and Mr. W. Astley secured the maiden exhibitors' prize with "Leveller," 14 dwt. 6 grains. The class prizes were awarded as follows:—Twin berries: Mr. Field, "Ringer," 32 dwt.; red berries, Mr. E. Withers, "Bobby," 19 dwt. 11 grains; yellow berries, Mr. T. Field, "Leveller," 20 dwt.; green berries, Mr. H. Westwood, "Stockwell," 17 dwt. 8 grains; white berries, Mr. T. Field, "Antagonist," 19 dwt. 1 grain; six berries, Mr. T. Field, "Leveller," 112 dwt.; three berries, Mr. E. Withers, 53 dwt. 10 grains; two berries, Mr. T. Field, 35 dwt.; a consolation prize for the best beaten berry in the premier competition, Mr. T. Field, "Leveller," 19 dwt. 13 grains.

—— THE PLUM CROP.—Reports generally are not favourable with regard to the Plum crops, there being a universal expression of regret at the shortness of the supply forthcoming, both from fruiterers and growers. The spring frosts, no doubt, account to a large extent for this loss, and probably, too, the tropical nature of last summer, and the great depth to which the drought penetrated brought about debility and over-ripeness in the wood. The positions most generally assigned to garden trees is on the east and west aspect furnished by the walls, and in these gardens it is noteworthy that trees on the west side are bearing more freely generally than on the opposite aspect. This points to the influence of sunshine acting on frosted flowers in the early morning on the east, those on west walls being screened somewhat, and probably until the frost had lifted. Gages are very scarce, Kirke's, Jefferson's, Washington, and Coe's Golden Drop vary according to aspect, but not in any case are they plentiful. Victoria and Pond's Seedling on the west are the only trees bearing full crops, the same varieties on the other side of the garden are almost destitute, quite an unusual occurrence with these free-bearing varieties. Even Early Rivers gave a scanty return. The Plum crop is lighter than it has been for several seasons past in this neighbourhood. —W. S., *Wilts.*

—— EDUCATION IN GARDENING.—Mr. John Ettle, F.R.H.S., of the Agricultural Department, University College, Nottingham, and Instructor in Horticulture to the Notts C.C., has been appointed Staff Instructor in Horticulture to the Somerset County Education Committee.

—— GARDENING APPOINTMENTS.—Mr. H. Morse, late plant foreman at Trentham Gardens, has been appointed head gardener to Sir Cecil Miles, Bart., Leigh Court, near Bristol. Mr. G. H. Sage, head gardener at Ham House, Richmond, has gone in a similar capacity to Bayham Abbey, the seat of Viscount Lamberhurst.

—— MR. JAMES DOUGLAS.—After thirty-four years' service in the Whitbourn family, Mr. James Douglas retires in September in order that he may give the whole of his attention to his growing florist's business at Edenside, Bookham. Mr. Douglas has made greater progress in his ancient and honourable vocation than have most men. This is attributable to his good judgment and quiet, yet constant perseverance. When he first went to Loxford Hall as a very young man it was little better than a single-handed place with, we think, one greenhouse. He did not grumble, but worked, and his zeal was catching, Mr. Whitbourn being steadily, but surely, drawn into the vortex of gardening. He became an ardent florist and thorough horticulturist. His gardener could then have what houses, men, and materials he wished, and of these he made good use. When a removal was made to Great Gearies, a good garden had to be provided and equipped, this garden affording the utmost pleasure to its owner as long as he lived. He left Mr. Douglas secure in his position, also the requisite means for conducting his work as usual during the life of Mrs. Whitbourn. As this lady can no longer traverse the garden it has in a measure lost its charm to the manager, and it has been mutually arranged that he shall in future devote the whole of his attention to his own flowers, which, however, seem to become somebody else's as fast as they can be raised. Mr. Douglas is as active as ever he was; indeed, few men can get through more work, literary and otherwise, in a quiet way than he can, and his many friends will wish for him and his real helpmeet long and useful careers in their pleasant home at Edenside.

—— LADYBIRDS AND FRUIT PESTS.—Valuable information upon this subject is given by Mr. C. R. Marlatt in the "Year-book of the U.S. Department of Agriculture," in an article describing the various methods employed to combat the ravages of injurious insects in California, where the possibility of control of insects by introducing and fostering their natural enemies has been thoroughly tested. The very notable instance of the entire eradication of the white scale insect by the introduction from Australia of its ladybird enemy, Vedalia cardinalis, demonstrated the possibilities in this direction in the most striking way. This one experiment saved the State its Citrus industry, and gave the greatest confidence in many quarters in this means of controlling insects, as well as incited the later action looking to the introduction of beneficial insects on a much larger scale. It led the State of California, in 1891, to grant 5000 dols. "for the purpose of sending an expert to Australia, New Zealand, and adjacent counties to collect and import into this State parasitic and predaceous insects." Mr. Albert Koebele, who had previously been instrumental in introducing Vedalia cardinalis, was selected for the work. His chief object was to obtain predaceous insects which might exterminate the black scale, the red scale, and the San José scale. Mr. Koebele's mission lasted upwards of a year, and during this time he imported into California probably 60,000 specimens, representing very many species, chiefly of ladybirds. Five or six of these species took hold well from the start, and two or three of them are still represented abundantly in the orchards of California, the others having practically disappeared. The important ones remaining include a very efficient predatory enemy of the black scale in the little Rhizobius ventralis, and two much smaller species, R. debilis and R. toowoombæ, which attack the black scale, and also the red scale and San José scale to a less extent. Rhizobius ventralis was easily colonised, and during the last three years has been distributed in enormous numbers to different parts of the State, 300,000 or 400,000 having been colonised in Southern California alone. This beetle is by far the most useful of the recent importations, and has already done much good; in several instances it has effected the entire eradication of the black scale in badly infested orchards. The disappearance of the scale may in some cases be due to other natural causes, but there seems to be no doubt that the chief credit belongs to the ladybirds. Once the ladybirds have established themselves in sufficient numbers, it seems best not to spray or fumigate the trees, as these treatments are very prejudicial to the multiplication of this beneficial beetle.—("Nature.")

—— Abbey Park Show, Leicester.—An interesting ceremony took place in connection with the above last week, when Mr. Alfred Outram, F.R.H.S., presented to Mrs. J. Burn, the wife of the much respected curator, a valuable gold watch and chain, in appreciation of her great attention and kindness to horticulturists for many years. The amount was subscribed for by the judges, exhibitors, and other horticultural friends, and came as a most agreeable surprise to the recipent.

—— Hemp Cultivation in Bologna.—One of the most important agricultural products of the provinces of Bologna and Ferrara is Hemp (Cannabis sativa). Bologna Hemp is generally manufactured into yarns and canvas. The Ferrara quality is principally used for rope making. The former is a finer fibre than the latter, but not so strong; they are both, however, held in high esteem in textile centres abroad, according to the United States Consular Agent at Bologna, chiefly in Germany, France, and Spain. The cultivation of Hemp has greatly developed in Bologna and Ferrara owing to the favourable conditions of the climate and soil, which are not easily found in other countries. Hemp may be cultivated between the Equator and 60° latitude Chemically the land must be siliceous, argillaceous, calcareous, and rich in azote. Physically it must be soft, fresh, and deep. In addition the land must be abundantly manured. Sowing generally takes place in the spring, owing to the necessity of a temperature of 46·4° Fahr., and a moderate degree of humidity. It is preferable to sow by machine, this system saving seed, and the sowing being much more regular. The land must be previously deeply ploughed. After sowing the land requires to be hoed; and much other work is necessary, such as the extirpation of weeds, in order to obtain an abundant crop. The crop ripens in August or September, according to the weather. It consists of stalks about 3 mètres long. These stalks are placed in bundles and put into ponds expressly constructed, where they remain about a week. They are then dried and scutched by means of a complicated process, which produces the fibre ready for market.—("Journal of the Society of Arts.")

—— Edinburgh School of Rural Economy.—The prospectus of the Edinburgh School of Rural Economy for the session 1897-98 has now been issued. Under the care of an influential Board of Management, appointed jointly by the University of Edinburgh, the Highland and Agricultural Society, the Edinburgh Town Council, and the County Council of Mid-Lothian, these classes have met with great success, and have been highly appreciated. In each of the last two years over 200 students attended the classes. The courses of instruction arranged for the session 1897–98 are similar to those of last year. Their main features are :—1, A two years' curriculum of day classes in agriculture and allied sciences; 2, a course of day lectures on forestry in the University; 3, an extensive series of evening classes on agriculture and allied sciences, embracing horticulture and forestry; and 4, the usual summer vacation classes for schoolmasters, which have been well attended. The day classes extend over two sessions, each beginning in October and ending in March. It is expected that those entering for these classes will have previously completed a good general school training. The work of the first session, embracing mensuration, mechanics, elementary physics and chemistry, botany, book-keeping, drawing, and handicraft, practically completes the preliminary education of the student, and gives him an adequate knowledge of the elements of the sciences that have a direct bearing on agriculture. At the same time his interest in the practical aspect of his work is maintained by such class exercises as those in measuring buildings and fields, in making drawings of these to scale, in woodwork, and in the application of physics in agriculture. The subjects of study in the second session are agriculture, agricultural chemistry, botany, zoology, and entomology, veterinary science, and forestry. The complete course thus aims at fitting a young man to enter with intelligence into his work as a farmer, a gardener, or a forester. It should enable him to understand the greater part of the work that he will see in practice, and to study for himself any special subject that he may afterwards find to be of importance to him. A student who has satisfactorily completed the two years' course of study, and who has had the required experience of practical work on the farm or in the forest, should find himself sufficiently prepared for the examination for the diploma of the Highland and Agricultural Society. Numerous and varied evening classes are provided for those who are otherwise engaged during the day. A specially moderate scale of fees has been arranged. This will be indicated by the fact that the inclusive fee for the first year's entire course in agriculture is 5 guineas. Copies of the Syllabus are to be had from the Secretary, 3, George IV. Bridge, Edinburgh.

—— Huyton Show.—In our report of the Huyton and Roby Show in last week's issue Mr. Oldham was credited with having won first prize in all Grape classes, whereas the winner for Black Hamburghs was Mr. Eaton, gardener to Jno. Parrington, Esq., Roby Mount, Roby, Mr. Oldham being second.

—— Weather in South Wales.—The following is a summary of the weather here for the past month :—Rainfall, 2·29 inches; greatest fall, 1·06 inch on the 25th. Number of days on which rain fell, eleven. Maximum temperature, 98° on the 11th. Mean maximum for the month, 79·9°; mean minimum for the month, 47·9°, with a minimum of 34° on the 7th. The wind was in the W. and S.W. for twenty-three days. Very cold winds the beginning of the month, but the latter part has been very hot and dry.—W. Mabbott, *Dowlais.*

—— The Weather Last Month.—July gave us more sunshine than usual, also a heavy thunderstorm on the 26th, which measured 1·28 inch of rain in an hour and a half. This is the largest amount registered here for one day since October 2nd, 1892. The wind was in a northerly direction nineteen days. Total rainfall, 1·70 inch; this fell on eight days, and is 1·12 inch below the average for the month, the greatest daily fall being 1·28 inch on the 26th. Barometer (corrected and reduced): highest reading, 30·390 inches on the 11th at 9 A.M.; lowest, 29·614 inches on the 20th at 9 A.M. Thermometer: highest in shade, 83° on 24th; lowest, 42° on 8th and 11th. Mean of daily maxima, 71·96°; mean of daily minima, 51·16°. Mean temperature of the month, 61·56°; lowest on grass, 37° on the 8th; highest in sun, 145° on the 12th. Mean of earth at 3 feet, 59·22°. Total sunshine, 217 hours 5 minutes. There was one sunless day.—W. H. Divers, *Belvoir Castle Gardens, Grantham.*

—— A Darwin Memorial.—Shrewsbury was *en fête* on Tuesday on the occasion of the unveiling of a memorial statue to the late Charles Darwin on a site in front of the Free Library (formerly the old school where he was educated) given by the Corporation. The statue, which cost £1000, is the gift of the Shropshire Horticultural Society, whose President, Lord Kenyon, unveiled it at noon in the presence of a distinguished company. The statue is beautifully executed in bronze by Mr. Horace Montford, who, like Mr. Darwin, was born in Shrewsbury. The work, which has been excellently done, stands on a pedestal of Swedish granite, supported by steps of Dartmoor grey granite. Lord Kenyon, after a few happy words as to the occasion of the gathering, called on the Mayor to take charge of the statue, which the Horticultural Society so generously presented to the town. A public luncheon followed in the Music Hall, presided over by Lord Kenyon, and among those present were the Mayor and Mayoress of Shrewsbury, the Bishop of Shrewsbury, Sir Joseph and Lady Hooker, Professor Darwin, F.R.S., Mr. W. E. Darwin, with the Town Clerk of Shrewsbury, the architect, and the Hon. Secretaries (Messrs. Adnitt and Naunton) of the Shropshire Horticultural Society.

—— Destroying Weevils.—The recognised method of destroying weevils and other seed-infesting insects which cause serious loss to seed and grains, both for sowing and for food purposes, in the United States is to treat them with the fumes of carbon bisulphide at the rate of 1 lb. to 100 bushels. This chemical is a colourless liquid, but when exposed to the air the sulphur and carbon separate, each uniting with the oxygen, forming a carbon oxide and sulphur dioxide, the latter of which is a very poisonous gas with a disagreeable odour. To ascertain whether seeds treated with this chemical lose their germinating capacity an experiment was made by the Division of Botany in the Department of Agriculture, in which seeds were exposed to a saturated atmosphere of carbon bisulphide for forty-eight hours. They were then placed in a germinating chamber in which check lots of untreated seed were also tested. The result was that the germinating percentages of almost all the seeds treated and untreated were the same, although in Barley, Rye, Wheat, corn, Crimson Clover, Millet, and Rice this extreme treatment caused some injury. The varieties which were damaged by an exposure of forty-eight hours were then put to another test of twenty-four hours' duration, and the result seems to be that in general the seeds of Cotton, Peas, Beans, Buckwheat, Oats, the Cabbage family, and Cow Peas will endure severe treatment with the fumes of carbon bisulphide without losing their germinating quality to any appreciable extent, while on the other hand seeds of corn, Wheat, Rye, and crops belonging to the Grass family, except Kaffir Corn and Oats, should be treated with caution, since a deterioration in vitality is likely to result from excessive exposure to the gas.—("Garden and Forest.")

—— THE TOMATO.—The Tomato is rich in possibilities in the hands of a skilful cook. It can enter into and give tone to endless soups; it can be made into purees and sauces and stews; it can be eaten *au gratin*, with maccaroni or vermicelli, and *en salade*. There is no reason why it should not be seen more often on our breakfast tables. Carefully grilled, and placed on slices of grilled fat bacon, it makes a delicious dish. Then, again, we can stew it, place it at the bottom of a dish, and gently deposit thereon poached eggs; or we may vary this by placing scrambled eggs round a pyramid of stewed Tomatoes. *Farcie* they can be introduced at breakfast, lunch, or dinner; and, as a writer justly points out, "*farcie* Tomatoes may not easily be surpassed. Upon your whim or choice it will depend whether you stuff them or cut them in half for so ineffable a purpose. And upon your whim likewise depends the special forcemeat used. Chopped Mnshrooms, Parsley, and Shallot, seasoned with discretion, leave little to ask for. Prepare, instead, sausage meat, Garlick, Parsley, Tarragon, and Chives, and the Tomatoes so stuffed you may without pedantry call *a la Grimod de la Reyniere*. But whatever you call them, count upon happiness in the eating."—("Epicure.")

CARNATIONS AND PICOTEES.

IN writing about Carnations and Picotees it behoves one to wield a reverent and careful pen, for these are "florists' flowers," and thereby hangs the red light of danger. Your average florist is a worthy fellow enough, and, to give him his due, he is whole-souled in his desire to foster and improve the flower of his choice; but he must be indulged and humoured, his work must be criticised with caution, and his hobby must not be tilted at recklessly. He sets up a certain standard of excellence; he institutes given points of merit, and according as results approach or deviate from these so follows approbation or condemnation. But let us define the term florist a little more clearly. The suburban amateur will tell me that there is a man along such a road who calls himself a seedsman and florist, and who entices irresolute dyspeptics by announcing "Cucumbers fresh cut from the vine," or those on the look out for something bright and economical for the flower garden with an announcement of "bedding plants for sale cheap." Is this the kind of man referred to? No! The florist, as I wish him to be understood now, is a specialist, whether amateur or professional mat ers not. In years gone by he, or his predecessors, has taken in hand some particular flower, and has worked it up on clearly defined lines to a point at which it would hardly be recognised by the one who commenced with it. The Rose is an instance, the Carnation a second, the Pansy a third. Improved varieties have been raised, and to these names have been given, until, in some cases, they are numbered by hundreds. Naturally they are not all markedly distinct; but points of difference can be found by the trained eye when the varieties are compared. Perhaps some readers will have been a little surprised in sending a Rose, a Pansy, a Carnation, an Auricula, a Calceolaria, a Petunia, or a Cineraria (all these are florists' flowers) to be named to find themselves referred to a notice that florists' flowers cannot he named. Editors, they may have thought, know everything. In a general way they do, but after what has been said about the weakness of florists for manufacturing infinitesimal distinctions and then giving names to them, it may not be so much a matter of surprise for the human encyclopædia to decline making himself acquainted with every detail of their doings.

There cannot he the smallest doubt that immense good has been done by the specialist or florist—call him which you will—in improving many of our most useful flowers. Could every reader of these lines look upon the progenitors of some of the most beautiful and valued flowers that adorn their gardens to-day, they would not be able to withhold a tribute of admiration, and even of respect, for the patient and careful toil of generations that has led up to such results. Now that the culminating point has been reached a little artificiality creeps in. This is not surprising. The florist's watchword is progress, and we must try to forgive him if, now the apogee of excellence is reached, he establishes points of merit which are not gained by legitimate natural development, and are therefore added by artificial means. With Carnations and Picotees the perfect show bloom must be circular, with regular tiers of petals overlapping each other and rising to the centre. Of course the geometrical exactitude is not there as the flower is cut from the plant, and, as it is indispensable for prizewinning, ivory implements are brought into requisition to dispose the petals in the required form. Opinions differ as to whether this is excusable. The florists have done so much for us that it would be ingratitude to denounce them strongly; but assuredly it is not gardening to restrict a plant to one bloom, to adopt every imaginable means of securing a perfect flower, and then to resort to such means as have been indicated for improving its shape. What is it but a confession of failure? It has been criticised repeatedly and severely in the past by those who plead for more natural treatment, but it is absolute waste of time and thought, of ink and paper, to attack the practice of dressing flowers and pass unnoticed the points in the attainment of which the practice gets its rise. This does not apply to Carnations only, but to Roses, Dahlias, Chrysanthemums, and nearly every other prominent florists' flower. While certain qualities are recognised in adjudicating upon the merits of a bloom, and these qualities can be added or heightened by artificial manipulation, dressing will go on, and if not practised openly it would be practised secretly. The cause must be looked to, not what is really only an effect. Truly a little common sense is sadly wanting.

To those who cultivate Carnations and Picotees, as they cultivate other flowers, solely for the adornment of their greenhouses and gardens, the dressing bubble and other burning questions of the exhibition tent, can only awaken a smile. Who need vex his soul about a misplaced petal—misplaced, that is, according to the florist's ruling—when he can look around his garden and see a thousand beautiful blooms brightened with a hundred hues, graceful and sweet enough for the most refined home? He can be grateful for what the florist has done in the past in raising so many admirable varieties, and utilise them freely for his own purposes. The great value of the Carnation lies in its adaptability for outdoor and indoor cultivation, and from the fact of its doing well in town gardens. It should be a comforting thought to every townsman that, if he cannot grow the Rose, this great flower is not forbidden to him too. Visits to country gardens may reveal to him what he loses from the impurities of his own atmosphere, not, sometimes, unmingled with a touch of sadness awakened by the splendour of the Rose or the modest but powerful charms of the Violet; there is, however, consolation in the thought that if his sphere of work is limited, there are within the bounds some of the noblest treasures of Nature's exhaustless store from which the purest and richest pleasure may be derived. If in respect to the Carnation the most recent examples of the improver's handiwork are not coveted, there still remain innumerable free-flowering and useful varieties with which beds and borders may be enriched. Their names might not awaken interest in the florist, nay, they may own no names at all, but their beauty and perfume are there just the same, and in the sick chamber or the drawing room, not less than in the garden, they will worthily fill their allotted place.

To those dwelling in country districts, and quite unfamiliar with the general character of town gardens, it would seem superfluous to plead for still wider recognition for this valuable hardy flower. There, every cottage plot has its Pinks and Carnations, common varieties enough, but serving their purpose well. In town enclosures it would be a real pleasure to meet with the commonest of them all. The thousands who find pleasure and benefit from growing flowers in the neighbourhood of our great towns are but a tithe of the vast population there—a huge mass of humanity unleavened by a single refining influence. It would be a great thing if these could be taught what flowers could do for them. Carnations will flourish where many tough things in the way of plants fail to thrive, and are capital flowers for tempting the lazy or heedless into a start in gardening life. As is known, they will do very well in common soil, and present no difficulties of culture to quench budding ardour.

An easy way of getting up a stock of plants is by raising them from seed. So simple is this, and so satisfactory the results, that it is not easy to understand why it is not more general, at all events among amateurs. Possibly the expensive nature of choice seed acts as a deterrent; but if the catalogues are carefully scanned it will often be found that mixed seed of border varieties is offered at a fourth or fifth the rate, and from this plenty of plants can he raised well adapted for adorning modest borders. Seed sown one year—and the earlier the better—will produce excellent flowering plants the following summer. I have seen many laden with flowers about fifteen months old, but if sown in summer the plants will still bloom the following year. The seed is best sown in shallow boxes with a piece of glass placed over the top, in a shady corner of the garden, and the plants pricked out before they have time to crowd each other. If extra strong plants packed with flowers are required, sow under glass in February or March, keep the plants stubby and sturdy, and when planting out time arrives they will have a long season of growth in which to store up energy for a future display.

Easily as Carnations are grown it is not advisable to neglect them. After flowering they become crowded and woody if not attended to. Far the best plan with any approved varieties is to layer them while the growths are young and succulent, and these layered portions will make better flowering plants the following year than their parents. As a rule several flowerless shoots can be found towards the base of the plant. Place a mound of soil round each, draw down the shoots, tongue them by pressing the blade of a sharp knife about half way through the growth, and then turning its direction and making a parallel incision in the shoot about an inch long, ending just through a joint, and peg them to the mound with hairpins, pressing the cut part into the soil. Roots will form, and in about six weeks or two months the shoot can he severed near the old plant, and the young one left to cater for itself in future. If a frame is possessed the young plants may be lifted, potted, and wintered in it; if not, plant them where they are desired to grow. Those purchasing Carnation plants can do so either in autumn or spring, as they may be planted at either season.

I do not propose to enlarge upon the florists' distinctions in the present article. As Carnations and Picotees are the flowers of the season, so they are treated upon, and as border Carnations are grown in a hundred gardens where there is but one devoted to show flowers, so the flowers of the majority must be thought about first. Shows may assist in the work of education; but after all, the best lessons are learned from the cultivator's own home plot, and the greatest pleasure is derived from the results of his own work. Whoever makes a garden attractive, in however simple a way, is in some sense a teacher, and he has reason to be proud if he produces something from which an example may be copied, and encouragement derived by a beginner anxious to follow in the same pleasant path.—P.

The Orchid Hybrids.

We have received a copy of the supplement to this book, in which the author fulfils his promise to keep orchidists abreast of the times in the matter of hybrids. As before, we have little to say for or against the method of classification followed in the book, for all such systems are necessarily incomplete as long as botanists are continually altering their views with respect to specific rank or otherwise of certain plants. Possibly at some future time we shall see the futility of all this overwhelming nomenclature, and admire our Orchid hybrids as we do those of many other families without giving a separate name to every one that shows the least variation. In a manner, Mr. Hansen's work tends this way, and his compilation of all the hybrids of which he could gain any tidings is a monument of painstaking and hard work. For this he merits unqualified praise, and those interested in raising or naming seedling Orchids should procure a copy.

Sobralias.

These lovely Orchids have one fault; it is well known. Were the flowers less evanescent there is hardly a genus to compare with them for beauty. The tints of such as S. xantholeuca, the golden centre to the lip first merging into a delicate creamy yellow, then almost pure white, are more beautifully graduated than those of any Orchid I know. The chaste and rare white forms are not equalled by any of the albino Cattleyas, grand as these undoubtedly are; while other forms, such as S. Veitchi (fig. 21), with a white ground and violet edging, so faint as to appear to he only suggestive, are unrivalled for delicacy by the choicest Picotee.

As a set-off to the fleeting character of the individual blossoms there is the fact that these are produced successively over a long season. In habit they are all very similar, but in height they vary from a few inches only in such as S. sessilis or S. macrantha nana to the typical form of the latter, which reaches a height of 6 feet and upwards. In fact there are species—though these are probably not in cultivation—that have immense stems more than three times this height. Such kinds would be rather unwieldly in present-day Orchid houses, so probably collectors give these a wide berth.

Sobralias are natives of tropical America, and all the species may be accommodated in a house kept at an intermediate temperature. The roots are usually strong and rather gross feeding as Orchids go, but though these delight in abundant moisture they are very easily injured by a close inert mass of heavy material about them. In preparing the compost this should be kept in mind. Peat is a good material for them, but if used alone it is apt to decay too quickly, and though the plants do well as long as t is sound they soon go back when it loses its condition. Add to the peat a little good loam—for the lasting character of loam fibre is not sufficiently known among orchidists—chopped sphagnum moss, and a liberal allowance of charcoal and potters' ballast.

This, while forming a good rooting medium, will not hold moisture long enough to be injurious, and, combined with perfect drainage, should go far to make their culture a success. When the plants are newly imported they may with advantage be kept up a little in their pots, but established specimens do not need this attention. The former, too, will not usually require quite so liberal a reading of compost for the first season, as it is better to be satisfied with medium-sized growths such as are produced thereby than to run the risk of losing the young roots. The first tiers of these that are produced on any description of Orchid should be studiously preserved, as they serve to give the plants a good start in their altered conditions of life.

While not, of course, disturbing the older roots of established plants more than is necessary, be careful not to place any old decayed or sour material in the new pots, for if young roots reach this they are sure to be badly checked to the lasting injury of the plant. A little thought should be given to the size and habit of each species when potting those of the most vigorous kinds needing more room than the smaller growers. In repotting place the new compost firmly, but do not ram it tightly, as it is imperative that air as well as water percolate freely through the layers, and place a nice film of rough moss over the crocks.

The atmosphere should be kept moist all the year round, the driest time being while the flowers are open. When growing the syringe may be freely plied about the foliage and stems with advantage, this serving to keep their insect enemies in check. The growth should not be allowed to get too much crowded, as this prevents air and light from reaching all the leaves. Old specimens then may have a few of the stems that have flowered cut out when the new ones are about half formed; no check will be given the plant by doing it at this season. From the time the young growths start until late in autumn Sobralias all like a very free supply of water at the roots, and although this may be lessened during the winter months they must not be allowed to get quite dry at any time.

One of the most beautiful kinds is S. leucoxantha, the sepals and petals of which are pure white, the lip also white with a golden yellow centre. S. xantholeuca, noted above, is equally charming but a little deep in colour. S. macrantha is perhaps the best known of all, the large flowers of which are of varying shades of rosy purple, with a very broad lip of rose and yellow. The only tint of colour on S. kienastiana is a yellow one at the back of the lip, while S. m. nana, as its name implies, is a dwarf form of the type.

S. sessilis is a rare and pretty kind, with very little colour in the flowers, and this chiefly confined to the lip, which is yellowish flushed with rose. This does not exhaust the list by any means, and there is no reason why the smallest grower of Orchids who cannot spare room for large plants, such as S. macrantha, should not give up a corner to some one or two of the dwarfer but superb kinds.—H. R. R.

TOMATO NOTES.

I am led to think that a few plain and simple remarks on interesting points in Tomato culture adapted for the season—that is, the present time, would probably be of some service to growers who may not have had much experience, and who welcome any hints likely to render them assistance.

Essential Points.

A constant multiplication of healthy rootlets must be induced in the early stages and, as far as possible, continued during the full growth of the plants. This activity of root action when confined within reasonable limits is a great help to the free setting of the bloom. I have frequently noticed that by any acceleration of the production of fine root fibres, a good set is produced, and the young fruits swell freely. It is a good custom with many growers to aid the distribution of the pollen by gently tapping or shaking the bunches of bloom with a padded stick or the fingers. This operation insures fertilisation more surely when the root action is vigorous.

Another essential point is light. Tomatoes seldom obtain too much sunshine. Growth under favourable conditions is rapid, and all possible sunshine is necessary for its concentration in the most desirable parts. Hence it is imperative that advancing growth at least should be near the glass.

A free circulation of air assists the light and sun to complete their work. At the present time of the year Tomato houses ought never to be wholly closed. The amount of air allowed to circulate may be regulated by reducing the spaces where air is admitted should the weather prove ungenial, and there is experience of cold and damp. In the latter case fire heat will be helpful, serving as it does to dissipate damp, rendering the atmosphere buoyant and dry. Freely admit air all the time fire heat is employed, so that the temperature is not raised above the normal height and is regular. Fungoid diseases do not attack plants so treated.

Every shoot required to bear fruit must have free extension and space to develop its foliage without unduly crowding. There is a mistaken idea prevalent that as soon as Tomato plants have formed a number of principal leaves these ought to be mutilated by cutting back in order to cause the plants to fruit. The leaves do good work provided the space they require is ample. It is true that portions of leaves may sometimes be cut away with advantage, this being chiefly when overcrowded. The lower leaves of plants gradually become useless, turn yellow, and decay, especially when the fruit in their vicinity is ripe or ripening. The leaves are then serving no practical end, and may be cut out entirely, while others may be gradually reduced so that the fruits may be fully exposed to complete their ripening.

The application of moisture to the roots is another point of leading importance. Without sufficient water to moisten the lowest roots the plants do not thrive properly, setting and swelling bunches of fruit in succession as they should, at the same time gradually making new growth.

Tying and Stopping.

A rigid system of suppressing the side shoots must be adopted on each stem retained for producing fruit. The number of main

stems ought to be early decided upon, though in the majority of cases the single stem system is the best. Each main stem requires a foot to 15 inches space. The side shoots spring from the axils of the leaves during the whole time of active growth, and should be rubbed out when small. Until the plants cease to grow and form fruit, side shoots are produced. Stopping the leader and allowing a fresh one to form, is not a good practice in my experience. There is no difficulty in securing a good set with the uninterrupted extension of the original stem. When the space is filled, the growths must of course be stopped.

With planted-out Tomatoes receiving good treatment at the roots, the upper growth assumes a vigorous and healthy character, which it may seem a pity to check. Under such circumstances, the stems down over the roots immediately a number are found ramifying near the surface. Repeat a similar dressing each time roots appear on the top.

Feeding.

Top-dressing is a form of feeding, but the term usually implies the application of liquid manure. Strong liquid nourishment is not required immediately after a liberal top-dressing of compost; but when the roots are working freely in the latter, and before more is applied, a few doses of some clear liquid manure will be of immense service. The drainings of general farmyard manure diluted to a safe strength are appreciated by Tomatoes. Clear soot water is excellent, also solutions of guano or any artificial

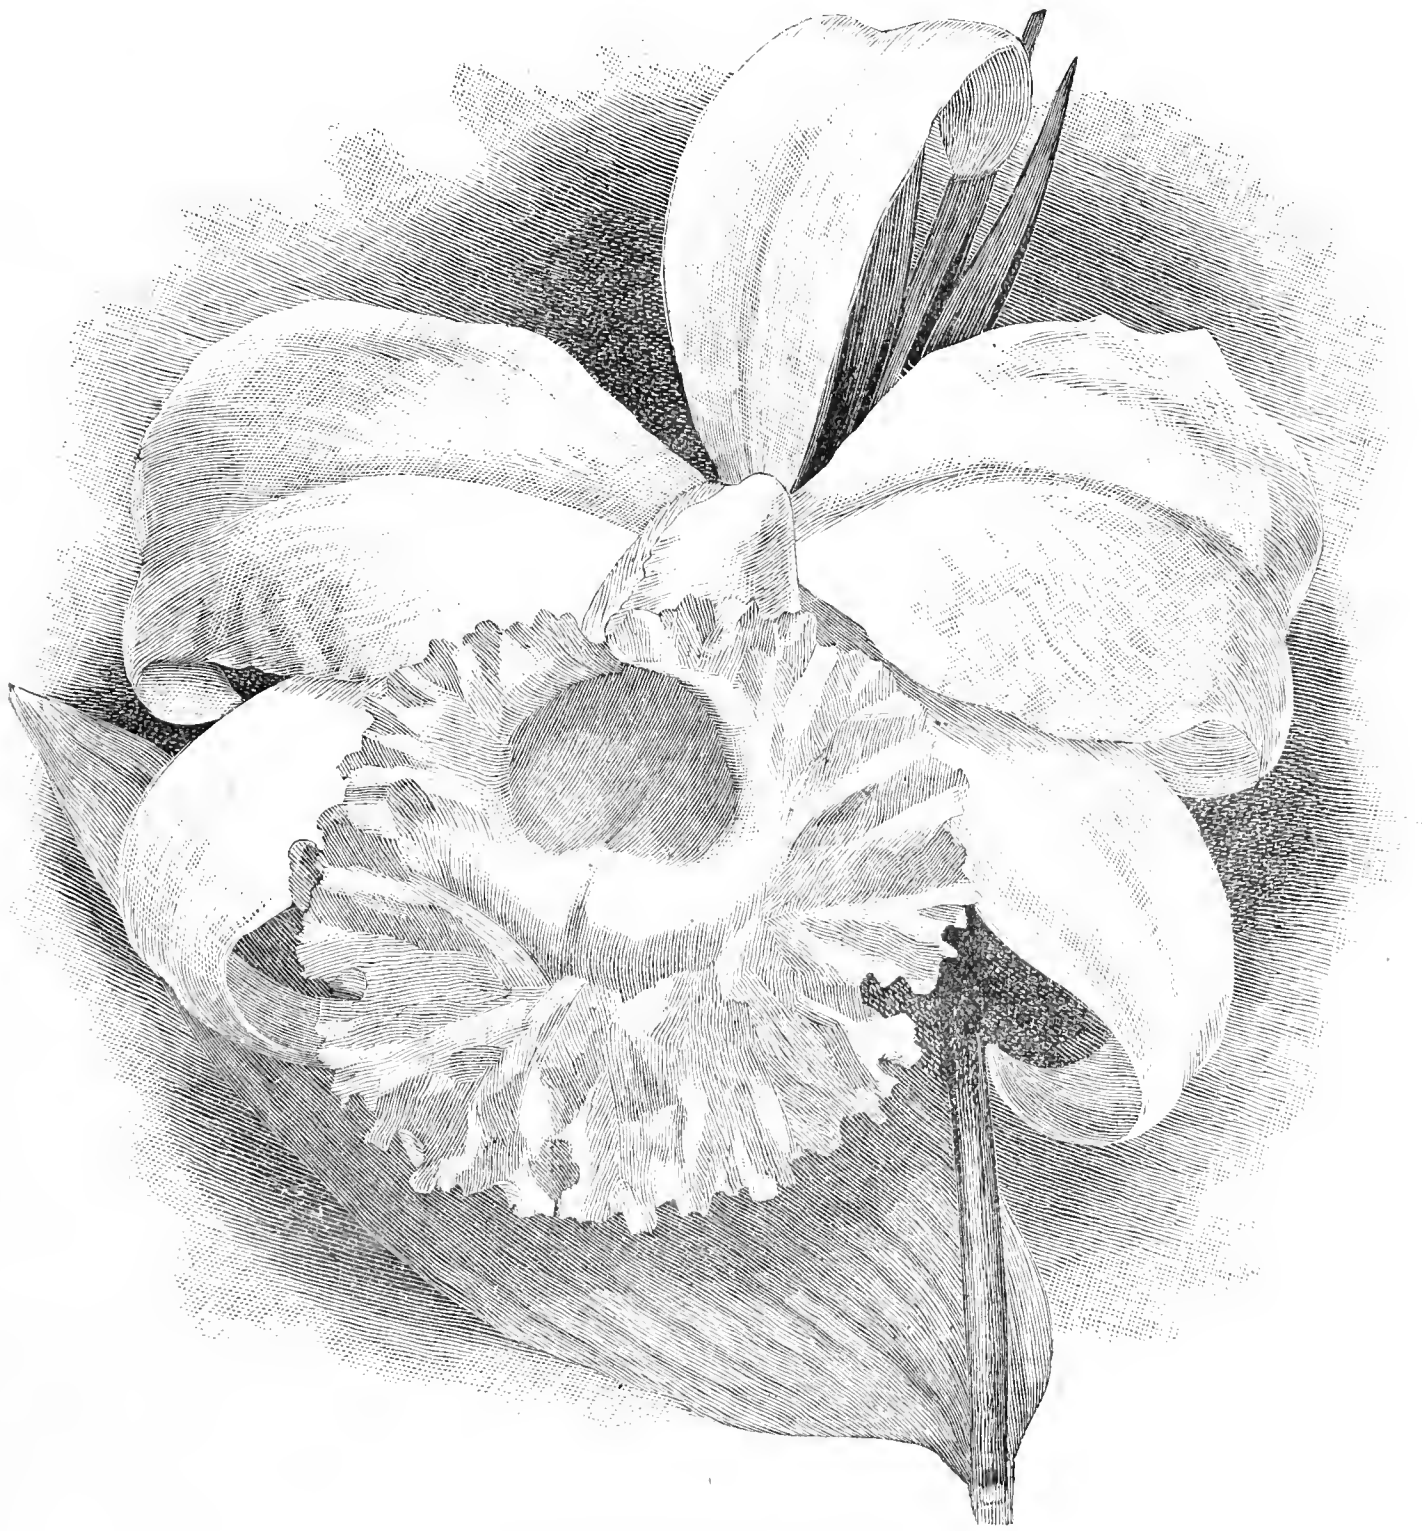

Fig. 21.—SOBRALIA VEITCHI.

being trained on wires or upright to stakes, I have bent the lower and barer parts, and thus afforded more room. Keep the plants well tied to the wire or stakes.

Top-dressing.

Tomatoes in the early stages of growth are best when not allowed too much root run if they are planted out, or large quantities of soil when grown in pots. They like sufficient to promote healthy, vigorous growth, and the formation of the first flower trusses and bunches of fruit. Top-dressing then comes in of great service, fresh rootlets being formed in it which meet the increasing demands of the plants. The additions which are thus made may consist of rich material. Equal parts of loam and manure, with the addition of a little bonemeal, crushed charcoal, and wood ashes, together with an admixture of a general fertiliser at the rate of 2 lbs. per bushel of soil. A layer of this may be pressed firmly fertiliser at the rate recommended by the vendors prove serviceable.

Liquid manure ought not to be applied indiscriminately, but always with a full knowledge of the wants of the plants. On no account give it when the soil is very dry, because it cannot have the best effect, and is wasteful. A copious supply of clear water given first will render the soil in a fit condition for retaining the fertilising elements and assisting the roots. Plants in pots and bearing good crops require constant and regular attention in top-dressing, feeding, and watering.

Fruit Ripening.

The lower bunches of fruit colour first, the higher bunches swelling in various stages at the same time. The feeding and watering required to sustain the latter frequently causes the ripe fruits to crack. This may be avoided by picking the half-coloured

fruits as they become ready, finishing the ripening on a warm, sunny shelf, where they colour as rapidly as on the plant without any deterioration in flavour.

It is at the period of ripening that the leaves near the fruit may be reduced, or any of the lowest ones which have ceased to perform the functions of green leaves may be removed. Portions of large leaves unduly shading the fruit may be cut out, and when the full crop of fruit has ceased to enlarge in size, growth being practically finished, the leaves may be gradually reduced.—E. D. S

GROWING CAMELLIAS.

In writing on the culture of Camellias, it is scarcely necessary to enter into details of propagation, as ninety-nine out of every hundred private growers purchase plants. We have both raised stocks from cuttings, and attached to them, by grafting, the best varieties; but it is, as a rule, far better to let nurserymen who have special conveniences for the work establish the plants, especially as they can do this without any great outlay, and healthy examples of good varieties are consequently the reverse of costly. Briefly it may be said, for the information of those who desire a little knowledge on the subject, that cuttings of matured growth with a heel of the previous year's wood emit roots the most freely. They are inserted as closely together as possible in well-drained pots of sandy soil in September, placed on ashes in a cool pit or frost-proof frame, shaded as needed and kept moist. There they remain until the spring, and there they may remain until rooted, though they are often placed in a little heat after growth commences Eventually they are potted singly, and when established and growing freely they are partially cut down. Scions are attacbed to them by taking a slice off the bark of both stock and scion, fitting the two together, securing them with matting, covering with moss or grafting wax, and keeping them in a close propagating case until the union is complete. The growth of the stock is then gradually reduced and shortly removed down to the scion, which now and onwards appropriates the whole of the supplies of the roots. This is propagation in a nutshell; but, as before observed, it is better to purchase established plants.

Are home-raised or imported plants the most desirable to purchase? is a question often asked. The truth must be told on this matter. Healthy free-growing plants raised in British nurseries are far more likely to succeed in the hands of the majority of amateur cultivators than imported plants are. The latter plants are often luxuriant, yet almost as often deteriorate when placed in English greenhouses. The change of treatment and locality is too sudden and great for them. After these plants have been prepared for a year in our nurseries, acclimatised, they do very well; but cheap imported Camellias are often dear in the end. In purchasing Camellias, then, the safe course is to obtain established plants from home nurseries, giving preference to those raised there, provided—and this is important—they are free and strong, a stunted home-raised plant being decidedly inferior to a free yet sturdy acclimatised foreigner.

It has been said that Camellias are easy to grow, and they certainly are when the plants are healthy to begin with; but stunted, scraggy, half-starved plants with brown-blotched leaves, dry and harsh, are not easy to manage, and cannot quickly be restored to health and vigour. Many such plants can be improved without doubt, and even some be transformed into handsome specimens; but time and skill are requisite for effecting this desideratum. But what is the reason of so many Camellias being in the unsatisfactory state indicated? The initial cause in not a few cases is commencing with immature, strong-looking, but really weak, because plethoric plants, and then treating them wrongly. They have had generous treatment, specially prepared soil, pots packed with roots, so as to endure any amount of water, liquid manure periodically, and a very moist position, either in pits or shaded places in the open air, and too often have been so drenched and saturated in the autumn as to cause incipient decay of the roots. Place such plants on an open stage in a dry and draughty greenhouse, and note the results. The very life of the plants evaporates through their great broad leaves; pale brown blotches appear, which spread, the edges of the leaves curl back, and eventually the foliage withers and falls, and as there is no stamina in the plants they cannot put forth fresh strong growths. This is the treatment accorded to the majority of such plants by amateurs, and it is wrong. If they repot the plants as soon as they arrive, as many do, this makes matters no better, but rather worse; for they disturb the roots and have no compensating advantage, for the roots will not move under those conditions. Such soft pampered plants, which have been treated almost as semi-aquatics, must not at first be placed on latticework stages in dry houses, but have a sojourn on moist ashes in a pit or frame, and be very gradually inured to the differing conditions under which they are intended to be grown. It is not suggested that all foreign Camellias arrive in a half succulent state, but vast numbers are in the condition described, and it is well to know what to do and what to avoid under the circumstances.

Now to another class of plants—those that were healthy once, but are now unsightly. What is the cause of the change? Overpotting, with overwatering immediately afterwards, have together formed the first step on the road to ruin of hundreds of plants. Camellias are water-loving plants undoubtedly—their white, fleshy, Hyacinth-like roots tell us this, but stagnancy they abhor. Even a Hyacinth will not grow in mortar, and a Camellia's roots are far more sensitive. If there is a suspicion of saturation or sourness they are poisoned, turn brown at once, lose their absorbent power, and the plant starves surrounded with plenty.

In potting a Camellia let the pot be as small as possible—only just large enough to admit the roots, with the necessary space for pressing down the soil. This is the safe course to pursue. Let the soil be moist when used, but not decidedly wet, that already surrounding the roots to be in exactly the same condition. Press the new soil as firmly as the old, and do not bury the stem too deeply. Syringe the plant and pot three or four times a day if needed, shade it, do everything to retard the first watering, yet do not permit the soil to be dry. The object should be to induce the roots to move before water is applied. This secured the rest will be easy. Apply water judiciously, yet increasingly, as the growth and season advance, and when the pot is filled with roots and the drainage ample, as it must be, the supplies can scarcely be too copious. The soil, then, must always be moist—not sometimes only, but constantly, even if water has to be given twice or thrice a day; and if something more is needed, top-dress with soot and bonemeal alternately for sustaining and enriching the colour of the foliage. This is better than constant shiftings from pot to pot. There is no fear of saturation in the growing season if the pot is crowded with roots and the drainage thoroughly efficient, but it never will be full of roots if the plant is first overpotted and the new soil is rendered stagnant at once. This is the real root of the matter, and should not be overlooked.—J. H.

ISLE OF WIGHT.

Brighstone.

During the last week in July the rural cottage garden societies in the Garden Isle have been busy holding their exhibitions.

On July 27th the Brighstone Society got together over 400 exhibits, most of them being of excellent quality. Amongst the principal exhibitors were Messrs. Creeth, Sprake, Warne, Cooper, Watson, Hawker and Went. The Rev. G. E. Jeans secured premier honours for Roses. Amongst the many exhibits not for competition were groups by Sir Chas. Seel, Lady Mary Gordon, and a collection of run and section honey by the Rev. L. B. Morris. The day was beautifully fine, and everything passed off without a hitch.

Arreton.

On July 28th the picturesque and fertile valley of Arreton was all gay by bunting and flags in and around the vicarage grounds, where the flower show was to be held. The exhibits staged were not so numerous as in the previous year, but there was an improvement in the standard of excellence all round. The competition was very keen in most classes, particularly for Potatoes, Onions, Peas, Beans, Gooseberries and Currants. A magnificent dish of the latter (Raby Castle) secured for Mr. Geo. Lipscombe, the Isle of Wight Horticultural Improvement Association's certificate for cultural merit. The principal exhibitors were Messrs. W. Clarkson, J. Boyce, Hookey, Orchard, Lipscombe, Rashley, and J. R. Blake. The honey classes were well contested.

Carisbrooke.

The local Show of this world-renowned village was held on July 29th. The number of exhibits was over four hundred, and all of them of first-class quality. There was keen competition in the table decorations both for garden and wild flowers, some of them being exceedingly well arranged. Tomatoes formed a strong class, and there were some excellent fruits exhibited. The principal exhibitors were Messrs. Geo. Williams, Mole, Webber and Wolfe. Mr. W. Matthews, of Carisbrooke Cemetery, staged a group, not for competition, which consisted of some well-grown tuberous Begonias and Fuchsias; and they well merited the Isle of Wight Horticultural Improvement Association's certificate which they were awarded.

Northwood.

This horticultural society's exhibition unfortunately clashed with Carisbrooke, but nevertheless the Show was well attended and the exhibits were fairly good. The principal exhibitors were Messrs. Young, Philips, Prince, Bull and Philpot. Many other shows are to be held in the Island during August, but the dates unfortunately again clash in several cases.—S. H.

Clematis Jackmanni at Warwick Castle.—On a recent visit to this magnificent old baronial residence of the Earl of Warwick, I was much struck with the extreme beauty of some beds of these gorgeous and effective plants—one in particular, being oblong in shape and some 12 feet in length. The Clematises were rambling at will over an iron trellis erected in convex form, but now entirely hidden from view by the profusion of purple flowers. The bed in question was edged with Dactylis elegantissima, the whole producing a charming effect. Mr. H. Dunkin informed me that they delight in a deep rich soil, the beds being watered occasionally in hot dry weather with alternate applications of clean water with liquid manure. No other attention is required (besides regulating the growths) until November, when the Clematises are pruned back, and the surface of the beds receive a liberal dressing of good manure, which is forked in about the month of February following. Many other parts of the delightful and extensive grounds contained plants of the Jackmanni type, which have been planted by Mr. Dunkin, some scrambling over ruins and others climbing up rough larch poles in conjunction with the Crimson Rambler Rose in the wild garden, the whole producing a most charming effect.—H. T. M.

Roses Maréchal Niel and Medea.

Now that the great rush of Roses is over we may, perhaps, give a few words to varieties which have once more proved the best and most stable in what has been far from an ideal Rose season. Mrs. John Laing, A. K. Williams, and others never fail us, nor do such grand Teas as Innocente Pirola, Catherine Mermet, The Bride, and Souvenir de S. A. Prince, no matter what the season may be; and it certainly seems that we shall be able to say the same of Mrs. W. J. Grant, Muriel Grahame, Mrs. R. G. Sharman Crawford, and Medea. Medea has been especially good, and the magnificent examples I have seen in stands from various parts of the country are ample proof of its general usefulness. Although not a climber, or with quite so sweet a scent as Maréchal Niel, I venture to say it is more perpetual in blooming. I would be the last to say a word against an old favourite, but at the same time we must not forget a new friend, and in Medea we have the best of dwarf, free growing, and blooming yellows, of a deep lemon shade. I note that the N.R.S. Catalogue Committee remarks upon it as requiring a warm and dry season; but do not all, even Maréchal Niel, from the Teas and Noisettes need the same? Like "W. R. Raillem," I have found Maréchal Niel a good late summer and autumnal bloomer upon old standards, but Medea has the same invaluable habit as Marie Van Houtte and a few more—viz., flowering from first to last, and producing successional crops with great rapidity. "W. R. Raillem," many of us know, can and does grow Teas second to none, and although I do not for a moment imagine him to be disparaging Medea, I fear some readers would be inclined to take his recent notes as implying such.

Medea has been grandly shown at the Temple for several years; it was the best pure lemon yellow Tea at Portsmouth and the Crystal Palace, and very few winning stands of Teas or Noisettes during this season have been minus an example of Medea. Comparatively speaking it is a new Rose, and is certainly the best and one of the most lasting yellows we have, if we except the deeper shades of Maréchal Niel and Perle des Jardins.—A. Piper.

I cannot agree with your correspondent "W. R. Raillem" that the Maréchal Niel Rose is "thoroughly perpetual in the open ground." No good gardener would ever think of planting it as a perpetual flowering Rose. Over the last twenty years I have taken part in the cultivation of thousands of this beautiful variety, and however "intelligently" pruned should never expect to get more than a single crop of flowers from it.

Although of smaller size and paler in colour Medea is thoroughly perpetual, and rarely does it produce a shoot in summer or autumn—from June to November—that is not crowned with flowers. If Maréchal Niel is so perpetual as "W. R. Railem" proclaims it to be, how is it that so few specimens are found at the summer exhibitions? for surely such a grand Rose would add lustre to any box. Some few of our largest market establishments for cut Roses have discarded this variety, mainly owing to its non-perpetual character.

Not only is Medea thoroughly perpetual, but it is one of the most exquisitely formed Roses I know of, reminding one in a marked degree of the superb, but shy-blooming, Cloth of Gold.—Walter Easlea. *Waltham Cross.*

I am quite at a loss to understand how anyone can institute a comparison between these two Roses. The one is the acme of perfection as far as colour is concerned, and the other a light lemon coloured Rose. In habit, too, they are entirely distinct. The Maréchal is a strong growing Noisette, sending out shoots from 10 to 12 feet long, or even more; Medea is a vigorous Tea, but of upright growth, and requires a warm, dry season to develop it. I should as soon think of comparing it with Maréchal Niel as I should Madame Hoste or Francisca Kruger, or any other of the lighter coloured yellow Roses of the Tea class.

Another question which seems to have been evoked by this discussion is whether Maréchal Niel can be called really a garden Rose. As regards hardiness, I think it might be well entitled to this character. I have seen it flourishing all through the southern counties, standing with some slight protection such as is generally given to Teas our most severe winters; but there is one defect about it which must ever be a bar to its being considered desirable for this purpose—namely, the flowers all hang down their heads, and the consequence is, that when it is trained against the wall you see nothing but the outside petals of the flower, which is generally discoloured. We have had two or three plants of it on some of our cottages here, but they were a failure. The plants grew well and flowered freely, but when looked at from a slight distance the plant looked as if it were covered with dead flowers; and, of course, the same holds when it is grown as a standard or half-standard.

I recollect, too, an enthusiastic Rose grower with whom it was so great a favourite that he had a large bed on his lawn planted with it. The Roses grew most vigorously, and were pegged down, but he was so disgusted with the complete failure of the appearance of the bed that he grubbed up the plants before the next season. The place for the Maréchal is unquestionably the roof of the greenhouse, where its rich golden goblets hang down and display their full beauty. No one who has seen a good plant of it in this position will ever wish to place it in any other.

It is certainly somewhat curious that although this Rose appeared in 1864 that nothing comparable to it has appeared in the thirty-three years that have elapsed since then. If one could obtain a Rose of the same colour with the upright growth of the Cloth of Gold it would be indeed a grand acquisition. Climbing Perle des Jardins has in the same way been compared by others to Maréchal Niel; but like the flower from which it sported now nearly twenty-five years ago in America, it is very uncertain in form and apt to come cleft; this, of course, detracts from its appearance and value, so Pradel's Rose still stands *facile princeps* in its class—and he would be a fortunate man who obtained a flower which would put it into the background. We know that the Maréchal is not long lived, although I have had a plant of it in my small house for fifteen years or more; but it is showing signs of giving way, and instead of the hundreds of blooms I used to have on it, I have only had a few dozen this year, having had to cut away a good part of the tree last autumn, and I am afraid the remainder will follow this year.—D., *Deal.*

Seasonable Work.

Just because the bulk of our Roses are past, we must not allow the slightest neglect in the Rose garden. Budding must be finished, stale flowers cut off, summer pruning practised among climbers and pegged-down Roses of the Hybrid Perpetual class; mulchings should be applied after a good watering where rains have not visited, and general attention given in all branches. It will be particularly helpful to give a thorough soaking of weak liquid manure to plants against walls. These absorb so much moisture in themselves that no shower does much good unless driving direct upon the wall, and our plants are more often than not carrying an extra amount of growth and confined to a narrow border. —A. P.

ROYAL HORTICULTURAL SOCIETY.

Drill Hall—August 10th.

The exhibits at the Drill Hall on this date were not very numerous but the quality was high. Herbaceous flowers were the most conspicuous, but Apples and Orchids were splendidly staged though only in small numbers.

Fruit Committee.—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, T. F. Rivers, J. H. Veitch, A. F. Barron, G. Reynolds, J. Smith, F. Q. Lane, H. Balderson, G. Wythes, T. Farr, A. Dean, and J. Wright.

Messrs. W. Fell & Co., Hexham, sent fruits of the Logan Berry, the result of a cross between the Raspberry and Black Currant, effected in America. The habit of growth, and to a less extent the character of the fruit, resembles the Raspberry. An award of merit has been previously granted for the Logan Berry, exhibited by Mr. Bunyard.

Gooseberry *Golden Gem*, a seedling, the result of a cross between Antagonist and Whitesmith, sent by Messrs. James Veitch & Sons, was at once adjudged an award of merit. The fruits are of good size, clear amber, smooth, and of excellent flavour. The variety is said to be a free upright grower.

Mr. J. Moody, gardener to F. F. Blayden, Esq., Sultan House, Sutton-on-Hull, sent a new Tomato, of medium size, with a distinct nipple. To be tried at Chiswick. Mr. Wadds, Cliveden, Maidenhead, sent a bunch of Wilson Junior Blackberry, fine fruits; also bearing stems of the Kittatiny, smaller fruits, but far better in quality—indeed, very good indeed. It is stated they were grown in strong moist soil. An award of merit was granted for the Kittatiny.

Mr. W. W. Smythe, The Gardens, Basing Park, sent bearing plants of Kidney Beans, the result of crossing the Dwarf Bean and Scarlet Runner. The stronger of these plants, named Goliath, was bearing fifty handsome pods, and the variety was recommended to be tried at Chiswick. Mr. George Kelf, gardener to Mrs. Abbot, South Villa, sent a box of Royal George Peach, grown within two miles of Charing Cross. They would be entitled to be described as grand if they had been grown under the most favourable conditions in the country, and would have won a first prize at almost any show. A cultural commendation was unanimously awarded.

Messrs. G. Bunyard & Co. sent thirty-six dishes of chiefly Apples, though including Apricots, Peaches, and Pears. The Apples were remarkably fine, though indications were not wanting of some of them at least having had the assistance of glass; but be that as it may, the exhibit was highly meritorious, and a silver Knightian medal was unanimously awarded. Mr. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, was granted a silver Banksian medal for a collection of fruit.

Floral Committee.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, C. T. Druery, H. B. May, R. Dean, F. T. Fitt, O. Thomas, H. Turner, H. J. Jones, C. E. Pearson, J. D. Pawle, J. Walker, W. Bain, R. M. Hogg, J. Fraser, and J. Jennings.

Messrs. J. Veitch & Sons, Ltd., Chelsea, staged a large collection of hardy annuals. The number of kinds was considerable, and the colours had been placed so as to produce the best possible effect. There were Lavateras, Sweet Sultans, Calliopsis, Godetias, Sunflowers, Marigolds, Clarkias, Phloxes, Verbenas, Larkspurs, Asters, Stocks, Bartonia, Calendulas, Cornflowers, and many others. This was somewhat of a change from the perennials that have so constantly been shown. The

same firm sent also hardy sbrubs, including Colutea arborescens purpurea, Hydrangea quercifolia, Ptelia trifoliata, and others.

Mr. Bain, gardener to Sir Trevor Lawrence, Bart, Burford Lodge, Dorking, exhibited a beautiful collection of Cannas and Gladioli, while Messrs. Dobbie & Co., Rothesay, staged handsome orange and lemon African Marigolds. Mr. M. Prichard, Christchurch, Hants, exhibited a collection of herbaceous flowers, comprising Tritomas, Rudbeckias, Montbretias, Phloxes, Heliopsis, Eryngiums, and Liliums. Messrs. R. Wallace & Co., Colcbester, sent superb Liliums, amongst which varieties of lancifolium and auratum were conspicuous. Gladioli also came from this source.

Delphiniums and Pbloxes were splendidly staged by Messrs. Barr and Son, King Street. Covent Garden, as were Gladioli and other hardy flowers. Messrs. A. W. Young & Co., Stevenage, sent Gladioli, Gloxinias, Carnations, and Pelargoniums. Messrs. Kelway & Son, Langport, sent spikes of Gladioli, formally laid on green baize-covered boards, which much detracted from tbeir beauty. Gaillardias also came from Langport.

Tbe Cactus Dablias sent by Mr. S. Mortimer, Rowledge, Farnham, were superb. The flowers were of good size and form and splendidly coloured. Mr. Mortimer's Sbow and Fancy Dahlias were also magnificent. In each section many of the newest varieties were staged. Mr. J. Walker, Thame, staged fine collections of Sbow, Fancy and Cactus Dahlias comprising many well-known varieties. Messrs. J. Cheal and Sons, Crawley, exhibited Cactus, Pompon and single Dahlias.

Orchid Committee.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, H. M. Pollett, F Sander, J. G. Fowler, T. Statter, W. H. Protheroe, H. J. Chapman, W. H. Wbite, J. Jacques, E. Hill. C. Winn, W. Cobb, S. Courtauld, and A. H. Smee.

Messrs. F. Sander & Co., St. Albans, sent a few Orchids, comprising Sobralias and Odontoglossums. Mr. W. H. Wbite, Orchid grower to Sir Trevor Lawrence, Bart., staged Platyclinus filiformis, Eulophia guineënsis, Masdevallia refracta purpurata and Nanodes Mathewsi, while Messrs. J. Veitch & Sons, Ltd., also exbibited a few Orchids. Of these, Odontoglossum Pescatorei Harrisianum was the most conspicuous. Mr. W. A. Young, Orchid grower to Sir F. Wigan, East Sheen, sent a few Orchid flowers.

Certificates and Awards of Merit.

Calceolaria alba (J.T. Bennett Poë).—The fine foliage and pure white flowers have a very pleasing appearance. Tbe plant is about 18 inches high (first-class certificate).

Crinum Powelli album (W. Bain).—A beautiful pure white form of the type (first-class certificate).

Dahlia Daffodil (J. Stredwick).—A delicate primrose Cactus variety of much beauty (award of merit).

Dahlia Miss Agnes Box (J. Stredwick) —A handsome Cactus Dahlia. The colour is glowing crimson (award of merit).

Gladiolus Countess Amy (Kelway & Son).—A lovely variety. The colour is soft rosy purple with a wbite throat (award of merit).

Gladiolus Mike Lambourne (Kelway & Son).—Rich, deep, velvety crimson is tbe colour of this variety. The flowers are of fine shape (award of merit).

Gladiolus Countess of Leieester (Kelway & Son).—A large flower. The ground colour is wbite with rose and purple markings (award of merit).

Hollyhock Leander (Webb & Brand) —A double variety of splendid form. The colour is very pale apricot (award of merit).

Lælio-Cattleya elegans Schröderiana (E. Asbworth).—A deeply coloured variety, with flowers of beautiful shape (award of merit).

Nymphea Marliacea flammosa (J. T. Bennett Poë).—A superb variety; the colour is deep blood red (first-class certificate).

Odontoglossum Peseatorei Harrisianum (J. Veitch & Sons, Ltd.).—A chaste variety. Tbe white petals are spotted with purple, as are the delicately flusbed sepals (award of merit).

Phlox Eugène Danzanvilliers (Kelway & Son).—A pale lilac variety of great beauty (award of merit).

Rudbeckia laeinata fl.-pl. Golden Glow (M. Prichard) —A handsome double yellow flowered variety that should become popular (award of merit).

Verbena Tresserve (J. T. Bennett-Poë).—A beautiful Verbena. The colour is rich rose (award of merit).

CHISWICK.—August 5th.

There was an unusually large attendance of members of the Committee at tbis meeting, including Mr. P. Crowley (Chairman), the Rev. W. Wilks (Secretary), and Messrs. Balderson, J. Smitb, W. Pope, G. Wythes, A. H. Pearson, J. Willard, A. F. Barron, A. Dean, G. W. Cummins, G. Bunyard, W. Farr, J. Cheal, G. Reynolds, W. Bates, and T. F. Rivers.

Early and second early Potatoes were first examined, roots of forty varieties, old and new, being lifted. None displayed any remarkable features, indeed as Potatoes now go were generally commonplace. Samples of seven that seemed to be the most satisfactory were selected for cooking, and of these only one, Sutton's Harbinger, an early flattish white round, was acceptable, getting an award of merit. Generally the tubers were unripe: Asbleafs, of which several were grown, were small and unsatisfactory. Very little disease was in evidence, but no doubt should heavy rains come, it will be found in the Chiswick trials, as the soil is so very porous. Some of those lifted will have to be seen again.

A couple of Vegetable Marrows from Constantinople were also seen, one a small white round, not nearly so good as Pen-y-byd, and the other a half long white of no value as compared with our own varieties. In these, as in Potatoes, it is very evident something really remarkable is needed to justify awards of high nature, average quality now being so good. The attention of the Committee was also drawn to numerous neat plants, some 12 inches in height, of a variety of Aubergine, the seed of wbich was sent by Dr. Bonavia as a Marrow Aubergine. The fruits closely resembled tbose of the old purple Egg Plant, rather long in form. The plant had been well grown. No award was made.

INULA GLANDULOSA.

This is a general favourite amongst the stronger growing herbaceous plants suitable for our trying seasons, and yet it is remarkable how seldom we see it as it ought to be. We have been told it was difficult to cultivate, but this we believe to be more a question of position than any fastidiousness on the part of the plant itself. Where the soil is light, sandy, and consequently very hot and dry during summer, Inula glandulosa will require a perfectly shady spot; indeed, the plant is always more robust and free-flowering if planted on a north exposure, where the sun's influence is hardly ever felt. In localities, however, where the soil is stiff and clayey it may be best to plant in full exposure, the main essential being a cool medium for the roots.

It increases very rapidly by offsets, by which means it may be propagated to almost any extent, lifting and dividing the plants in autumn, firming the soil well about the roots when replanting. The accompanying woodcut (fig. 22) gives a good idea of the size of the flowers, the numerous ray florets being cut up into narrow strips, deep orange-coloured, and surrounded by a peculiar brown hairy involucre. As a border plant it is amongst the finest for summer display, the blooms lasting a considerable time in perfection. It is a native of the Caucasus.—M.

HORTICULTURAL SHOWS.

ACOCK'S GREEN.—July 3rd and 4th.

The seventh annual Show and Fête of the Acock's Green and District Society was held on the above dates in a large and suitable field at Acock's Green. This comparatively young Society and its annual Show continue to increase both in popular estimation and extent of tbe exhibition, and in proof of the latter it may be stated tbat the number of entries on the recent occasion was the largest yet experienced, namely 1257, as compared with 1111 last year.

The most attractive feature was undoubtedly the collection of groups of miscellaneous plants, arranged for effect, amongst which the first-prize exhibit, arranged by Mr. Macdonald, gardener to G. H. Kenrick, Esq., Wbetstone, Edgbaston, excited universal admiration. In form it was a departure. The space was not to exceed 18 feet by 9 feet. The effective and gracefully arranged background was composed of a tall plant of Cocos formosum, and this was supported on either hand by Arecas, with three Humeas and slender richly coloured Crotons. The centrepiece was constructed of corktree bark. At each of the two front corners was a bark-constructed mound, containing an elegant Palm, draped with creeping plants and graceful Crotons. The front centrepiece was composed of Orchids, while the centre portion of the group formed a dell, tastefully clothed with Ferns, ornamental foliaged plants, and dwarf Ixoras. Altogether the effect was charming. Mr. E. J. Mustin, gardener to A. F. Bird, Esq., Acock's Green, was second; and Mr. A. Cryer, gardener to J. A. Kenrick, Esq., Edgbaston, third. Mr. L. Fewkes, gardener to T. Clayton, Esq., was awarded an extra prize for a meritorious group.

Specimen stove and greenhouse plants were fairly represented. In the class for six plants Mr. L. Fewkes was accorded the first prize, his best specimens being Croton Queen Victoria, Clerodendron Balfouri, and Ixora Dixiana. The second position fell to Mr. Macdonald, and the third to Mr. A. Cryer. Exotic Ferns formed a considerable and refreshing feature amidst the large display of floral colouration, and the first prize was accorded to Mr. L. Fewkes for a collection of six fine and healthy plants; the second and third positions being placed to the credit of Mr. E. J. Mustin and Mr. Macdonald respectively. Large Palms helped to lend grace, Mr. L. Fewkes again coming to the fore, followed by Mr. Macdonald and Mr. Thos. Kemp, gardener to G. E. Wright, Esq. Begonias were never better represented at Acock's Green than in the present show. Mr. W. S. Eborall, gardener to Samuel Issett, Esq., took the first prize for six plants, closely followed by Mr. Macdonald. Mr. Eborall also contribnted a meritorious group of single and double varieties, raised by himself from seed. The collection was worthily awarded an extra prize.

A notable feature was a fine array of Gloxinias, and for eight plants, Mr. R. Keeling, gardener to H. Pinnell, Esq., was easily first. Mr. H. Turner, gardener to W. G. Holder, Esq., took the second prize. Zonal Pelargoniums are also always well shown here, and Mr. J. Freeman, gardener to Zaccheus Walker, Esq., was awarded first honours for a fine group of six plants; the second and third prizes being secured by Mr. R. Llewellin and Mr. W. S. Eborall, respectively. The cut flower classes were fine, and most effectively arranged. For a collection of hardy herbaceous or perennial flowers Mr. Walter B. Child was first, and Mr.

John Freeman, second. The tropical temperature which prevailed during the two days of the exhibition quickly placed such as Roses, Dahlias (single), and other cut flowers, including bouquets, *hors de combat*. Carnations and Picotees withstood the ordeal very well, as also did the Sweet Peas. Roses were sparsely shown, and Messrs Perkins & Sons, Coventry, were awarded the first prizes for twenty-four and twelve blooms respectively for medium specimens. Carnations and Picotees were also a small class. For twelve blooms Mr. H. G. Owen was placed first, and Mr. Macdonald, second. For twelve Cactus Dahlias the first prize was taken by Mr. Thos. Perry, gardener to A. H. Foster, Esq., and the second fell to Mr. F. C. Brooks, gardener to F. Ryland, Esq.

The prizes for hardy annuals were accorded to Mr. E. Stukely and Mr. W. B. Child respectively. Stocks were abundantly shown. For twelve in pots the first prize was accorded to Mr. Thos. Needham, gardener to Mrs. Layton, Oakfield, and the second to Mr. Walter Holloway, gardener to A. Waterhouse, Esq. Perennial Phloxes were well shown by Councillor W. Waters and Mr. A. H. Foster. Very fine Gaillardias came from Mr. W. Dodd, gardener to H. H. Hartshorne, Esq., Councillor W. Waters, and others. Sweet Peas were extensively shown, the chief exhibitors of which were Mr. E. Stukely and Mr. John Stanley.

Mr. W. Sydenham, Tamworth, contributed an excellent display of Violas (not for competition) staged for effect. The collection contained many of the best and newest varieties extant. Messrs. Kelway & Son, Langport, were awarded a first-class certificate of merit for a fine display of Gladioli. Messrs. Thomson & Sons, Birmingham, exhibited pot plants and collections of Carnations and Picotees, for which a silver medal was awarded. Messrs. Pope & Son sent Cactus Dahlias.

Fruit was very well shown, Mr. J. May, gardener to G. Edmondson, Esq., secured the first prize for a fine collection of Grapes, Peaches, Cherries, Plums, and Apricots; the second prize going to Mr. Thomas Kemp, gardener to G. E. Wright, Esq. For two bunches of black Grapes Mr. H. Dix, gardener to A. Lovekin, Esq., was awarded first; and Mr. T. O. Bagg, gardener to W. E. Perks, Esq, second. For two bunches of white Grapes Mr. J. May was awarded the first prize for excellent Muscat of Alexandria; the second prize going to Mr. H. Dix.

Vegetables were, as usual, numerously and well shown in all the classes, and the liberal prizes offered by Messrs. Sydenham, Thomson and Sons, Webb & Sons, and others were keenly contested for. Praise must be accorded to Mr. Walter B. Child (the energetic Secretary) and his colleagues for the very efficient arrangements.

THE MIDLAND CARNATION AND PICOTEE.

AUGUST 5TH AND 6TH.

THE seventh annual Show of the Midland Carnation and Picotee Society was held at the Botanical Gardens, Edgbaston, as usual. In point of extent the exhibition was undoubtedly the largest yet held, the number of entries being seventy-three. The heat was almost tropical on the first day. The quality of the blooms was a distinct advance over previous occasions. Sweet Peas were a feature, while collections of herbaceous flowers, Begonias, miscellaneous plants, and Ferns lent much effect to the scene. A notable feature was the competition for the "Charles Turner Memorial," value 10 guineas, to be competed for by amateurs, to be won two years in succession, or three times in all. It was taken by Mr. A. W. Jones (57 points), and the handsome trophy now becomes his own property. The Society's "challenge cup," value 10 guineas, was won by Mr. Robert Sydenham (74 points), and it now becomes his own property. This gentleman announced that as he had won the cup outright he would next year present another one to the Society, and not to compete for it himself. The following are among the chief awards:—

For twelve flakes or bizarres Mr. J. Edwards, Manchester, was awarded the first prize for grand blooms of J. S. Hedderly, James Douglas, and Robert Houlgrave, Sportsman, Mrs. Rowan, Sarah Payne, Master Fred, Ellis Crossley, Lord Salisbury, Mrs. Gunn, Joseph Lakin, and Ed. Rowan; and Mr. Tom Lord was second. For six ditto, Mr. C. F. Thurstan, Wolverhampton, secured first honours with a good stand, the second prize falling to Mr. A. R. Brown, Handsworth.

For twelve white-ground Picotees Mr. Robert Sydenham was accorded the premier position for a superior board, containing Ganymede (very fine), Mrs. Payne, Clio, Jessie, Pride of Leyton, Muriel, Esther, Favourite, Thos Williams, Little Phil, Somerhill, and Scarlet Queen; the second prize going to Mr. T. Lord, and the third and fourth to Messrs. Thomson & Son, Birmingham, and Mr. A. R. Brown respectively. For six ditto, Mr. A. W. Jones, Handsworth, claimed the first prize; the second prize went to Mr. F. W. Goodfellow, Walsall.

For twelve yellow ground or Fancy Carnations or Picotees, dissimilar, Mr. A. W. Jones was awarded first honours for a grand exhibit, consisting of Voltaire (very fine), The Gift, Ladas, Golden Eagle, Xerxes, Mrs. Robert Sydenham, Harlequin, Mrs. Nigel, The Dey, Cardinal Wolsey, and two others; whilst Mr. R. Sydenham was a close second with fine blooms. The third prize was taken by Mr. A. R. Brown. For six ditto prizes fell to Messrs. C. F. Thurstan, C. Cartwright, Sellyoak, and R. Sydenham in the order named. For six yellow ground Picotees the first prize was secured by Mr. A. W. Jones, Messrs. Thomson & Co. being second, and Mr. A. R. Brown third.

For twelve selfs, dissimilar, Mr. A. R. Brown was victorious with Little John (fine), Britannia, Mrs. E. Hambro, Her Grace, Hayes Scarlet, Germania, Royal Purple, Nabob, Topsy, Lady Mary Currie, Bendigo, and Braw Lass; Mr. R. Sydenham coming an excellent second, and Messrs. Thomson & Co. third. For six selfs Mr. A. W. Jones was first, Mr. C. F. Thurstan second position, and Mr. J. Walker, Thame, third.

In the class for twelve selfs, Fancy or yellow grounds, to be staged in a space not exceeding 20 inches square, to be dressed as little as possible, Carnation foliage and buds allowed, the first prize was awarded to Messrs. Thomson & Co., the second to Mr. A. W. Jones, and the third to Mr. Blick, gardener to Martin R. Smith, Esq. For six ditto, the first prize was placed to the credit of Mr. Geo. Chaundy, Oxford, and the second to Mr. R. C. Cartwright. For six flakes or bizarres and six Picotees, Mr. R. Sydenham and Mr. J. Edwards were first and second respectively. For three ditto, the first position was accorded to Mr. D. Walker, and the second to Mr. W. Bellamy, Harborne. For six Carnations or Picotees (amateurs), Mr. G. F. Spittle, Edgbaston, was placed first, Mr. H. Hunter, Walsall, second, and Mr. F. Steele third.

FIG. 22.—INULA GLANDULOSA.

In the class for single bloom scarlet bizarres, Mr. R. Sydenham was first with a splendid bloom of Robert Lord, and Messrs. Thomson & Co. second with a fine example of Robert Houlgrave. Crimson Bizarre.—Mr. J. Edwards was first and second with fine blooms of J. S. Hedderly. Pink and Purple Bizarres.—Mr. A. R. Brown occupied the premier position with Sarah Payne, and Mr. R. Sydenham the second. Scarlet Flakes.—The first prize was secured by Mr. D. Walker for a very good edged red, the second by Mr. J. Edwards with Sportsman, and the third by Mr. R. Sydenham for the same variety. Rose Flakes.—Mr. J. Whitham secured the first prize with a new seedling and Mr. T. Lord the second, whilst Mr. Whitham was placed third. Purple Flakes.—Here Mr. R. Sydenham secured the first and second positions for fine blooms of Gordon Lewis, and Mr. A. Bellamy the third prize for a good bloom of the same variety.

Heavy Red-edged Picotees.—Mr. R. Sydenham claimed first honours for a fine bloom of Ganymede, the second by Mr. A. R. Brown, with a good Ne Plus Ultra, and Mr. C. Head was placed third with John Smith. Light Red-edged.—The first prize went to Mr. A. W. Jones for Thos. Williams, the second prize to Mr. R. Sydenham for ditto, and

the third to Mr. A. W. Jones for Mr. Gorton. Heavy Purple-edged.—The first prize was won by Mr. A R Brown for Mrs. Oppenshaw, and the second and third to Mr. R. Sydenham with Muriel. Light Purple-edged.—Mr. A. R. Brown was first and second for Pride of Leyton, and Mr. C. F. Thurston third. Heavy Rose-edged.—The first prize fell to Mr. A. W. Jones for Madeline, the second to Mr. T. Lord for Lady Louisa, and Messrs. Thomson & Co. were third for Little Phil. Heavy Scarlet-edged.—Mr. C. Head was placed first with Mrs. Sharp, Mr. R. Sydenham second with Scarlet Queen, and Mr. A. W. Jones third for Mrs. Sharp. Light Rose or Scarlet-edged.—The first prize was taken by Mr. T. Lord with Favourite, the second by Messrs. Thomson & Co., and the third by Mr. R. Sydenham with the same variety.

White or Flesh Selfs.—The first and second prizes were secured by Mr. C. F. Thurstan for good blooms of Mrs. Eric Hambro, and the third by Mr. J. Edmunds with a very good Mrs. Lee. Yellow, Buff, or Terra-cotta Selfs.—Here Mr. A. R. Brown had the first and second prizes for splendid blooms of Germania, whilst the third and fourth prizes went to Mr. C. F. Thurstan and Mr. R. Sydenham respectively with the same variety. Pink, Rose, or Scarlet Selfs.—In this class Mr. T. Low took the first three prizes with fine blooms of Mr. T. Helliwell, a seedling, and another example of the first named. Dark Selfs.—The first prize fell to Mr. A. R. Brown for an excellent Topsy, the second to Mr. J. Brocklebank with Negress, and the third to Messrs. Thomson & Co. for Pilgrim.

Yellow-ground Picotees.—Here Mr. R. Sydenham claimed first honours for a grand bloom of Mrs. R. Sydenham, the second position falling to Mr. F. W. Goodfellow, and the third to Mr. Sydenham with the same variety. Fancy Carnations or Picotees.—Mr. A. W. Jones secured the first and second prizes with fine blooms of Voltaire, and Mr. R. Sydenham the third for a good example of Monarch. Mr. A. W. Jones took the first and second prizes for Fancy Carnations, and border Carnations and Picotees were well exhibited by Messrs G. Lindop, Langport; J. Walker, Thame; H. W. Weguelin, Torquay; W. Barsby, Leicester; C. Blick, and Thomson & Co.

For six Carnations in pots Messrs. Thomson & Co. and Mr. R. Sydenham were placed first and second respectively, being the only exhibitors. For shower bouquets the respective winners were Mr. C. Blick, Mr. W. F. Gunn, Olton, and Miss B. Mayell, Acock's Green. Sprays were also very good, the first prize falling to Mr. C. Blick, the second to Messrs. R. W. Proctor & Son, Chesterfield, and the third to Messrs. Thomson & Co. Three buttonholes.—Mr. R Sydenham took the first, and Mrs. Lovatt, Newport, Salop, the second prizes, with Mr. R. C. Cartwright in the third place. For table decorations the first prize was worthily accorded to Miss B. Mayell, second to Miss Swinden, Birmingham, and the third to Miss Kemp, Edgbaston, and an extra prize to Mrs. Lovatt.

The following awards were made for non-competitive exhibits:—Silver-gilt medal to Mr. J. H. White, Worcester, for collection of herbaceous plants; silver medals to Messrs. Hewitt & Co., herbaceous and other plants; Mr. B. R. Davis, Yeovil, for double Begonias; Mr. H. Eckford, for Sweet Peas; and Messrs. W. & J. Birkenhead, Sale, for Ferns; bronze medal to Mr. W. F. Gunn, for hardy border flowers. First-class certificates were awarded to Mr. J. Whitham for Picotee Mary Ann; to Mr. W. Kenyon for Picotee Harry Kenyon; to Mr. T. Lord for Picotee Grace Ward; and to Mr. Tom Lord for a rose-flake Carnation, Mr. Tom Lord.

HARBORNE.

Held in the picturesquely situated vicarage field, than which it would be difficult to find a more appropriate site, the Show was one of the best ever held by the Society since its inception thirty-six years ago. The centre of attraction were the groups of plants arranged for effect, of which there were five. The first prize was awarded to Mr. S. Gibbs, gardener to J. B. Manley, Esq., Harborne, the plants consisting principally of Palms, richly coloured Crotons, Dracænas, Liliums, Streptocarpus, Gloxinias, Ixoras, with, in the centre, a well-flowered plant of Romneya Coulteri (Californian Poppy). Second honours fell to Mr. Oliver Brasier, gardener to Lady Martineau, Edgbaston, the group having a more imposing effect at a distance by virtue of the artistic disposal of taller elegant plants and the greater profusion of those with white flowers, such as Lilies and Francoas. The third prize fell to Mr. A. Cryer, gardener to J. A. Kendrick, Esq., Edgbaston, for a very good group; and the fourth prize to Mr. Batchelor, gardener to Mrs. Armfield, Edgbaston.

The gigantic specimen plants which have upon previous occasions characterised the Harborne shows had an imposing effect. Mr. Maldrem, gardener to Geo. Cadbury, Esq., Northfield, as on the last occasion, took first honours with grand specimens of Crotons, Palms, Statice profusa, Stephanotis floribunda, Dipladenia amabilis, and Allamanda Hendersoni. Mr. Brasier was a close second with also very fine and healthy specimens, similar in variety to the former. Fuchsias (six varieties)—which have for so many years been a feature here—were exhibited in full size and form by Mr. S. Gibbs, to whom the first prize was worthily accorded. For three varieties the successful contestants were Mr. Maldrem and Mr. Brasier. For six foliage plants for table decoration Mr. Brasier and Mr. Cryer were awarded the first and second prizes. Exotic Ferns were exceedingly well shown by Mr. Maldrem, Mr. Batchelor, and Mr. Brasier. For six varieties of stove or greenhouse cut flowers Messrs. Maldrem and Brasier were respectively to the fore. Roses, owing to the lateness and climatic conditions of the season, were not a strong class. The first prize fell to Mr. W. Charlton, the second to Mr. Halse, and the third to Mr. Geo. Newell, gardener to C. B. Cave, Esq., Harborne.

Fruit and vegetables were very well represented, the black Grapes staged by Mr. S. Gibbs, Mr. A. H. Griffiths, Edgbaston, and Mrs. Armfield were creditable examples; whilst white Grapes, shown by Mr. Griffiths and Mr. Brasier, were meritorious. Peaches were unusually good. For a dish of nine fruits Mr. Griffiths was placed first, and Mr. Cooper (gardener, Mr. C. H. Field), Edgbaston, with a dish of highly coloured Hale's Early, was a very close second. Mr. A. H. Griffiths was worthily awarded the first prize for a collection of six dishes of fruit. There was keen competition in the classes for collections of vegetables offered by several well-known firms, including Messrs. Sutton & Sons, Reading, Messrs. Webb & Sons, Wordsley, Messrs. Thomson, and Mr. Robert Sydenham. The produce was excellent.

A meed of praise must also be accorded to Mr. C. R. Bick, gardener to Walter Chamberlain, Esq., Harborne Hall, for a miscellaneous collection of exhibits including a beautiful dish of Tomatoes, a collection of large Gooseberries, Carnations and single Dahlias, for which special certificates were worthily bestowed by the judges. Certificates of merit were also awarded to Mr. W. Charlton for a splendid collection of hardy perennial flowers, and to Mr. Geo. Newell for Carnations and Picotees.

THE BEDDINGTON, CARSHALTON, AND WALLINGTON HORTICULTURAL SOCIETY.

This Surrey Society, which A. H. Smee, Esq., C.C., has done so much to make prosperous, and of which his gardener, Mr. G. W. Cummins, is the efficient Honorary Secretary, has made remarkable progress during recent years. The annual show held in Beddington Park, near Croydon, on Bank Holiday, is said to have been attended by 10,000 people. The chief interest usually centres in the class for a collection of nine kinds of vegetables, in which the £5 provided is divided among the six best exhibitors proportionately with the points of merit awarded to their several products. In the present instance the result was as follows:—

Collection of Vegetables.

1st,	Mr. H. Stevens	59	points ...	value	19s. 8d.
2nd,	Mr. H. Shoebridge ...	56	,, ...	,,	18s. 8d.
3rd,	Mr. Harvey Hopkins ...	51½	,, ...	,,	17s. 2d.
4th,	Mr. J. Cupps	48½	,, ...	,,	16s. 2d.
5th,	Mr. O. McRae	46½	,, ...	,,	15s. 5d.
6th,	Mr. W. Henn	39	,, ...	,,	12s. 11d.
					£5 0 0

This system originated at Carshalton some years ago, and is considered so equitable that there is no desire to alter it. The competition is open to amateurs, gardeners, and allotment holders. If the sum had been divided into three prizes of £3, £2, and £1 the three first named exhibitors would have secured the whole of it with an aggregate of 166½ points, while the three others would have received nothing for 134 points, a difference of only 32½ points. But valuing in this competition a point at 4d., each of the six exhibitors had his share. The two first exhibitors are gardeners, the other four allotment holders, Mr. Harvey Hopkins being again the champion of the county with 170 marks of merit for the cultural excellence displayed in his plot.

The system of judging above indicated could not, for obvious reasons, be carried out throughout an exhibition, but one or two classes thus treated creates considerable interest among exhibitors and visitors.

In the county competition Mr. G. W. Cummins secured the chief prize for a beautiful group of plants, for which was also granted the silver medal as the most meritorious exhibit in the Show. Fruit and vegetables were admirably represented; but decorated tables, as at many shows, were weak owing to the formal stereotyped methods adopted, which characterise so many of these floral arrangements.

A conference tent was provided, and addresses given on gardening to a large and appreciative audience. The diligent Assistant Hon. Secretary, Mr. Toogood, had a severe sunstroke on the ground, from which he was removed in Mr. Smee's carriage, and was long in recovering.

KING'S NORTON.

The fourteenth annual Show of this Society was held in the charming grounds of E. G. Bellis, Esq., King's Norton, and whose gardener proved to be one of the foremost prizetakers in the exhibition tents, his leading efforts being an attractive group of miscellaneous plants arranged for effect. The second honours fell to A. H. Wiggin, Esq., whose gardener, Mr. A. Silk, must be credited with considerable taste in the arrangement of plants. The third prize was taken by Mr. J. Palmer, gardener to J. Earle, Esq., King's Norton, for an elegant composition, which but for a certain lack of colour would have occupied a higher position—perhaps the highest. Specimens of stove and greenhouse plants were creditably shown, but do not call for special notification, excepting the first prize collection of nine plants by Mr. Palmer, which included a very fine specimen of an Ixora and an Allamanda, the second prize being taken by Mr. T. Day, gardener to E. J. Thackeray, Esq. In the smaller class, Mr. D. Eaton, gardener to W. Tallis, Esq., was the most successful exhibitor, with very good examples.

Mr. Bellis and Mr. S. Moss, gardener to W. Walker, Esq., secured the prizes for Palms; Mr. Wiggins; Mr. T. Farmer, gardener to W. H. Wynn, Esq.; and Mr. T. Day for Begonias, which were very good; Mr. C. Silk and Mr. J. Palmer for Caladiums; Mr. J. Palmer and Mr. Bellis's gardener for very good Coleuses. Roses were fairly good for the season, and Mr. G. Winchester, gardener to Fred Impey, Esq., secured the first

prize; Mr. C. Silk being second. A notable feature was the display of table decorations by ladies, baskets of flowers, and epergnes, Mrs. Theodore Pritchett, Mrs. J. G. Pritchett, Miss Wolsley, and Miss Ellis distinguishing themselves in these classes.

Fruit and vegetables were well shown. The Black Hamburgh and Muscat of Alexandria Grapes, by Mr. W. Abbey, gardener to E. Chatrain, Esq., Northfield, being very creditable examples. Mr. E. Winchester was placed second with also good bunches. Mr. T. Cox, gardener to J. B. Moseley, was the most successful exhibitor in the Melon class, and Mr. T. Farmer had the best Peaches. Mr. E. Winchester, gardener to F. Impey, Esq., won first honours with an excellent collection of vegetables.

There was keen competition for the substantial prizes offered for vegetables by Messrs. Sutton & Sons; also for those by Messrs. Simpson & Sons. Messrs. Pope & Sons were accorded a silver medal for a group of plants, and Messrs. Ellis and Johnson a bronze medal for a collection of miscellaneous plants.

THE YOUNG GARDENERS' DOMAIN.

Strawberries.

Our soil is a light sandy loam, while our plants are mostly three years old. The plantations are open and sheltered on all sides, and receive due attention. The earliest fruits were gathered this year from John Ruskin. These were gathered about Jubilee day. Royal Sovereign followed three days later. At an exhibition of Scotch-grown Strawberries, under the auspices of the Scottish Horticultural Association, Mr. Dunn, Dalkeith Palace, characterising the varieties shown, stated that John Ruskin is much finer and better treated as an annual. No doubt, but with the enormous demand upon us for Strawberries we believe in quantity more than in purity of quality, especially in our restricted space. We have a number of fine young plants which gave us a fair show of fruit, but I am bound to say of no superior quality to these three years old. John Ruskin, too, has borne prodigiously. For weeks and weeks past we have had laden trusses, fruit of moderate size, though not so firm fleshed or well flavoured as we wish. Royal Sovereign, like all large Strawberries, does best on a light or medium soil. At Dalkeith Palace this variety was inferior till warm weather set in. With us it is good.

Garibaldi has a heavy crop of small sized fruit, but the flavour is next to perfection. Evidently younger plants and more liberal nourishment would aid it on our soil. During the recent rains its flavour, to my taste, never altered, while better ones became watery. Would "Pomona," or the Editor, state why the Italian hero's name is superseded by the French Countess's? Our Scotch authorities hold there is no difference between the Vicomtesse Héricart de Thury of Englishmen and the Garibaldi of Scotch growers, and prefer the simpler name. "Pomona" saves me describing Scarlet Queen; it has yielded a good crop, only it shrivelled worse after setting than the others during the early dry weather.

"British Queen," said Mr. Dunn, "is the type of Strawberry," I suppose his ideal type, and urges all to judge new varieties from and by it; whoever raises a better one must be in the circle of perfection. To this Mr. D. T. Fish gave an audible "hear, hear." It has done good service. Duke of Edinburgh is a worthy Scotch-raised Strawberry of large size, good flavour, and fine shape. I have seen it produce well on what we termed a gravelly soil. On the same soil Land o' Scot, Sir J. Paxton, and Laxton's Noble were grown and favoured; the latter was very firm fleshed. Auguste Nicaise has not large fruit with us, the appearance and flavour, however, are reciprocative. Lord Suffield with light foliage of medium strength has a poor crop and unpleasant flavour. Mr. Dunn pronounced it coarse. Lord Lyon, thick black leathery foliage, very strong and dense, with poor shrivelled trusses newly set. We have determined to give these two Lords a holiday in the "Home of Refuse!"

Soon after the fruit is gathered we mulch all with short manure, and fork this into the soil just before growth starts in spring. The soil drying speedily, we give liquid manure occasionally and frequently use the hose and spray.—A Young Scot.

[Vicomtesse Héricart de Thury is the proper name of the hardy and useful French Strawberry to which it is applied. It is the first recognised name, and priority is the determining factor in all such cases. Garibaldi, as may be seen in the late Dr. Hogg's "Fruit Manual," is a synonym.]

Cultivation of Dracænas.

Dracænas are very useful plants, both for beautifying the stove and conservatories, and for house and table decoration. A stove temperature, where they can obtain plenty of heat and moisture, is the most suitable for the coloured-leaved varieties, and a cooler temperature for the green section. Propagation may be effected by several different methods. I will first describe what I consider the most effective process for plants that have lost their bottom leaves, and have become what is termed "leggy." First, take a pot of a size according to the top of the plant that is to be propagated, and break it in half. This may be done by first giving the pot a few gentle taps with a hammer along the place required for it to break, gradually hitting harder, especially at the edges of the bottom, until it breaks. If the pots are thin and sound previous to attempting to break them an expert hand will spoil very few. The stem of the plant should then be cut upwards with a sharp knife for about 2 inches, gradually working into the centre, so as to form a tongue; and before the knife is withdrawn insert a thin piece of charcoal to keep the cut open. Insert two stakes in the pot opposite each other, and place the halves of the broken pot one on each side of the incision, fastening them securely together, and also to the stakes, with wire. Two short pieces of wood placed under the pot, one on each side of the stem, will help to keep the halves from slipping down. It will be necessary for two pairs of hands to be available at this stage, one to hold the top of the plant, to prevent it overbalancing and breaking off, whilst the other fixes the stakes.

When the halves of the pot are made secure in their position place a small quantity of charcoal in the spliced pot, and round the incision a compost of fibrous loam and peat, broken into small lumps, with a liberal addition of silver sand. When signs of roots are apparent cut the stem half way through just below the pot, and in a week or so the top may be taken off and placed in a larger sized pot.

Another method of rooting the tops is after the stem has been cut, and a piece of charcoal inserted, place some sphagnum moss round the incision, fastening it with twine or fine wire. If this is kept moist the stem will soon emit roots into it. When propagated in this way the plants when taken off are placed in small pots, and afterwards in others of a larger size. Another method of propagation is by "topping"—that is, the top of the plant is cut off, inserted in a small pot, and placed in a propagating frame.

The old stems, after the tops have been removed, may be allowed to break, and the growths, when large enough, inserted singly in small pots as cuttings; or a stem may be cut into pieces 1 or 2 inches long, and placed lengthwise in pans, giving them a light covering of soil. If these are placed in a gentle bottom heat they will soon start into growth at the joints. Dracænas may also be propagated by taking off pieces of the thick, tuberous-looking roots, and placing them in pots.

The most suitable compost for the final potting is fibrous loam and peat in equal parts broken into small lumps with a small quantity of charcoal, with silver sand and bonemeal, or any approved artificial manure added. Never allow the plants to get dry, and when the pots are filled with roots liquid manure may be given them, also an occasional top-dressing with artificial manure. During the spring and summer months syringing will be necessary, but it must be discontinued during the winter, for at this period water lodging in the axils is apt to cause the leaves to damp off. The plants also require shading from the bright sun.

Varieties.—These are numerous and vary both in height and character of growth. For tall specimens Shepherdi, Baptisi, nigro-rubra, Massangeana and amabilis rank among the best; and for decorative purposes Goldieana, terminalis, metallica, magnifica, Lindeni, Guilfoylei, Banksi, and superba. The best of the green varieties are gracilis, indivisa, i. Veitchi, australis, and stricta congesta. The pretty little D. Sanderiana, with its green and white foliage, is useful as an edging plant for groups, and for this purpose 3½-inch pots are large enough for the plants.

Enemies.—Green fly attacks the points of the young leaves and may be removed by sponging with an insecticide or fumigating. Thrips are the worst enemies the Dracæna has to contend with, and when plants are attacked with these they should be dipped or sponged with strong tobacco water.—Elveden.

HARDY FRUIT GARDEN.

Planting Strawberries.—The earliest raised plants rooted in pots or turves may now be planted permanently on suitably prepared and liberally enriched ground. The plants should be well furnished with roots, and have bold healthy crowns. Previous to planting thoroughly moisten the ball of roots. Should the weather be extremely dry each plant must be copiously watered when inserted, forming a basin round it and filling with water, after which cover in with dry soil.

Moist, dull weather is really the best time to plant, but with care in affording moisture planting may be successfully carried out in the driest time, providing the plants are strong and vigorous and the roots adhere to balls of earth. Those rooted in pots or turves fully occupy the rooting medium, and are well equipped for making a start in the fresh soil. In inserting the plants form excavations, so that the roots are not cramped. Press the soil firmly about them, and water before finally filling in. In continued dry weather water frequently until fairly established.

Soil Preparation for Later Planting.—Later plantings of Strawberries may be carried out towards the end of present month, also in September. In the meantime prepare the soil by deeply digging or bastard trenching, adding liberally some rich substantial manure. By the time the plants are ready for insertion the soil will have become consolidated, and in excellent condition for their reception. Poor light soils must be liberally supplied with manure, worked well into the surface and lower layers. Heavy retentive soils naturally require well breaking up to a good depth rather than the addition of much manure.

Some light gritty material of an opening character proves of important service by improving the mechanical condition.

Trimming Strawberry Beds.—Frequent opportunities ought to be taken to cut out superfluous runners from all plants. Those from which new stock is not being cultivated may be entirely cleared of runners. Weeds also remove. Loosen the surface where hard. Excellent plants may be found rooted, or rooting, naturally into the soil of established beds. These, if wanted, can be preserved for shortly lifting and planting in a permanent bed. Superfluous growth surrounding and overcrowding them must be carefully removed. Beds left too long after fruiting before clearing become a mass of weeds and runners difficult to remove.

Summer Thinning and Regulating Fruit Trees.—At no season of the year can a better judgment be formed of the condition of fruit trees as regards the disposal of branches than during the season when the foliage is present. Overcrowding is unmistakeably shown by the interlacing of branches and the rank growth of shoots. Through this the sun cannot properly penetrate, nor air gain access, especially to the remote parts of the trees. Numbers of trees grown in a free unrestricted form, including tall and dwarf standards and open bushes, pay for a little attention at the present time. Thinning-out and regulating the branches is important. Dispose them in the best possible manner in order that they may receive the full benefit of the summer and autumn weather.

Pruning away branches in summer does no harm to the trees. Of course, very severe treatment may result in no apparent advantage for a time. Trees neglected for years cannot be otherwise than severely dealt with in attempting renovation. When attended to annually only a limited amount will be found necessary to remove at any one time. Cut out first the crossing and interlacing branches, then the useless interior spray or wood, which is usually shaded and weakened. All the wood intended for removal cut out entirely, close to older branches, avoiding shortening.

Gooseberries.—The same principles of thinning and regulating may be extended to Gooseberry bushes. A quantity of wood is produced during the growing season which renders the bushes overcrowded. Sucker growth from the base is prevalent on some, and this ought early to be dispensed with, low-lying branches near the soil cut out and shoots growing towards the centre. This preliminary treatment being completed, then give the bushes a general thinning wherever shoots are unduly crowded.

Black Currants.—Prune out the old bearing wood, which will leave room for the young strong growths produced during the current year to develop, these alone giving the best results.

Red Currants.—The main branches of Red, also White, Currants are each simple cordons extending from the base of bushes or from near the main stem. The summer growths are freely produced from the main branches. It is not usual to thin them out, but to shorten them at the third leaf in order to plump up their buds at the base. This ought to be done now if not previously carried out. Any old worn out branches may be cut out, and the nearest strong young growths from the base allowed to take their place.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest Forced House.*—Trees started in December may be falling more or less, yet there must not be any lack of moisture at the roots, affording water and even liquid manure to weakly trees as necessary to maintain the soil in a moist but not saturated condition, excessive moisture and warm weather being apt to cause premature growth. It does not matter so much about rain, as with it the air is comparatively cool, and then has a beneficial and invigorating effect. As a safeguard against starting the blossom buds, allow such laterals as are green and unripe to remain as an outlet for any excess of sap, and they are equally effective in maintaining activity at the roots. Early forced trees, however, do not, as a rule, make strong growth, having generally a larger proportion of single fruit buds than trees grown under more favourable circumstances, triple buds not being nearly so frequent, hence in pruning it is not desirable to cut back next year's bearing wood unless of great length.

Very little pruning will be needed provided disbudding has been attended to, no more wood being trained in than is necessary to replace the bearing shoots of the current year, and to renew worn-out growths, as well as to provide for the extension of the trees. Trees that have long been subjected to early forcing seldom grow too vigorously, but not infrequently become so enfeebled as to need the removal of the weak growths, which, though plentifully furnished with blossom buds, are undesirable, from their affording much smaller fruit than is yielded by the moderately vigorous and well-ripened growths. Some trees, however, make too vigorous or long-jointed wood, pushing laterals difficult to restrain, if they do not frustrate the formation of fruit buds and interfere with an equal distribution of the sap. Any trees which grow too vigorously must be lifted, whilst those which show symptoms of weakness may have the old soil removed from amongst the roots, supplying fresh turfy loam, with about one-sixth of old mortar rubbish added. Give a good watering both to the lifted trees and to those that have had the soil renewed about the roots. These operations require to be performed as soon as the leaves are mature, and before they fall from the trees.

Succession Houses.—Cut out the shoots that have borne fruit unless required for extension, and where the growths are crowded thin the shoots. This will allow the foliage to be more readily cleansed by syringing, repeating that as necessary, it being important that the foliage be kept clean and healthy as long as possible. With free acess to light and air the buds will form perfectly, attention being given to a due supply of water at the roots. When the fruit is ripening a free circulation of air will enhance the quality, sufficient water only being given to the roots to prevent the foliage becoming limp, securing air moisture by an occasional damping of the paths and borders for the benefit of the foliage, also fruit, which in an arid atmosphere is liable to become mealy, whilst it ripens prematurely if the trees suffer from an insufficient supply of moisture in the soil. Ants in some cases are troublesome, eating into the choicest fruits. Wrapping a little cotton wool round the stems of the trees hinders their ascent, securing it with twine in the middle soaked in a saturated solution of camphor. Saucers sunk in the ground level with their edges and as near their haunts as possible, and pouring some treacle or syrup into each, attracts them from the fruit. It is a good plan to dip bits of dry sponge in treacle held tightly in the fingers, then release the pressure and get some of it into the sponge. When the ants are at these the bits of sponge can be dipped in boiling water for the destruction of the pests. Continue this for a time and there will soon be a difference.

Late Houses.—Attend to thinning and regulating the current year's growths, and if they are laid in thinner than is customary with trees in early houses the wood will have a better chance of ripening, and the leaves will assimilate more food, storing it in the bud and wood for the support of the blossoms and embryonic fruit in the coming season. Gross growths tend to the impoverishment of the weaker, appropriate an undue amount of sap, preventing an unequal distribution of the nutrition, and favour nothing but unfruitfulness and gumming. They must be stopped or removed altogether. Endeavour to secure an even balance of moderately vigorous short-jointed shoots, and to insure the wood ripening in cold districts ventilate freely in the early part of the day, allowing a good heat through the day from sun, closing in time to run up to 85° or 90°, for sun heat after evaporation has been going on for some time will not do any harm if only care is taken to admit a little air before nightfall to allow the pent up heat and moisture to escape and the gradual cooling down of the atmosphere, thereby securing rest. The early day and night ventilation tends to the solidification of the growth and its ripening. Keep the trees free from red spider by forcible syringings until the fruit gives indications of ripening. The borders must be well supplied with water or liquid manure, and be mulched about an inch thick with short, rather lumpy manure from the stables.

Vines.—*Early Houses.*—The earliest forced have the wood ripe and some of the leaves falling. Do not attempt to remove them forcibly nor cut the laterals close in, as that would probably cause the principal buds to start; therefore remove the laterals by degrees, and shorten some of the strong shoots, preserving, however, some growth, especially when the principal leaves are down, above the buds to which the Vines are to be pruned, deferring the final pruning until the early part of September. The old soil should then be removed from the surface of the border, forking some of it from amongst the roots, taking advantage of the opportunity to raise any that are deep and laying them in fresh material nearer the surface. Good calcareous loam is the most suitable, with an admixture of opening material, such as old mortar rubbish and charcoal. A little approved fertiliser is also an advantage. When the Vines are indifferent in health lifting may be carried out before the leaves fall then with a moderate watering the roots will push, especially adventitious ones, from near the collar into the new soil at once, and be in capital condition for starting when the time comes round. When lifting or renovating the border is delayed until the leaves are all down the trees do not start so freely, the break often being unsatisfactory.

Midseason Houses.—The Grapes upon the whole have been satisfactory as regards colour and bloom, and the season has favoured finish rather than size. Red spider in many cases has been very troublesome. Copious supplies of water through a light surface mulching of sweetened manure, along with fertilisers or liquid manure of a sustaining nature, with due atmospheric moisture, appear least favourable to its spread, and contribute to a satisfactory result in the crop. A good array of foliage fully exposed to light seems a delight of the Vine, as the wood is then stout, short-jointed, and the leaves thick and deep green in colour, the Grapes swell, and the buds are plumped for next year's bearing. Fire heat is often necessary to ripen midseason Grapes perfectly, but with ventilation day and night to insure a circulation of air it may often be dispensed with in warm weather. The nights, however, are now getting cold, and fire heat may be necessary, though a good rest at night aids Vines wonderfully that are carrying heavy crops of Grapes. Enough fire heat should be given to maintain the temperature at 70° to 75° by day and 60° to 65° at night, allowing 5° more for Muscats. Take care that moisture is not deposited on the berries of these during the night or in the morning for lack of early attention to ventilation, otherwise spot may be the consequence.

Late Houses.—Afford full supplies of water through a good surface mulching, sweetened horse droppings or stable litter freed of the straw answering well when not more than a couple of inches thick, continuing the supplies of nourishment until the Grapes are well advanced in colouring. Most late Grapes take a long time to perfect thoroughly, and some, particularly Mrs. Pince, even after appearing finished, are not so up to the shank. This is often a consequence of too short supplies of nourishment, and in some cases a consequence of too early stopping the supplies of food is manifest in the Grapes shrinking, as not unfrequently occurs with Muscats. All late Grapes require time. They ought now to be colouring, or advanced therein, and they must have a fair

amount of air moisture with a circulation of warm air constantly, in which they will attain fulness of berry and perfection of finish, diminishing the air moisture as the Grapes advance in colouring. Poverty of finish is the chief cause of Grapes shrivelling. Cracking results from a close atmosphere following a period of drought, or ventilating injudiciously. An arid atmosphere in the early stages of ripening renders Grapes liable to split when ripe, if, indeed, they ripen without cracking. Afford a temperature of 70° to 75° by day artificially, 80° to 90° with sun, and close sufficiently early to increase to 90° or 95°. When the sun is losing power put on enough top and bottom ventilation to insure a circulation of air, allow the temperature to gradually cool, which rests the Vines, and increase the ventilation early with the advancing temperature. The hot-water pipes should, if necessary, have a little warmth in them to prevent the night temperature falling below 65° at night. The laterals should be kept fairly well in hand, not allowing crowding, and keeping rather more foliage over black Grapes than white ones, which require more light as a rule to finish well.

PLANT HOUSES.

Erica hyemalis.—Do not crowd these too closely together, or the lower foliage will turn brown and eventually fall. If thoroughly hardened these plants are better standing on a bed of ashes outside in an open sunny position. Partially plunge the pots of the front row and the plants will afford sufficient shade to the others. Be careful they do not suffer by an insufficient supply of water. Keep the material moist on which they stand, and syringe the plants in the afternoon of dry days. Where they are protected in frames it is a good plan to raise these from the ground, so that a good circulation of air can play amongst the plants. The lights should be drawn off during the day.

Erica melanthera.—As these flower late they will now be in active growth, and should be kept in frames for some weeks. Encourage them to make their growth by closing the frame early in the afternoon. This species is benefited by this treatment, and is not liable to be attacked by mildew. Give plenty of air during the day, syringe morning and evening in dry weather, and give liberal supplies of water. If any of these plants need repotting it should be done at once. Do not disturb the old soil further than is necessary to remove the drainage; press the soil, peat, and sand firmly, and give water with caution for some time afterwards. A light shade over the frame during the hottest part of the day will prove beneficial.

Azalea amœna.—Plants that were assisted to make their growth early, and have been gradually hardened by abundance of air and exposure to light, may be stood outside. If they have been growing under Vines and Peaches thin tiffany should be arranged so as to shade them for a few hours during bright sunshine, or the foliage will be unduly browned by sudden exposure. Protect the front row of pots, the same as advised for Ericas. Syringe the plants freely, and do not allow them to become dry at their roots.

Camellias.—When these have completed their growth syringing should be stopped for a time until the flower buds are set. Plants in vigorous growth if kept close and moist are liable to start again into growth; this can be prevented by the admission of more air, a drier atmosphere, and the gradual exposure of the plants to light. The latter is most important where strong growth has been made, for if not thoroughly matured the flower buds may fall prematurely. Plants that are swelling their buds should be kept moist at the roots and syringed freely. If confined in pots or narrow borders stimulants may be given. If these plants are placed outside they must have a position where they will receive partial shade, and must be well watered, also syringed during bright warm weather.

Kalosanthes.—Plants that have flowered may be cut back and placed in frames to break, when they should be repotted. Shoots that have not flowered may be rooted singly in small pots, or a number placed together in 5 and 6-inch pots. These plants, if rooted quickly, and then fully exposed to light and air, will flower freely another year. If wanted only for the season following, root them singly, and then remove the point to induce them to branch. Plants cut back last season should be placed outside fully exposed to the sun to ripen, which will induce every shoot to flower freely.

Euonymus latifolius variegatus.—This is equally as ornamental in the greenhouse or conservatory during the autumn and winter as the Croton is in the stove, and plants of various sizes may be used with effect. Low standards on stems from 1 foot to 18 inches high are very useful. Cuttings of young wood should now be inserted thickly together in pans of sandy soil, well watered, and then placed in a cold frame where they can be shaded from the sun. Nearly every one will root in this position, and may be potted singly early in the year. They can be rooted in heat, but are less certain, and entail more than double the labour. By rooting a few annually there need be no deficiency of stock.

THE BEE-KEEPER.

Driving Bees.

Although driving bees is now pretty well understood by the majority of bee-keepers, still one cannot shut one's eyes to the fact that there are many bees destroyed annually throughout the country. Within the past fortnight I have met several bee-keepers who still cling to the tradition of their forefathers, and suffocate their bees over the sulphur pit. In discussing the subject with them, I found their ideas were as dissimilar as was possible. One bee-keeper who started with two stocks in straw skeps last spring, which have now increased to half a dozen, intended reducing them to the same number again, and when appealed to, the only excuse given was that "there was no danger of being stung, and it entailed but little trouble." The reason given by another bee-keeper was that he had sufficient bees, and if he saved their lives now they would probably die of starvation during the winter. But to the credit of modern bee keepers it is only the straw skeppists who destroy their bees when taking their honey in the autumn. Strong colonies invariably winter well; for this reason, if an increase of stocks is not required, it is an advantage to add the driven bees to existing stocks.

In driving bees from straw skeps either open or close driving may be practised. I prefer the former, as the movements of the bees can be seen at a glance; and when the queen and the bulk of the bees have been seen to go up into the empty skep it may at once be removed, and the remaining bees brushed off the combs as they are removed one by one from the stock hive. In open driving it is necessary to have two pieces of stout wire about 1 foot in length. The points should be turned about an inch at right angles. These will form a hinge on each side of the skep to be operated on. The skep containing the honey and bees must be reversed from its original position, and the empty skep placed on the top, a straight piece of wire being put through the two edges to prevent the empty skep slipping off. This will allow an open space of at least a foot between the front edges of the two hives.

The operator must then continue tapping the bottom hive, and in less than half a minute the bees will commence to run up rapidly into the empty straw skep. Before removing the stock from its original stand it is advisable to blow in a little smoke, at the same time giving the hive a few sharp taps with the hand, as this will cause the bees to become excited, and they will at once commence to fill their honey sacs from their unsealed stores; and as in the case of natural swarming, when the same thing takes place, it will make them good tempered, and they may be handled with impunity. If a fine day is chosen for the operation, preferably when the sun is shining, all the bees may be got out of a strong colony in a few minutes.

Bumping Bees.

If a colony of bees is weak from any cause, it is much easier to practise the bumping system than to drive them. This is done by first preparing them as for driving. On lifting the skep from its stand first remove the cross sticks. This is easily done from the outside, as the ends should always project at least an inch for that purpose. The skep must then be lifted bodily and bumped on the ground sharply, first on one side, and then on the other; this will break the combs from the crown of the hive. They may then be lifted out, and the bees brushed off with a fowl's wing. It is an advantage to remove the hive to be operated on a few yards from its original stand; if to a sheltered spot fifty or more yards away so much the better, as at this season robber bees from other hives are very troublesome. If honey is uncovered near to a strong colony they will quickly find it out, and if the weather is warm, as at present, will remove it in an incredibly short space of time, causing an uproar throughout the apiary, and when they have once taken to the robbing propensity it is often difficult to stop them.

Uniting Bees.

At this season, when numerous stocks are being driven in various parts of the country, no mistake must be made in uniting the bees. When all are obtained in the same apiary, or neighbourhood, it is advisable to unite them the same evening, or at the time they are driven, or otherwise obtained. Two, three, or four stocks of bees may be placed together, according to the number of bees in each. They should be headed by a young fertile queen, hatched during the present year. Before commencing operations it is advisable to mark each skep, whether old stock, first swarm, or cast; the former, if it has swarmed, and the latter, will have young queens, whereas the first swarm will be headed by an old queen,

which should be destroyed. If the operator is an adept he will readily find the queen.

If they are placed on a frame hive on fully drawn out combs, and fed rapidly with about 28 lbs. of sugar, they will come out strong and healthy in the spring. If driven bees are placed in a hive and it is necessary to afterwards add more bees, they should all be sprinkled with thin syrup or flour—the latter I prefer, as it is clean, and does not cause robbing from other colonies. The bees will then unite readily without the loss of a single bee. If driven bees are added to a strong colony the same process must be carried out, or it will result in failure.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," *8, Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Paper Receptacles for Plants (*R. B.*).—Your "idea" of forming stout paper receptacles "for the carriage of plants instead of the ordinary clay pots" has been the idea of someone else for a very long time, and, therefore, whatever the advantages of your "invention" they have been in operation for some years. We have seen hundreds of similar receptacles, and though not exactly the same as yours they serve precisely the same purpose. We do not know whether they are patented or not, but if they are we fear yours would be an infringement. If the originals are not patented your chance of making yours pay would depend on their price and your business enterprise. As you reside near Liverpool why not consult Mr. Ker of Aigburth, or send samples to Messrs. Clibran & Son of Altrincham and hear what they have to say on the subject? They are gentlemen of great experience in the packing of plants, and may be able to tell you more about the receptacles already in use than we can.

Eucharis not Flowering (*B. T.*).—To keep Eucharis five years without flowering is very disheartening, and may be due to some peculiarity in the variety or to defect of management. Plants badly infested with mealy bug, and the damage inflicted in cleansing cannot be expected to do much for some time afterwards, and the storing of them under the stage, so as to completely dry off the foliage, would not tend to mend matters, but the reverse. As the plants have not been potted for five years there would be no harm in potting them, if properly done and the plants well attended to afterwards, though needless root disturbance is not advised. First then, to get the plants to flower, we should place the pots in a light position in the stove as near as may be to the glass, and water them so as to induce growth without delay, keeping moist but not over-watered until they have made good foliage, when supply liquid manure not too strong. This, with foliage, will give fine bulbs, and without them it is useless to expect flowers. Keep the plants rather dry after the foliage ceases to develop or young leaves to be pushed, but not to the extent of causing the foliage to become very limp and die. After about six weeks of this treatment flower scapes may show, then supply liquid manure and continue until the new leaves following the flowering are fully developed, when keep rather drier as before, and you may possibly get the plants to flower two or three times in a year instead of not once in five years. The temperature during the growing period should range from 65° to 75° or 80° in summer, with 10° to 15° rise from sun heat; 55° to 65° at resting is suitable. We simply keep the plants in the stove, rather drier when the leaves are matured, and have two lots of flowers, sometimes three, in a year. Avoid complete drying, which is not essential to the free production of flowers, but very weakening to the bulbs. If potted in good soil in the first instance it will not be necessary to do more than top-dress the plants annually, repotting only when the bulbs are overcrowded.

Cutting Muscat of Alexandria and Foster's Seedling Grapes a Week Before Exhibiting (*T. C.*).—It does not answer, as a rule, to cut Grapes a week before exhibiting them, as when not perfectly matured the berries are liable to shrivel, and certainly colour no better off the Vines than on them, even when kept in water—that is, the end of the cut growths. They require light, and this you may secure by drawing the leaves overshading the fruit aside, so as to admit more of it to the Grapes. This, however, must be done very cautiously, or the fierce rays of the sun falling on berries directly that have been more or less shaded may result in scorching, and if not that, browning, which is far worse than imperfectly ripened Grapes, as clearness goes a long way in securing prizes.

Turfy Loam for Growing Good Cucumbers and Grapes (*T. W.*).—The soil appears of a sound bodied nature, such as may be expected on the outcrop of the greensand, and there meeting with clay of a substantial character. But there is little grit in the sample, the soil being of a vegetable nature, no doubt due to the accumulation of decayed organic remains, hence would require an addition of not less than 2½ per cent. of best chalk lime to make it suitable for either Cucumbers or Vines; or you may use in mixture with it one-sixth of old mortar rubbish, which would give you the lime slowly available over an extensive period, and quite enough in each year for the requirements of the Vines, "artificials" containing phosphate and sulphate of lime, such as superphosphate, being annually used. Basic slag phosphate and kainit could also be used in such soil with great advantage, using 14 lbs. of the first and 7 lbs. of the latter to each cubic yard of the turf. You would, of course, use other materials for keeping the soil sufficiently open for Vines, we not having found anything better than calcareous or marly gravel, and of this we advise about one-sixth for mixing with the turf for Vines. The red gravel overlying chalk also forms excellent material for mixing with soil such as yours, the Grapes then colouring like Sloes.

Erica Shannoniana (*R. J. D.*).—This is a superb large-flowering species, bold in growth and much branched. The leaves are arranged in

FIG. 23.—ERICA SHANNONIANA.

threes. The flowers are produced in large terminal whorls, are flask-shaped, delicate pink or flesh colour, save at the contraction of the neck, where the colour is more intense. The footstalks and calyx are bright red, and the whole flowers glutinous.

Tomato Diseased (*W. M. H.*)—The Tomato is virulently suffering from Tomato rot fungus (Macrosporium tomati), commonly known as "black patch," "black spot," or "black stripe," and the whole life history of the parasite was clearly definable in the specimen, so far as necessary for practical purposes. In the early stages the fruit has the appearance of having been scalded, as the attack causes the flesh to leave the skin, which appears quite white, and the patch or stripe quarter to half inch across at first. This enlarges as the mycelial hyphæ of the fungus eat the flesh away, when the affected part assumes a

blackish olive colour, and the whole fruit, or greater part of it, in bad cases becomes involved, turns black inside and rots. The disease is due solely to the fungus, but can be avoided by cultural methods. The most important points to attend to are:—1, Practise thorough cleanliness in the house, removing from it every particle of old plants and vegetable matter, cleaning the woodwork with petroleum emulsion solution, and washing the walls or boarded sides of the house with hot limewash, each pailful having a handful of flowers of sulphur in it. 2, Supply quicklime to the bed or border, 1¼ cwt. per rod; and, after slacking, dig in with a fork a foot deep, taking small spits, so as to insure an even distribution of the lime. 3, After lying a time use thoroughly decayed manure, if any, for enriching the soil, and incorporate well with it. This will also tend to a better intermingling of the lime. 4, Employ such soil as that perfectly free from partially decayed or rough vegetable matter for sowing the seed. 5, Give the seedlings plenty of light and air from their appearing above ground, it not being possible to have them too sturdy. 6, Have the soil firm for the plants, whether planted out or grown in pots. 7, Afford air day and night after the trusses of bloom appear, so that the foliage and flowers and fruit may dry quickly if syringed, and moisture not be deposited. 8, Fertilise the flowers carefully, either by rapping with the finger jerked on the shank, or with a camel's-hair brush. 9, Remove the corollas directly the fruit is set, and they part freely from the surface, not leaving them to damp and rot. 10, Rub the part thus cleared gently with a moisture of air-slaked best chalk lime and flowers of sulphur in equal parts well mixed, or preferably, apply with a fine soft brush. 11, Paint the hot-water pipes with a cream formed of flowers of sulphur and skim milk, and occasionally heat them to 170°, so as to give off fumes, never being afraid to have a little warmth in them in dull weather or when needful to keep the air in motion. 12, Avoid the use of straw or partially decayed manure as a mulch. 13, Feed by means of "artificials" washed in or liquid manure. These points attended to, the disease may be greatly mitigated if not prevented. It is damp on the fruit, held by the decaying calyx, that aids the fungus germ tube to enter from the germinating spores. These come from dead stems or parts of plants that have been affected by the fungus and in which the parasite mostly lives over the winter, again giving rise to the malady. No less than four germ-tubes have entered the fruit sent at its eye, and their mycelial hyphæ are rampant in the flesh, destroying the tissues and causing the fruit to become black inside. Do not save seed from affected fruit. As a further precaution, you may dust the plants with a fungicide in powder containing 10 per cent. of sulphate of copper, keeping the trusses coated very lightly, applying with a bellows apparatus. The other procedure, however, has proved very satisfactory.

Names of Plants.—(*G. C.*).—Cimicifuga spicata. (*F. M. L.*).—1, Harpalium rigidum; 2, Chrysanthemum maximum; 3, Pyrethrum uliginosum; 4, Erigeron speciosus. (*Lex*).—1, Adiantum grandiceps; 2, Nephrolepis davallioides furcans; 3, specimen insufficient, possibly Kentia canterburyana; 4, Cocos Weddelliana; 5, Maranta major; 6, Pteris cretica. (*Hants*).—Rubus odoratus. (*J. C. J.*).—1, Monarda didyma; 2, Catananche cœrulea; 3, Pentstemon Wm. Rollinson; 4, Cornus sanguineus; 5, Œnothera macrocarpa; 6, an Argemone. (*M. H. S.*).—Staphylea colchica. (*Orchid*).—Cattleya Loddigesi.

POULTRY SCHOOLS FOR ENGLAND.

IN these days of advanced science, when everyone has a chance of learning how and when he likes, and going either deeply or superficially into matters great and small, it is almost a wonder that more has not been done to encourage and foster aviculture, or, in other words the science of breeding and rearing fowls.

Early in this decade steps were taken by County Councils for the development of technical education in the small villages as well as in the large and busy centres. Pupils have been taught by means of lectures, demonstrations by teachers, and also by practical work done by the pupils. The subjects have been very diverse, but not more so than the pupils. You will see the grey-headed man and the boy just out of school eagerly listening and learning together; you will see the mistress of a large household, her young daughter, and possibly one, if not more, of her servants attending the same class.

In the country districts dairy work, laundry work, and cooking classes have filled the best, and, we should add, health lectures and nursing lessons have come in for their full meed of favour. We have had veterinary classes for the men, and a few poultry lectures for all. The gentlemen delivering the latter have made a practice, as far as time would allow, of visiting poultry yards and giving the owners advice—very capital advice too.

But poultry keeping, to make the very best of it, is not to be learned by attending a few lectures. No man, however clever, can compress all he wants to tell in three or four hours at most. That there is great need for reform in this minor industry no one for a moment doubts. We all thought we knew how to make butter—we certainly all did make some substance, sometimes good, sometimes middling, sometimes only fit for cart grease. Now we find that by sending our daughters and dairymaids to undergo a short course of systematic training our butter making has become a science and art—no longer an unknown or doubtful quantity. So far so good; but till we can manage to lessen the amount of money that goes out of this country annually for eggs and poultry we must, in all fairness, admit we have much to learn in poultry management. Our bill last year came to £4,608,606, and we do think some at least of that might be kept at home to help line our empty pockets.

A step in the right direction has been taken lately, and we hail it with pleasure, believing it only to be the forerunner of a great movement. Some of our County Councils have, and are, arranging for classes for fifteen days or three weeks, practical classes where the work is entirely done by the pupils. Of course cavillers will say three weeks is not enough; but we think an intelligent pupil may in that time grasp sufficient facts that will enable him to continue his own education. The classes have been held during

afternoons and early evenings, and at the close of the evening class a lecture is delivered to the general public.

In the district with which we are acquainted our technical pundits have been fortunate in securing the services of Mr. Ed. Brown, the well-known poultry expert, and we have just read with greatest interest his account of how these things are managed in France. France produces yearly eggs and poultry to the handsome amount of £14,000,000, and although much of this is due to individual enterprise, yet the government is wisely alive to the necessity of fostering and helping this industry.

In the Department of Seine et Oise is the village of Gambais; four miles from the town of Houdan (does not that name recall the black and white crested fowl?) is the poultry school. The objects of the school are—1st, to give young people coming from the State practical schools, and who are destined to conduct a farm or any agricultural work, a complete course of practical studies dealing with the poultry yard and production of fowls; 2nd, to render students capable of conducting a poultry establishment, including the hatching, breeding, and fattening of fowls by practical methods, artificial and natural.

The usual course is for three months, and the terms are £14, inclusive of board and lodging. There are scholarships in connection with this school, which of course minimise the cost of the course.

The authorities allow other than French pupils, and at present Mr. Brown says there are three English pupils there. The time-table, which we copy, shows not much idleness is allowed.

6 A.M.—Opening of yards, distribution of food throughout the establishment, first cramming of fatting fowls.
8 A.M.—Hatching room, followed by breakfast.
9 A.M.—Care of chickens, general cleaning of breeding houses, fowl houses, &c.
11 A.M.—Dinner.
1 P.M.—Second cramming of fowls.
2 P.M.—Distribution of food, refilling water troughs.
3 to 6 P.M.—Theoretical studies.
6 P.M.—Supper.
7 P.M.—Closing of poultry and breeding houses.
8 P.M.—Third cramming of fatting fowls.

The day is pretty well accounted for, and at this rate in three months the pupil must be good for nothing if he has not grasped the situation. Fancy, hatching out 30,000 chickens in a season. Nature has but little hand in this process, the greater number being hatched in incubators, and reared in brooders, which are artificially warmed. A great many of these chickens are sold at a day or two old, and reared elsewhere.

Now this seems to us a most excellent plan. We should all like early chickens, but hens are not so accommodating in the matter of sitting as we could wish. Incubators are perhaps not exactly dear, but they involve certain expenditure, and the results for amateurs are not always satisfactory.

As to the fatting process, three methods are taught—the hand, the funnel, and the machine. The food used seems most nutritious, consisting as it does of finely ground and sifted barley-meal, with occasional additions of maizemeal and skim milk; just at the last 1 oz. of diluted fat is divided between three birds, or an egg beaten up to every pint of liquor.

Together with the runs, which, by the way, are planted with fruit trees, is a certain amount of woodland. In hot weather these trees afford grateful shade, and also provide a little insect food. We cannot but agree with Mr. Brown that a school of this description would be a boon to many English folk, and Government might easily spend money far less wisely than in founding and supporting such an institution.

We want something both cheap and good, for the majority of the pupils would not be overflush of money, and we think a few scholarships connected with our elementary schools would be of more practical use than those existing—scholarships that provide what is called "higher education."

WORK ON THE HOME FARM.

The past week has been exceedingly hot and dry, and we have now had nothing more than a passing shower since July came in. We hear of heavy rains in more favoured localities, but alas! they do not come our way. Roots look bluer every day, and it is wonderful how the Turnips exist. Mangolds look fairly well, but want rain so as to make the best use of the last dressing of nitrogen.

The harvest that was inclined to tarry has come with a rush, and before these lines are in print we shall be in the thick of it. Oats have finished off very suddenly, and must be light in weight; and Barley, except on the deepest soils, will be thin in the grain, which must seriously affect the yield. The heat has been too great even for such a sun-loving plant as Wheat, and many samples will be wanting in plumpness.

This promises to be a great season for the string-binder. Looking round our own parish there does not appear to be one field that is beyond the binder's powers, and as reports from all parts tell a similar tale, hand-binding is likely to be the exception rather than the rule. Reapers should work excellently this season, and the draught will be light, but the hard ground will shake them a good deal, and nuts and screws must be constantly looked over and tightened up, or they may be lost.

Seeds are now as bare as a turnpike road, and might have been ploughed for Wheat for all the keeping there was left on them, but the land is as hard as the aforesaid turnpike, and would be about as easy to plough. An immense amount of rain will be necessary to bring it into ploughing condition.

The chief anxiety of the farmer just now is in connection with his live stock. The best of pastures are presenting a brown appearance, and growth is quite at a standstill. Already we see cuttings being made in the recently made hay and clover stacks. Water supply is in some cases a serious question; streams and ponds are drying up, and the dryness of the pasture makes doubly necessary a good supply of water. This will mean carting, may be long distances; but harvest time or not, the water must be fetched. What a pity it is that fine weather can do so much harm; but complaining is of no use, we must make the best of things as they are.

TO HELP FARMERS.

Her Majesty's Commissioners appointed to inquire into the subject of agricultural depression have issued a report, in which they recommend some important amendments of the present Agricultural Holdings Acts for England and Scotland.

Among the proposed amendments are:—

1, Full compensation for the cumulative fertility resulting from continuous good farming, irrespective of any arbitrary time limit.

2, Freedom to carry out and compensation for all improvements suitable for the purposes for which the holding is let, whether the landlord consent or not.

3, Compensation should be given retrospectively for suitable improvements prior to the passing of a new Act, where the landlord did not dissent from such improvements at the time.

4, A tenant remaining in his holding at the determination of his tenancy and entering on a new contract of tenancy should be enabled to protect himself from being rented on his improvements by the right to claim compensation for their unexhausted value without quitting, or to obtain a proportionate reduction from the new rent.

5, A tenant arbitrarily compelled to quit his holding, except for non-payment of rent and for bad farming, should be entitled to such compensation as will cover his loss.

It is also suggested that the Railway and Canal Traffic Acts should be amended, so as to test the reasonableness of every rate or condition of transit.

The First Pocket of Hops.—The first pocket of Hops of this season's growth arrived on Monday, consigned to Messrs. W. H. & H. Le May, Hop factors, Borough High Street, and was sold by them at £15 per cwt. It was grown by Mr. T. Savage of Beech Farm, Marden, and was of the kind known as Hobb's Early Goldings, the quality being exceptionally fine. It is thirteen days later than the first pocket arrived last year.

REMARKS.

1st.—Overcast morning; bright pleasant afternoon.
2nd.—Almost cloudless throughout; warm sun and pleasant breeze.
3rd.—Slight mist or drizzle early and overcast till 10.30 A.M.; bright warm afternoon.
4th.—Sunny and warm throughout.
5th.—Hot and rather close; cloudy at times in morning.
6th.—Cooler, with alternate cloud and sunshine and occasional spots of rain.
7th.—Alternate sun and cloud.

A very fine, hot week—four consecutive daily maxima above 80°, and only one day with maximum in sun below 120°.—G. J. Symons.

Journal of Horticulture.
THURSDAY, AUGUST 19, 1897.

THE JOURNAL OF HORTICULTURE *can be obtained from the Office,* 171, *Fleet Street, London, post free for a Quarter,* 3*s.* 9*d. Editorial communications must be addressed to* 8, *Rose Hill Road, Wandsworth*

SHREWSBURY.

QUITE a sufficient heading is that one word to direct the minds of readers of current garden literature to an event which cannot be otherwise than historic. During the latter part of 1896 a strong desire was manifested by horticulturists that something should be done by them as a body to commemorate in a fitting manner the greatest consummation of its kind that is to be found in the annals of any country—the occupancy of the Throne for sixty years by our good and gracious Queen.

Varied were the projects advanced in which the sentiments of horticulturists might be embodied and exemplified, but however excellent in themselves, the majority of them were thought, after serious consideration, to be lacking in the element of practicability. True, and happily, those connected with our charitable institutions did not come within that category, but were splendidly successful. There was, however, beyond them a desire for something of a spectacular character, as represented by a great display of the products of British gardens.

An exhibition, adequate in magnitude and diversity, could not be provided with anything approaching a guarantee of success in London after the 22nd of June, and it was fortunately not attempted. The Royal Horticultural Society had had its splendid, and in many respects unequalled, Show in the Temple Gardens. That great annual exhibition could not be postponed, and, as we said at the time, whatever the R.H.S. might do in providing a second exhibition, it could not, in our opinion, be made to assume a national character, or be in any adequate sense representative of British horticulture in its broadest aspects.

The Council of the Society marked the great event of the year in a different and much more permanent manner by instituting, with the full sanction of her Majesty, the "Victoria Medal of Honour," of which it may be presumed there will always be sixty possessors so long as the Society exists. In the first distribution the most distinguished scientific men, as well as generous

patrons of, and real workers in, horticulture, become its recipients, except those gentlemen who happened to be members of Council at the time—these, in virtue of a self-denying ordinance, being regarded as ineligible. It could not well be otherwise under the circumstances, but there ought to be ways and means by which recipients themselves who are Fellows of the Society may claim at an appropriate time, that at least the President and Secretary of the Society shall be *ex-officio* entitled to this distinction, seeing that they are in fact more than fully entitled by the commanding services they have rendered in the world of horticulture. This may be somewhat digressive, though it is strictly cognate to the subject under discussion—the commemoration of the great reign by the gardening community.

Adverting to other forms proposed for accomplishing the object in view in the most effective manner, and in which there could scarcely be the possibility of failure, the *Journal of Horticulture* ventured to distribute at the time the following pronouncement :—

The Shrewsbury shows never fail ; they are the greatest representative exhibitions in Europe. Nowhere else can such a splendid combination of specimen plants, groups, floral decorations, fruit, and vegetables be seen exhibited by such a great number of cultivators—nurserymen, amateurs, gardeners, and cottagers ; and nowhere else, so far as we know, do such crowds of people assemble to inspect the productions. The shows are of the first magnitude every year, and if the Royal Horticultural Society and Shrewsbury were, so to say, join hand in hand in honour of an event which will stand alone in history, the exhibition resulting would be of a regal character and worthy of the great occasion.

A cordial invitation was received by the Royal Horticultural Society from Shrewsbury, and as cordially accepted. The great National and strongest of provincial Societies joined hands. We have said the "strongest" of provincial Societies. By what test is it so adjudged ? By the test of success. Since 1875 the progress has been remarkable, as determined by the financial results.

With exceptions so small as to scarcely be worth notice, the subscriptions of members have increased year by year. Visitors have increased in numbers, and the income of the Society has risen correspondingly. The total amount received from all sources in 1875 was £791 12s. ; in 1895 (we have not the returns for last year) it was £4010 13s. 2d. Assuming that the last year's amount equalled that of the year preceding, the aggregate receipts in twenty-two years have exceeded £50,000. That is an indication of strength. Even in 1894, when the rain fell in torrents through the whole of one day, we find the total amount realised £3476, which most societies would rejoice in under the favourable influence of the best flower show weather.

Remarkable also have been the disbursements of the Shropshire Society—not in the form of prizes alone, of which we have no record, but as grants for various public objects connected with the town. These have exceeded £10,000, the largest amounts being £5700 in the purchase of land and river foreshore, and £1000 for the Darwin Memorial Statue, which was unveiled on the 10th inst. by the Right Hon. Lord Kenyon. These facts, we think, afford sufficient testimony of the strength and stability of the Shropshire Horticultural Society, of which his lordship is president, and thus appropriately presented the statue to the town. We know of no Horticultural Society at home or abroad which has accomplished so much in the time—twenty-two years.

We may now briefly refer to the preparations that were made for the present commemorative show, and inducements offered to competitors. Not only did the Royal Horticultural tender hearty co-operation generally, but at once offered its gold Banksian medal for the exhibit (not for competition) which in the opinion of the Council best represents the progress of horticulture during the last sixty years, as well as a silver-gilt Knightian in one of the great fruit classes, with such other medals and awards as the Council may decide.

An ancient London Guild — the Worshipful Company of Fruiterers—make a handsome donation in the form of a gold medal to go with the first prize of £30 in the Victorian fruit class. This may be regarded as the blue ribbon of the Show. The Company also provides three silver medals, one for a collection of fruit, the other two in the Grape classes. Then there is the Veitch Memorial medal, two Victorian medals by the President, specially designed, and of which no duplicates will be issued. Of the same unique character are the three first dessert services, provided by the Shropshire Society, which is also prepared to grant gold and silver medals for new plants, also for products of special merit.

It will be seen that generous provision is made for exhibitors, apart from money prizes, some of which are of exceptional value. For instance, upwards of £130 are allocated to groups in two classes, and £45 for specimen plants in two prizes ; while £48 are devoted to seven collections of cut flowers, and £37 in a class for floral arrangements. Generous provision is made for vegetables by Messrs. Sutton, Carter, Webb, Sydenham, Eckford, and others, as may be seen by the schedule.

It will thus be perceived that encouragement is not lacking in any sections, and as the entries are greater than ever in the principal open classes, it may be expected (writing on the eve of the show) that a realisation worthy of the occasion will soon be reported to the world.

SHREWSBURY, TUESDAY.—An idea of the magnitude of the show may be gathered from the extent of the accommodation provided for the products. The extensive park-like quarry grounds, bisected and partly encircled by noble avenues, seem to be, in the show section, almost full of canvas. Other sections are clear, as must be the case when some 50,000 persons assemble at once. We think the total attendance amounted to 70,000 last year. There are seven marquees of the following dimensions :—Large plant tent, 180 × 80 feet ; second plant tent, 135 × 40 feet ; flower and fruit tent, 310 × 50 feet ; second flower tent, 100 × 36 feet ; vegetables, 120 × 30 feet ; cottagers, 130 × 36 feet ; small tent, 35 × 20 feet—a total of 47,880 square feet of canvas.

The number of judges (26) further indicates the extent of the exhibition, and in the following list there is not one too many for the work.

GROUPS AND SPECIMEN PLANTS.—Mr. A. Outram, F.R.H.S., Moore Park Road, Fulham, London, and Mr. H. Ranger, R. Kerr & Sons, Aigburth Nurseries, Liverpool.

FLORAL DESIGNS, BOUQUETS, AND CUT FLOWERS.—Mr. J. Hudson, V.M.H., F.R.H.S, Gardener to Messrs. Rothschild, Gunnersbury ; Mr. P. Blair, F.R.H.S., Gardener to the Duke of Sutherland, Trentham ; Mr. A. McKellar, Gardener to H.R.H. The Prince of Wales, Sandringham ; and Mr. S. T. Wright, Superintendent R.H.S. Chiswick.

DESSERT TABLES.—Mr. Owen Thomas, V.M.H., F.R.H.S., Gardener to H.M. The Queen, and Mr. A. F. Barron, V.M.H., F.R.H.S., late Superintendent R.H.S., Chiswick.

VICTORIAN 60 DISHES FRUIT CLASS.—Mr. J. Wright, V.M.H., F.R.H.S., *Journal of Horticulture*, London ; Mr. C. Slade, Gardener to the Duke of Newcastle, Clumber ; and Mr. W. Coleman, Eastnor Castle, Ledbury.

GENERAL FRUIT CLASSES.—Mr. E. Gilman, F.R.H.S., Gardener to the Earl of Shrewsbury, Alton Towers, and Mr. W. Miller, F.R.H.S. Gardener to the Earl of Craven, Combe Abbey.

COLLECTIONS OF VEGETABLES.—Mr. J. Muir, Gardener to Miss Talbot, Margam Park, Glamorgan, and Mr. J. Lambert, Gardener to the Earl of Powis, Powis Castle, Welshpool.

SPECIAL VEGETABLE CLASSES.—Mr. A. Dean, F.R.H.S., 62, Richmond Road, Kingston, and Mr. H. W. Ward, F.R.H.S., Rayleigh Nurseries, Rayleigh.

GENERAL VEGETABLE CLASSES.—Mr. N. Pownall, Gardener to F. Wright, Esq , Lenton Hall, Nottingham, and Mr. J. Wallis, Gardener to R. Sneyd, Esq., Keele Hall.

WILD FLOWERS.—Messrs. W. Beacall, Shrewsbury ; T. P. Blunt, Shrewsbury ; and Rev. W. Serjeantson, Acton Burnell.

COTTAGERS' CLASSES.—Mr. Farrant, Gardener to Mrs. Juson, Shrewsbury ; Mr. Bellis, Gardener to Sir C. H. Rouse Boughton, Bart., Downton Hall ; Mr. Townsend, Gardener to Col. Lloyd, Aston Hall, Oswestry ; Mr. Bremmell, Gardener to H. France-Hayhurst, Esq., Overley, Wellington.

Something like a calamity has now to be recorded. The wind was gusty before noon, and just when Mr. Cypher had arranged five van loads of plants in the large tent, it collapsed, doing irreparable damage to his specimens. There was no such storm as at York

but the ropes were not strong enough to resist the sudden strain to which they were subjected, and surprise and regrets are heard on every hand. Some of Mr. Marriott's plants were also injured.

The town is gay, hotels filling fast, exhibitors jostling each other at the station, and porters having a lively time. A famous hotel, "The Raven," is the rendezvous of the R.H.S. contingent, except the President ("Sir Trevor") who with the Very Rev. (and horticultural) Dean Hole, are the guests of Lord Kenyon. The officials of the Shropshire Society, including Lieut.-Col Peele, Mayor of Shrewsbury, with Messrs. G. M. Salt (Chairman), W. Phillips (Treasurer), and Adnitt and Naunton (Hon. Secretaries), met the London visitors, who consisted of Messrs. H. J. Veitch, T. Statter, S. Courtauld, P. Crowley, J. Douglas, H. Selfe Leonard, W. Crump, J. Smith, T. F. Rivers, A. Outram, J. Wright, and the Rev. W. Wilks, at dinner in the evening. It was not a ceremonial but friendly gathering, speeches being reserved for the luncheon on the morrow, which is to be attended by Lord Kenyon and his guests.

This great commemorative Show was, but for the mishap to the tent, an unqualified success from a horticultural point of view. The exhibits were never more numerous, and the quality was superb. In every section —plants, groups, cut flowers, fruits, vegetables—a standard was reached that is rarely seen in or out of the metropolis. Amidst such general excellence it may appear somewhat invidious to give one the pre-eminence over the remainder, but none the less we think we may safely say that the fruit section was the best of all. Magnificent indeed were the vegetables, while the display of cut flowers was of exceptional beauty. We cannot give a detailed report—time will not permit of it—but our representative has wired the foregoing facts with the prize-winners in the subjoined classes. The enormous crowd prevented the awards being secured in several of the other important classes, while the unfortunate mishap of yesterday to the large tent made the arranging of the groups very late. The weather was rather showery. We trust it will be fine to-morrow, when thousands of visitors will flock to the Quarry. Next week a complete account will be found in our columns.

One of the most attractive classes in this magnificent Show was that for a display of floral arrangements in a space of 12 feet by 5 feet. Any design in flowers was admissible, entirely at the discretion of the exhibitor. The exhibits were very lovely indeed, and showed what can be done with flowers and foliage in skilful hands. Messrs. Perkins & Son, Coventry, who are past masters in the art of floral decorations, deservedly secured premier honours, and were followed by Miss Stevens.

The fruit division of the Shrewsbury Show is always a very fine one, and this year's was in no respect behind its predecessors. For a dessert table, decorated with plants (in pots not exceeding 5 inches), cut flowers, and foliage—table 10 feet by 4 feet 6 inches. Not more than sixteen dishes of fruit selected from a given list. Each table to be covered with a white cloth, and twelve dessert plates will be provided for each table, which must not be used by the exhibitor. Silver, electro-plate, wine glasses, and decanters excluded. Epergnes and vases for cut flowers, and plates, dessert dishes, or other receptacles for fruits must be provided by the exhibitors. Four prizes were offered, the first being Veitch Memorial medal and £5, added to £12 12s. given by the Society; the second, £12 12s.; the third, £8 8s.; and the fourth, £5 5s. The stand arranged by Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Hall, Derby, with 105½ points, received the first prize. It was a superb exhibit in every respect. Mr. J. McIndoe, gardener to Sir J. W. Pease, Hutton Hall, Guisborough, with 104½ points, was second; Mr. Harris, gardener to Lady Henry Somerset, Eastnor Castle, Ledbury, with 99½ points, third; and Mr. Gleeson, with 96½ points, fourth.

The enormous sum of £75 was offered in what was designated the "Victorian Fruit Class," which was instituted to illustrate the produce of British gardens. According to the schedule, it was for "Sixty dishes of fruit, arranged on a side table, in a space 16 feet by 4 feet 6 inches, artistically displayed with cut flowers, foliage, and not more than twelve plants in pots not exceeding 5 inches in diameter." The fruits had to be selected from a list printed in the schedule, and the judging was done by points on the scale formulated by the Royal Horticultural Society in its Code of Judging. The first prize was £30, to which the Worshipful Company of Fruiterers added its gold medal. The second prize was £25, with the silver-gilt Knightian medal of the Royal Horticultural Society, and the third £20 and the silver medal of the Shropshire Horticultural Society. The most intense interest was centred in this class, as it was the first of the kind that had been seen. Obviously the number of exhibitors could not be large, there being three only, but each staged in a really remarkable manner. The prize winners were Messrs. J. McIndoe, with 321 points, first; J. Dawes, with 297 points, second; and J. H. Goodacre, with 294 points, third. It was a most imposing class.

In addition to the several medals of the Fruiterers' Company and of the Shropshire Horticultural Society, the Royal Horticultural Society specially offered a gold Banksian medal for the exhibit (not for competition) which in the opinion of the Council of the R.H.S. best represented the progress of horticulture for the last sixty years. To the superb exhibit of Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea, this was adjudged.

Messrs. Sutton & Son, Reading, offered six prizes for a collection of vegetables, nine distinct kinds. Mr. C. Foster, gardener to Morgan S. Williams, Esq., Aberpergwm, Glyn Neath, Glamorgan, was first, and took the Sutton Commemorative cup, with £5. The stand was an exceptionally fine one, and reflected the utmost credit on the grower. The second position was taken by Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury; the third by Mr. Bowerman, gardener to T. Hoare, Esq., Hackwood Park, Basingstoke; and the fourth by Mr. C. J. Waite, gardener to the Hon. W. P. Talbot, Glenhurst, Esher.

Presentation to the Honorary Secretaries.

An interesting feature to be recorded in connection with the show is a well merited presentation to Messrs. H. W. Adnitt and W. W. Naunton, who have been so largely instrumental in raising the Shropshire Horticultural Society to its present high position. Having in view the long and gratuitous services of those gentlemen, a Committee was formed a short time ago with Mr. A. Outram, F.R.H.S., as Secretary, and Mr. Owen Thomas, F.R.H.S., V.M.H., as Treasurer, and an ample sum speedily raised for the purchase from Messrs. Mappin & Webb of two handsome silver centrepieces (in appropriate design for fruit and flowers) for the dinner table, each bearing, in addition to the names of the recipients, the following inscription:—"Presented by horticultural friends in recognition of services to horticulture." Sir Trevor Lawrence kindly undertook to make the presentation.

It is impossible to speak too highly of the labours of these gentlemen. At no time, perhaps, could these be more fully appreciated than the day before the show, when, with a staff of clerks (and half a cartload of empty envelopes on the floor), they were dealing with correspondence, while telegrams were constantly pouring in. They are, however, adepts at the work, and out of the seeming confusion to-day will emerge order to-morrow, to the satisfaction of thousands and the advancement of horticulture.

Eucryphia pinnatifolia.—Possibly the reason this beautiful shrub is still so rare is that it is rather difficult to propagate, and plants until three or four years of age are liable to be damaged by severe frosts. It is, however, well worth looking after, as when fully in flower it makes a most charming effect. It forms an upright growing bush, with a somewhat fastigiate habit, and is of Chilian origin. The leaves are usually ternate and opposite, the leaflets being more or less ovate, with serrated margins. The flowers are produced in pairs from near the apex of the branches. They are pure white, 3 to 4 inches across, with four petals and numerous stamens, resembling at first sight the flowers of a single white Camellia. The flowering period is July and early August. It looks best when grown as a single specimen. Good soil with a little peat ought to be given, and a sunny position. It should be well planted at first, and then not interfered with, as it dislikes disturbance at the roots. It will be found advisable until the plant has had several winters outside to have a temporary covering which can be placed over it during severe weather, and which can be easily removed on all favourable occasions.—W. D.

Window Gardening in Manchester.—Have you ever been to a plant competition in some dingy quarter of a large city? If so, you cannot have failed to be impressed with the enthusiasm that is manifested by the poor people competing, or cease to be struck with admiration that under such adverse circumstances they have accomplished so much. How, for instance, they manage to get anything but stem and a few pallid leaves on a "Geranium," or prevail upon a Fuchsia to give ample bloom, or maintain their plants in good form, would be matters of marvel but for the knowledge of the great care that the exhibitors take to keep their plants clean and to give them every ray of light and plenty of air, with prudence in the use of water. All this care and thought, which are as much as would be required to keep a whole greenhouse in good order in the country, have their reward in the wholesome pleasure they give to those who are so circumstanced in life as to have but few reliefs to the dreary drudgery and sordid surroundings of their lives. We are pleased to see the strides the Society for Promoting Window Gardening in Ancoats is making. The recent show was larger than any yet held. It would be a good thing if so excellent a movement were extended to other districts of the city.—("Manchester Evening Chronicle.")

FRUIT GROWING AND SELLING.

The difficulties attendant on the cultivation of hardy fruit in this climate are frequently recounted in the pages of the horticultural periodicals. Every phase of the subject is described, and the available means for combating many of the evils are explained; in short, it is the fault of neither writers nor editors if cultivators are unable to cope with most of their disadvantages. There is, however, one aspect of fruit culture which demands more attention—in fact, it is so essential that the greatest cultural success is nullified by defective knowledge in the profitable realisation of the fruit produced.

This is of more importance now, because in so many private gardens the sale of surplus produce is an established rule, while in others only that which cannot be sold is sent into the "house;" but whether the marketing is done from private establishments, orchards, farms, or market gardens, all those responsible have to study the most economical and advantageous methods of finding purchasers for the fruit, vegetables, plants, or flowers they are engaged in producing.

Many who have had to buy their experience can tell how easily the balance of accounts is placed on the wrong side, and upon what simple matters profit or loss frequently depends. Certainly in this matter "an ounce of practice (*i.e.*, experience) is worth a ton of theory," as those who endeavour to found a business on theory alone speedily find to their cost. The experience which has fallen to my lot has been varied, and in some respects exceptional, and this has familiarised me with aspects of the subject which often escape notice or receive only partial attention.

A friend who is now securing a substantial living from the culture of hardy fruits called upon me a few days since, and in the course of conversation remarked, "Twelve years ago I knew practically nothing of hardy fruit growing, but it seemed such a simple matter that I embarked upon it rather extensively, and it has taken me quite half that time to learn to grow the fruit, and the other half to learn how to sell it." Fortunately this individual was not solely dependant upon his fruit plantations for a living, and he was, further, in the happy position of being the owner of the land planted. But for these two circumstances it is easy to imagine what the result of such an undertaking would have been. It is creditable to a man's energy, however, that he should have conquered such difficulties, yet with dearly bought experience like this he is as ready to communicate his knowledge to others as if it had cost him nothing. He speaks hopefully of the prospects of hardy fruit culture, but he qualifies all the encouragement given to those about to start in the work with the indispensable condition that they must acquire a substantial practical knowledge of the industry before embarking in it, or risking much capital.

Without entering upon cultural questions, a few remarks upon varieties are needed to preface the subject of fruit selling, as there are certain qualities which have a strong bearing upon market value and growers' profits. Two properties of general importance are hardiness and prolificness. Delicate varieties of any kind of fruit-bearing plant are eminently unsuited for those who wish to make fruit culture profitable, and equally so are those that habitually produce sparse crops. Softness is also a quality to be avoided, and it is equally detrimental in Apples and Pears as it is in the more delicate fruits like Strawberries; while even in Plums there are some varieties with firmer, thicker, and more protective skins than others, which enable them to stand conveyance by road or rail better than their delicate and, perhaps, finer quality relatives.

In connection with this property of softness may also be mentioned the gathering of fruit before it is dead ripe. There are few points more difficult of determination by the inexperienced than the precise time when fruit can be gathered to the best advantage for marketing with safety. It is of especial importance in reference to Strawberries, Raspberries, and Plums; but even with Gooseberries and Currants the difference of a day in the time of gathering will sometimes materially influence the sale results, either favourably or the reverse.

If fruit is advanced beyond a certain stage, and it is packed to remain in bulk for some hours, or possibly a day, it rapidly deteriorates in value, even though it was thoroughly dry at the time of gathering. There is a natural exudation from fruit in this stage which leads to the heating that is really an incipient fermentation affecting both flavour and appearance most injuriously. This seems so self-evident that dwelling upon the matter might appear to be superfluous; yet large quantities of fruits are rendered unsaleable every year by neglect in the precaution of gathering sufficiently early, and a still larger proportion is sold at considerable disadvantage for the same reason. Gooseberries are quite exceptional in affording two distinct seasons of gathering, and in a year like the present, when in many districts there was scarcely half a crop, much better prices were obtained for the green fruit than is now being had for that marketed ripe. Even with only a partial crop my returns have been far more satisfactory than in some seasons of full crops.

Appearance is a most important factor in the sale of fruit. It includes size and colour, both qualities of urgent market importance, for small fruits of their respective kinds stand a poor chance for sale, except perhaps as regards the early dessert Apples, in which both season and quality outweigh the other considerations. But if size is gained only at the expense of firmness the seller will not profit. It is an unfortunate circumstance, more clearly exemplified in Strawberries than most other fruits, that increased size is nearly always attended by loss of other qualities, either firmness or flavour. There is no question, however, that size does command the public attention, for large good-looking fruits will secure purchasers when those of inferior appearance, though possibly superior in quality, are often passed over.

As regards colour the same remarks apply, for it frequently makes 20 per cent., or even 30 per cent., difference in the price. Take for example Cox's Orange Pippin, a well-known Apple of proved quality, which in different seasons or situations varies considerably in the brightness or depth of colour. I have known well-coloured fruits realise 10s. per bushel when otherwise equally good fruits on sale at the same time would not bring more than 7s. per bushel. A very material difference when railway and salesmen's charges have to be deducted from the gross returns. It will be seen that this refers not only to varieties notable for their colour, but to the selection of the best coloured fruits of the same variety.

Flavour or quality is placed last because it only appeals to those who have an intimate knowledge of fruits, and thus affects the general market to a limited extent. In leading depôts like Covent Garden there are always some salesmen who will only deal in the best produce of all kinds, and then he who has command of really first-class varieties, and has secured the confidence of purchasers, can obtain remunerative prices even when the general rates for average fruits are low. It is a trade that ought to be developed. In other words, the public require educating up to a higher standard; but where a man desires to get a living he must supply existing demands, and these are all in favour of the qualities already named.

Selecting and grading have often been described as essential to the best and most profitable trade in fruit, but they cannot be too frequently or emphatically impressed upon the minds of growers. Although the labour is considerable when dealing with produce in large bulk, yet the expense is a wise outlay, and will bring a substantial return. In my own experience instances have occurred where there would have been less actual loss if mixed, ungraded, low quality fruit had been thrown away instead of incurring the expense of carriage and marketing; yet for half the quantity carefully selected, and discarding entirely all that were defective, a profitable return has been obtained.

This applies specially to Apples; but the same thing has been proved in regard to such soft fruits as Strawberries and Raspberries, as well as Gooseberries. In regard to the latter, as much as 9s. per bushel has been made this year of the finest selected fruits for bottling, while for the lowest grade Gooseberries not more than 5s. per bushel could be secured. The labour involved in grading Strawberries is the most serious item, for the care requisite in handling such a delicate fruit is much greater than with any other, as the object should be to avoid everything likely to lessen the value of the fruit, which the slightest defect will do. Notwithstanding this, however, I have found, taking on an average of seasons, that after deducting the expenses of sorting there is a clear increase of £10 per ton due to the grading.

The mode in which fruit is made up for sale is another matter of considerable importance, and though it has to be regulated by local customs or special market requirements to some extent, yet there are certain rules that apply generally. The first of these is that fruit should not be made up in large quantities where it can be avoided, and this is especially the case with ripe fruits and all the soft fruits. Much damage is done by employing either boxes or baskets of large size. The half sieves used in Covent Garden Market are very convenient, but baskets are with many growers being gradually superseded by boxes. The chief advantage of these is that the fruit is less liable to injury in transit, and the defect, if not properly made, is that they are too close and consequently too heating.

For Apples the most convenient boxes I have tried are those constructed to hold half a bushel, imperial measure, which can be nearly square or longer in one direction, allowance being made for the packing material and the size of the Apples, the larger sorts needing most space, and the proportions of the boxes must be regulated to some extent by the size and class of Apple they are intended to hold. If the fruits can be packed in even rows both ways and,

therefore, in layers, it is more advantageous in every respect. For choice dessert varieties and Pears smaller boxes are preferable, so that the fruit can be either packed in dozens, or 10 lbs. or 12 lbs. in weight. For retail trade small boxes are very useful, and many salesmen are finding that they can secure a readier sale for fruits in small quantities than in bulk.

For small fruits, boxes holding 6 lbs. or 12 lbs. are useful, and are readily sold. A useful size of box that is employed by several growers, including myself, for Black and Red Currants and Strawberries, has the following dimensions :—Sides, 11½ inches long by 6 inches deep, and ¼ inch thick ; ends, 10½ inches long by 6 inches deep, and ½ inch thick. The sides are nailed to the ends, the bottoms being of the same thickness as the sides, but in two widths, leaving a space of ¼ inch in the centre for ventilation. The lids are nailed to cross pieces at the ends which rest on the top of the box, thus raising the lid slightly above the box, also for ventilation ; they are hinged at the back by two pieces of stout string passed through holes in the sides and lids, and are secured in front by one piece of string in a similar way. Boxes of this size will hold 12 lbs. of Strawberries, Red Currants, Black Currants, or Gooseberries, but more of the Black Currants can be put in if necessary, though it is not recommended, and for Strawberries it is not advisable to have more than 6 lbs. in one box.

With regard to the last-named fruit, the most serviceable box I have tried is one that is being sent out by several of the railway companies at a charge of 1s. 6d. per dozen. The size is as follows (inside measurement) : 10¾ inches long, 7½ inches wide, and 3 inches deep. These weigh 1 lb. each, and hold 3 lbs. of Strawberries, Red Currants or Raspberries, and 4 lbs. of Black Currants, in which quantities these fruits sell most readily, and travel safely. I have sent consignments in such boxes over 100 miles, and the fruit has been received in excellent condition. As regards Strawberries and Raspberries, the finest fruits are best in punnets, and these, again, should be packed in shallow boxes that will hold half a dozen. The 1 lb. punnets are greatly preferred to the larger size (2 lbs.), as the latter have to be heaped up, and it renders safe packing and transit more difficult of attainment.

In the establishment of a new business in fruits, the two methods open to growers are the market and local trade. In a few cases it may be possible to rely upon either of these alone, but in the majority it is safest to utilise the two. For relatively small quantities the local trade can be depended upon, and in some districts all the best fruits can be disposed of in this way ; but for large bulks of fruit of any kind, the markets provide the only available outlet. The too general mistake of sending all to the largest market, or to one market, should be avoided, for the differences in prices prevailing on the same day in markets only fifty miles apart is sometimes astonishing. It may be more convenient to forward fruit in large quantities to one destination, but the grower who studies his own personal convenience alone in this or other matters, will rarely succeed in securing the best returns for his produce.—A Fruit Grower.

A GOOSEBERRY TRELLIS.

I send a hand sketch of a Gooseberry trellis that is in the garden attached to the residence of Mrs. Chrystie, Great Bookham, Leatherhead. The trellis is a most interesting object, especially when the cordons are in fruit, and the owner, who had it formed and planted three years since, is greatly pleased with it. The forming grew out of hearing a County Council lecture on bush fruit culture, in which the growing of cordon Gooseberries in trellis fashion was both advocated and illustrated. The trellis is of strands of stout wire in five lines, and is 5 feet in height.

The strands are firmly secured to stout upright posts. The cordon bushes are about 12 inches apart. Some of the varieties are much stronger growers than others, and it is much better to have varieties planted that make good equable growth, in preference to mixtures of strong and weak growers.

The best of the twenty-three varieties planted, so far as good growth is concerned, are Hepburn's Prizetaker, Green Laurel, Rifleman, May Duke, Whinham's Industry, White Captain, Whitesmith, Red Champagne, Early Sulphur, and Dan's Mistake. Highlander and Lomas' Victory, whilst growing tall, spur badly, the stems being rather bare as shown in the figure. Such varieties are unfit for this particular purpose.

Very good, even, medium growers are Early Kent, Early Green Hairy, Surprise, Railway, and one or two others. These would suit a 4 feet trellis very well. Rather shorter are Goblin, Syon, Leveller, Mount Pleasant, Fearless, Bright Venus, and Forester.

How far this classification may accord with those of nurserymen or others who have the varieties growing as cordons I cannot say, but I give them as found after three years' growth at Bookham.

The summer pruning or pinching the side shoots is chiefly done by Mrs. Chrystie herself, and the plants are pure hard-pinched or spurred cordons. In one or two cases where shoots of about 5 inches in length were overlooked, they were fully fruited, and it was asked whether that fact did not rather favour the bearing of long spurs on the stems. But it was pointed out that once that method became general, the plants would soon be branching stems rather than true cordons. The annual summer pruning resulted in the production of abundant crops, and as the primary object was to secure fine clean fruit, it was very probable that the plants did in each case carry all the fruit they very well could. A mulching of long manure about the roots is found valuable,

Fig. 23.—Cordon Gooseberries.

and liberal soakings of liquid manure are given not only while the fruit is green and swelling, but also after it is gathered, to enable the spurs to plump up stout fruit buds.—A. D.

[A section of the sketch is taken as illustrative of Mrs. Chrystie's Gooseberries as they grow by the side of a path some 20 yards long in her garden. This method of culture affords a maximum amount of fruit from a minimum area of land. The cordons are easy to manage, the fruit easy to gather, and it is found that sparrows do not peck the buds from these cordons with the same pertinacity as they do from bushes, which afford them better foothold. Mrs. Chrystie is to be congratulated on turning the information she gained from a lecture to such good account, and in adding a feature of interest to her garden.]

ROYAL HORTICULTURAL SOCIETY.

August 10th.

Scientific Committee.—Present : Dr. M. T. Masters (in the chair) ; Rev. W. Wilks, Dr. Bonavia, and Rev. G. Henslow, Hon. Sec.

Vine Leaves Defective.—Mr. Ch. Pearson, of Chilwell, Notts, sent some Vine leaves, which appeared to have decayed prematurely. No fungus was present, and their defective appearance was attributable to too high cultivation, guano being freely used with great heat, and too much water, such being quite consistent with their appearance.

Ribes aureum in Fruit.—Dr. Masters exhibited a branch, bearing a raceme of ripe purple-black berries, of this common shrub. Though introduced by Mr. Douglas from California, the fruit has rarely if ever been seen before. It was received from Mr. Veitch.

Chrysanthemum Leaves Attacked by Grubs.—These were received from Mr. Jenkins and were forwarded to Mr. McLachlan, who reports "that the grubs are very young larvæ of the 'Silver Y Moth' (Plusia gamma). It will attack almost anything. They should be destroyed by hand-picking." The caterpillars are doing considerable damage to the Chrysanthemums.

Green-flowered Cross-leaved Heath.—Dr. Masters showed specimens from Kew of this unusual condition. It resembles the "wheat-eared" Carnations sent to the last meeting, and consists of an abnormal repetition of ciliated bracts ; the flower in the centre having been arrested in consequence of an attack by some grub.

Pelargoniums Decaying.—Examples of the varieties "Vesuvius" and "West Brighton" were shown, which had decayed from the collar upwards. It was attributed to too deep planting. They had large roots, and had been apparently quite healthy when planted, some being over two-year-old plants.

GALEANDRAS.

THESE can hardly be classed as popular Orchids, yet one comes across some one or other of the species frequently, so a few notes on their cultnre may not be out of place. They are pretty and interesting plants, but as a rule not showy enough to find favour among Orchid growers generally. All are American plants and like plenty of root and atmospheric moisture, both for the sake of promoting a quick healthy growth, and also with a view to keeping at bay insects, of which thrips and red spider may be set down as their most inveterate enemies. In habit they are erect, the stem-like pseudo-bulbs varying in height according to the species.

In every species I am acquainted with the flowers issue from the top of the pseudo-bulb, and are usually easily recognised by the cylindrical side lobes of the lip, which enfold the column and become spreading in front. Imported plants often arrive in bad order, and are then difficult to establish, but if fairly plump when received they may be treated similarly to Epidendrums of the upright growing distichous leaved section. I was very much disappointed a few years ago when importing a collection of plants of G. nivalis, a species none too common in collections. At first the plants appeared fairly good, and had a certain amount of green fresh foliage, but in the end I only saved two small plants.

Too much moisture at first after the long drying the plants have suffered is often responsible for the loss of many of them; but, on the other hand, unless sufficient is present to plump up the stems, they are almost as badly off as before. When growth begins to show, and it is evident that the roots are going to form, the plants may be potted in almost all clean crocks, only the slightest surfacing of peat fibre and sphagnum moss being allowed. The atmosphere can at this time be hardly kept too moist, but the roots should be on the dry side for a few weeks, in fact until they are freely moving about the compost.

Even for established plants of such as G. Baueri, G. cristata, or G. nivalis, a thick compost is unnecessary, an inch being ample for small plants, and a little more for larger specimens. The best position for them during the growing season is an almost unshaded one in the East Indian house, where the temperature is brisk, quickened by sun heat, and tempered by abundant moisture. Here the plants seem to enjoy life, and may stop until the flowers begin to show colour, when a little cooler position is advisable both to conserve the flowers and form a sufficient check to prevent their growing again, for it will be noticed that the spikes of bloom usually show when the pseudo-bulbs are about finished.

During late autumn and winter keep the plants at rest if possible, by arranging them in a house with a minimum temperature of about 50°, the atmosphere and roots at this season being kept much drier. At least once during the growing season, and also once while at rest, the plant should receive a good cleaning, every leaf and stem being thoroughly sponged. Gentle applications of the vaporising fumigator are also of assistance to this class of plant, as well as light sprinkling with tepid soft water during hot weather. Clean rain water, as I have often pointed out, is one of the very best insecticides, and, unlike many others, cannot possibly do any harm.

Galeandra is not a large genus, and those species mentioned below may be considered as the cream of them, several others being known, but either indistinct or small and insignificant. G. Baueri grows about a foot high, but the bulb does not thicken over the whole length. The blossoms appear in summer on drooping peduncles, the sepals and petals being olive green, the lips white on the outside where it enfolds the column, the front a pretty bright purple. There are several variations from the type, the best and most constant being G. B. lutea, in which the green almost gives place entirely to yellow, and the front of the lip is also brighter. G. cristata is a pretty dwarf-growing form, not unlike G. Devoniana in habit, but not half the size. The flowers, too, are smaller, and a pretty combination of rosy pink, white, and deep purple.

G. Devoniana is more generally grown, I think, than any, and although it does not attain the height under cultivation that it is said to naturally, it is a useful and free-flowering plant. The sepals and petals are purple in the centre, with a decided margin of greenish white all round each. The lip is striped with bright purple on a pure white ground, and much resembles that of G Baueri in shape. Sir Robert Schomburgk first discovered this plant near the Rio Negro in 1840. G. flaveola is a native of Venezuela, whence it was introduced about ten years ago, and has pretty yellow flowers, with a blackish purple centre. G. nivalis is one of the prettiest of all, the brownish-tinted outer segments showing nicely against the white lip, which latter is blotched with violet purple. Other kinds are G. Claesi, G. Dives, G. Harveyana, and G. minax, all more or less distinct from those described.—H. R R.

THE WHEREABOUTS OF VINE ROOTS.

MOST of us think we know where to find the roots of Grape Vines under our charge, but we meet with a surprise occasionally. The roots are naturally supposed to be located in the borders formed for their special benefit, and if they cannot possibly get out it is there where they will be found. As it happens it must be a very good boundary wall on a well made concrete floor to the border to prevent Vine roots finding their way through, and it is very certain ordinary brick and mortar walls are not often equal to confining them. In the case of a large span-roofed vinery of some note, the side walls were arched in the usual way with a view to forming an outside border when that inside the house was well filled with roots. The archways were, therefore, temporarily filled in with bricks and mortar, and owing to the inside border having been thought equal to the requirements of the Vine roots, the arches had never been opened.

Although very fine crops of Grapes were produced by the Vines for many years in succession (house and Vines are not less than twenty-five years old) there was yet something unsatisfactory about them—or more shanking going on than those in charge cared to admit. About five years ago a deep trench had to be cut for a water pipe about 20 feet from the vinery, and it was then discovered that Vine roots were spreading in all directions, particularly down in the clayey subsoil. A few roots had first found their way through crevices in the brickwork, and liking the new soil spread rapidly. That portion of the main roots between the brickwork was found to be flattened out in an extraordinary fashion, but beyond the wall they swelled to a great size. The gardener in charge preferring to have full control of the roots, cut away the whole of those through the wall, and took precautions to prevent others from also finding their way out. As this was done in the autumn, before the leaves were yellow, the Vines had time to form more roots in the inside border, and there were no signs during the next season of their having had their "toes cut" in such a drastic fashion. On the contrary they have steadily improved since, and at the present are carrying heavier and better crops than was ever seen on them before.

About the same time I was having a somewhat similar experience. In my case the roots had found their way through crevices in an ordinary brick foundation wall, crossed a gravel path, and taken possession of Asparagus beds beyond. Apparently these were more to their liking than the inside border—at any rate, I had good reason to be well satisfied with the crops of late Grapes those Vines produced, and under the circumstances decided not to interfere with these foraging roots. As a rule Asparagus beds are more liberally treated than Vine borders, the surfacings of manure, warmth, and moisture, coupled with non-disturbance, keeping Vine or other roots that steal into them active near the surface. Once, and only once, did I regret having to a certain extent lost control of the Vine roots. After an unusually dry autumn we had a deluge of rain, with the consequence that a rush of sap caused the rupturing of many berries. This would not have happened had we watered our Asparagus beds in August and September, for the bursting could not be prevented by free ventilation accompanied by fire heat.

Here, then, are two instances of Vine roots having escaped from the borders proper—one with marked ill effects accruing to the Vines, and the other with benefit to the Vines rather than otherwise. Others might be cited of accidental discoveries of the escape of roots, some with good and some with bad results. This capability of being able to forage for food has doubtless saved the lives of innumerable Vines, also serving to keep them in a fairly profitable condition. Planting them in inside borders, and overlooking the fact that they will do no good in dust-dry soil, has led to many failures, and the number would be far greater if the roots were unable to break loose.

Vine roots are supposed to have a strong predilection for outside borders, and as I have shown, and most Grape growers have discovered, they will leave or cease to increase in an inside border if they have access to moist soil outside. Acccording to my experience they object to restriction nearly as much in outside borders as they do in those under cover. What they revel in is fresh soil, naturally preferring good garden ground or an Asparagus bed to the stale close soil of an old border.

To make matters worse, inexperienced or thoughtless persons

begrudge the small breadth of outside border originally formed for the Vine roots, and must needs crop this with Vegetable Marrows, Tomatoes, and such-like, while in some cases the lady of the establishment insists upon the Vine border being covered with flowers. The very act of digging has the effect of driving the Vine roots down into the cold subsoil, and cropping the surface further aggravates the evil. If the roots are principally 12 inches or more below the surface sappy growth followed by wholesale shanking of berries is the result, the Vines getting into a most unsatisfactory condition, and it is either during or after cold wet summers that the worst progress is made. On the other hand, if the roots are by good management kept near the surface, only to be allowed to suffer from drought in a dry season, red spider and faulty colouring are the worst evils resulting.

When we know the roots are principally in the surface soil the least we can do is mulch early and water occasionally during dry weather. Unfortunately the difficulty in far too many cases, notably where amateurs are responsible for the treatment given, is to discover where the roots really are. They may be foraging on their own account, but if Dame Nature is unkind it is a poor look out for the Vines. Last season many Vines, with their roots nobody knows where, fared badly, and so they have again this season, and if my advice is taken something will be done next autumn towards remedying the original mistake of losing touch with them.—W. IGGULDEN.

MELON GROWING TROUBLES.

MELON growing is popular with the majority of gardeners, probably because the plants give a quick and ample return for the labour bestowed upon them. Well-grown fruits have also a noble appearance upon the dessert table, and their rich melting flesh is both delicious and wholesome in warm weather. It is really wonderful what a number of Melons are grown in some gardens where no special provision is made for their culture. Pits, frames, and houses of various descriptions are pressed into service, because they are free from their usual occupants, just long enough to give the opportunity of growing in them what may be termed a "catch crop."

As a matter of course, when grown in this way their culture is often attended with difficulties, but in many instances these may to a great extent be overcome by the exercise of a little ingenuity. I have grown many fine crops in cold pits, and in dry seasons like the present they usually succeed well in such positions; but should long periods of dull or wet weather prevail while the fruit is swelling and ripening it is no easy matter to bring the plants through safely. Ventilating is then an important matter, for unless the most is made of the little sun heat we get at such times, by closing as soon as the sky becomes overcast, canker and rot speedily play havoc with them. On the other hand, if an insufficient supply of moisture is given at closing time during bright weather red spider puts in appearance, and the energies of the plants are crippled. If, however, errors are avoided, paying crops of Melons may be grown in frames. Useful hints are conveyed in the following paragraph.

Plant on slightly raised mounds, keep the thinning and stopping of shoots regularly attended to; dress all cuts and wounds with a mixture of lime and soot, to dry up the sap quickly, and thus avoid risk from rot; in giving water at the roots choose, if possible, bright weather, and do not wet the soil for a couple of inches around the main stem.

Turning to Melon culture in heated houses and pits, the difficulties connected with the work are not usually so great; still, they are sometimes considerable. The plants revel in very high temperatures provided the proper balance between heat and moisture is maintained, and that the hot-water pipes are not situated too close to the main leaves and fruiting shoots. Unfortunately, however, many gardeners are obliged to grow the bulk of their Melons in houses where the latter conditions prove a great stumblingblock; such houses are often old Pine stoves, now used for growing both stove plants and Melons. Over a rather narrow walled-in bed at the front we sometimes find four hot-water pipes, so placed as to make it difficult to plant Melons on either side of them without the leaves of the main stem touching the pipes, and when trained to the trellis overhead they are little more than a foot from the pipes.

This state of affairs would perhaps be of little consequence if the heat could be regulated at will, but in many instances the Melon houses are in a long range, not heated on the modern principle of working each house independently of the others. It thus happens that the heat required for a particular house has first to pass through another, where a less amount is required. Undesirable though this state of affairs is, a combination of circumstances makes it impossible to arrange the crops growing in the various houses in a more suitable way. The difficulty we have to face is that of growing Melons in a house where both stems and foliage are far too close to hot-water pipes too highly heated, conditions especially favourable for the production and spread of that dread pest red spider.

The task of growing good Melons under such conditions is not, however, an impossible one. There are two ways out of the difficulty which I have practised successfully at different times. The first is this: remove all side shoots from the Melon plants until they have grown beyond the point at which the hot-water pipes are immediately beneath them. It simply means giving each plant a greater length of main stem and obtaining the crop from the upper portion. This causes a delay of about a week in securing the crops. The advantages, however, greatly overbalance this drawback, as the shoots bearing fruit can be kept perfectly free from red spider, and if the leaves on the main stem near the pipes become badly attacked they can easily be dressed with an insecticide, and when plenty of growth has been made about them removed altogether. If the wounds are then dressed with a mixture of powdered charcoal and lime there will be no danger of rot setting in at points of removal, because the great heat near will speedily harden the wounds made by pinching or cutting away the leaves.

The other plan is as follows:—Encase the top and front of the hot-water pipes with boards; the dry parching heat cannot then find its way directly to the leaves, but circulates from the pipes into the body of the house, at a point where the trellis is a good distance from the pipes. Another advantage gained by following this plan is that frequent syringings can be given without raising the great amount of vapour which would result from the practice whenever the pipes were very hot. This alone practically solves the difficulty, for Melons enjoy almost any amount of fire heat, provided plenty of moisture is given as well.

When Melons are grown under the conditions just named every particle of the plant must receive a thorough syringing at closing time during bright weather while the fruit is swelling. Should the weather be very bright the syringing ought to be repeated two hours later. At night, when the fires are banked up, a thorough damping of the floor of the house should be resorted to, and whenever the pipes at that time are quite hot the plants thoroughly syringed as well. Treated in this way, and given good attention in other respects, good crops may invariably be grown, even under such trying conditions. The appearance of red spider must at once be checked by sulphuring the pipes, and if possible raising the temperature of the house to 90° by fire heat. Before this is done, however, the condition of the soil about the roots ought to be clearly ascertained, and if this is in the least dry, give water.

When Melon plants are swelling heavy crops of fruit, they do not, as a rule, produce young growths very freely. This must be constantly borne in mind, and a few shoots left unstopped whenever the plants are gone over, as I am convinced that a frequent cause of collapse is the removal or stopping of every shoot on a given date. If this is done at a time when the fruits are swelling rapidly, they frequently fail to make further growth, and, as a natural consequence, to produce well-flavoured fruits. Canker and bacterial diseases are extremely difficult to deal with when once established, but I have no hesitation in saying that in almost, if not every instance, they are brought about through mistakes in management.—H. D.

HARDY FUCHSIAS.

THE use of the Fuchsia as a greenhouse plant is perhaps appreciated to its fullest extent; the value attached to some of the members of the same genus, though, as hardy shrubs does not appear to be so generally recognised. Although some of the species, together with the bulk of the varieties, cannot be said to be sufficiently hardy to withstand more than a few degrees of frost without disastrous results, there are still several which come safely through the ordeal of an ordinary English winter.

Of these some of the most noteworthy are F. globosa, F. gracilis, and F. macrostema, species natives of Chili; and F. exoniensis and Riccartoni, hybrids. The flowers of all resemble each other very closely in colour, in all cases the calyx being red and the corolla purple. The habit of each plant, however, is distinct, and each one has its special advantages. For hardiness and free flowering qualities none can beat Riccartoni. It does not make such long growths as some of the others, but they are held in a more upright position, showing off their numerous showy blossoms to the best possible advantage. In very severe winters the growths are usually killed to the ground, but as spring comes they quickly make fresh shoots. In places, however, where very severe frosts are not experienced the old wood, save at the tips, is not injured; consequently bushes several feet high are made.

For growing in the front of shrubberies these are excellent plants, the flowers being produced at a time when flowering shrubs are becoming scarce. A very pretty effect can be produced by planting F. Riccartoni rather thinly in a bed and filling up the spaces with Galtonia candicans,

the white flowers of the latter contrasting well with the former. In places where flowers are wanted in quantity for decoration the full length branches of these will be found acceptable.—W. D.

REFLECTIONS IN THE FLOWER GARDEN.

It is quite evident to people of cultivated taste how badly our flower gardens are planned from the standpoint of colour effect. There have been many declamations against summer bedding. But as our summers are so short, we ought to endeavour to make them as brilliant as possible, and this can be done if, instead of so much imitation, we behold aright the way Nature blends her colours in the rainbow, the autumn sunset, the plumage of birds, and in innumerable other ways. A knowledge of how the artist mixes his colours would aid us; but observation and reflection on the beautiful combinations of colours we may see around us in Nature and Art is the true standpoint, and I think I cannot do better than record one of the most effective pieces of bedding I have seen this year.

They were long borders in front of a noble range of glass houses at a fine old place in the south of Ireland, where the climate is more uniform and moister than in England. The planting had been done in straight lines, and this was the only detriment of what might have been pronounced a finished picture. The borders had been stocked early, and contained strong, healthy plants.

There were two borders; the first had a permanent edging of Gentiana acaulis, and the other plants were in continuous lines from front to back in the order named. A line of intense blue and profusely flowered Lobelia, white Viola, yellow Viola, Centaurea candidissima, Tropæolum Fire King (a mass of brilliant flowers), "Geranium" Crystal Palace Gem (flowers kept picked off), Iresine Lindeni, Flower of Spring "Geranium" (flowers kept picked off), and Lobelia cardinalis. The other border was also edged with Gentiana acaulis, next line white Lobelia, and others in the order named as follows:—Yellow Viola, white Viola, red Tropæolum, Sophia Dumaresque tricolor "Geranium," Iresine Lindeni, Flower of Spring "Geranium," yellow Calceolaria (robust and profusely flowered), and Lobelia cardinalis.

These borders were each 120 feet long, and in the centre between the two were two connection borders, intersected by cross walks filled with grand clumps of Alstrœmeria aurantiaca, A. chilensis, and A. aurea, also masses of Delphiniums and Gladiolus The Bride, and clumps of Sweet Peas represented Invincible, scarlet; Princess May, a lovely shade of pale blue; Lady Beaconsfield, a combination of salmon, pale rose, and primrose; Orange Prince, orange and scarlet; and Purple Prince. These were in separate clumps, and a point observed here was the avoidance of stakes too tall. They were not allowed to reach higher than the bottom of the flower stem proper, as, for instance, Delphiniums 3 feet from the ground instead of 5 feet, as is often the case; for Alstrœmerias 18 inches would be ample. By observing this rule stiffness and formality will in a great measure be obviated. The removal of the flowers from the bedding "Geraniums" in the borders mentioned is to prevent two shades of red spoiling the harmony.

Another border, in a different part of the same garden, was planted with circles, each of two colours, in harmonious contrast. They consisted in the order named of yellow and brown Calceolarias, French Marigolds and Perilla, blue Ageratum and Crystal Palace Gem "Geraniums," Sweet Alyssum, Mesembryanthemum, and Bronze "Geraniums."

I have observed the plan practised in the aforementioned borders followed in both public and private gardens—namely, the breaking up of what would otherwise be crude mixture by the use of white flowered or white foliage plants. But it has frequently been in what I shall call the alternating system, every alternate plant in the beds being white. This, although it prevents the clashing of inharmonious colours, is, to say the least, indistinct, confused, and heterogeneous. The ideal flower garden should have as much variety as possible, ruled, of course, by its size. Too much variety in a small space would be out of character.

But all flower gardens ought to have not only beds in which colour is the chief characteristic, but also those in which tall, noble, graceful, and majestic plants would display their forms, to break the flatness so frequently seen where only the ordinary flowering and low-growing coloured foliage plants are found. Then, also, with colour and form, plants emitting fragrant odours should not be forgotten. If our beds were circles, instead of other fanciful and geometric shapes, they would be easier to plant, and more effective in the display of colours. Beds of one colour, or two colours forming a harmony, instead of mixture which requires nice discernment and thought to be pleasing.

It is important to remember that all Nature's variety results from the combinations of the three primary colours, red, yellow and azure. From these with the addition of black and white, 800 different shades and tints are formed. To oppose two primary, as red and yellow, or red and blue, is crude and inharmonious. The same effect is caused by opposing a secondary colour with a primary from which it is formed, as yellow and scarlet (scarlet being formed by the mixture of red and yellow). So to have a pleasing harmony, let us have a primary opposed by a secondary formed from two other primaries, as yellow opposed by purple (which is formed by the mixture of red and blue). A combination of relative hues is pleasing and correct, as orange and scarlet, both formed from red and yellow, or crimson and purple, both formed from red and blue.

In the planting of beds with tall, graceful and noble foliage plants, I advocate only one variety in a bed, planted thinly so that their individual character may be seen, with a groundwork of some low-growing creeping plant to cover the earth. In addition to the many half-hardy and subtropical plants of ornamental form, permanent beds might be made of many plants seen only in herbaceous borders, as, for instance, the Plume Poppy (Bocconia cordata), Hyacinthus candicans, Tritoma Uvaria, Polygonum sachalinense, Sedum spectabile, Echinops, Eryngium amethystinum, Funkia Sieboldi, Funkia ovata variegata, Fuchsia Riccartoni, Hollyhocks, Rudbeckia hirta, Rudbeckia Newmani, Acer Negundo variegata, Hydrangea paniculata grandiflora, Farfugium grande, beds of Marguerite Carnations, and such free-flowering sorts as Raby Castle, Duchess of Fife, and Redbraes Picotee, and Mrs. Sinkins Pink; also plunged in pots, Lilium longiflorum, Lilium lancifolium rubrum, and the varieties of Lilium speciosum for groundwork or edgings, many hardy plants as the blue Shore Grass (Elymus arenarius), Dactylis glomerata, Cerastium tomentosum, Heuchera Richardsoni, Sedum glaucum, Sedum Lydium, Herniaria glabra, Antennaria tomentosa, and common Musk.

Of course, the use of tall and noble foliage plants in the flower garden must be regulated according to the size of the same, as proportion and balance is to be observed in Nature and Art, avoiding formality, stiffness, rigidity, and disjointed colour. Flowering Cannas, Fuchsias, and Begonias will be most effective in beds of one variety.—F. Street.

BRIEF NOTES ON ALPINE FLOWERS.

(*Continued from page* 121.)

Acæna argentea.

The Silvery Acæna in its flowering season suffers in comparison with the rosy-spined one by reason of its flower heads having no special colouring to give them beauty in the eye of the casual observer. It is not, however, in these that its charm exists, but in the silvery appearance of its leaves. These are not like bright polished silver, but are, as it were, dulled over so as to give the plant a more subdued tone of beauty. The leaves are larger than those of A. microphylla, which was mentioned on page 120, and the whole plant is more rambling in its ways. This is, in truth, its principal failing, as if placed among choice plants it is apt to overgrow and destroy them.

The best positions for the Silvery Acæna are on a sloping bank, hanging over a rocky shelf, or among the steps of the rock garden. It appears to flourish better in a dry place than A. microphylla, and to require less moisture. Another feature is its apparent indifference to sunshine or shade from its rays. A. argentea is very readily increased by means of division. It is a native of Chili, but is quite as hardy as its New Zealand relatives.

Bellis rotundifolia var. cœrulescens.

A long name for a little plant is this, and it is little wonder that those who grow it are content with calling it simply the "Blue Daisy," or, if more inclined to use Latin names, "Bellis cœrulescens." The more correct English name would be the "Bluish Daisy," not only as more nearly approaching the word cœrulescens, but also from the colouring being so pale that it cannot be called blue. In some soils the bluish tint is more pronounced than in others. The plant is a neat little one, with roundish green leaves and pretty single Daisy-like flowers. It comes from Algeria, and, like a good many other plants from Northern Africa, is not absolutely hardy in a good many gardens. In light soil and mild districts it is not only truly perennial, but increases very quickly at the root, so that it soon forms a good-sized plant.

Seeds can be obtained from some seedsmen, and the question of the possibility of increasing the depth of colouring in the flower by means of selection is one worthy of consideration by some amateur who has the time and space requisite. It might, and probably would be, possible in the course of a few years to raise and fix a deeper tint, so as to make the name of "Blue Daisy" an accurate description of the colour of the blooms. Six inches is its normal height, and this is seldom exceeded on suitable soils. B. r. cœrulescens grows freely in sandy soil on a sunny rockery. In colder districts it may be preserved in a cold frame in winter.

Campanula alliariæfolia.

This Bellflower is more frequently grown as a border plant than as a rock garden one. It is, however, better adapted for the rockery than the border, as its Foxglove-like habit looks more effective on an elevated position than on the level. It is not often found mentioned in gardening books, but is to be met with in gardens occasionally, sometimes under the name of C. lamifolia. The name of C. alliariæfolia is the one under which it is grown at Kew, and is that applied to the plant by Willdenow. It is a native of the Caucasus and adjoining districts. It does not appear to possess a trivial or "popular" name, and "Alliaria-leaved Bellflower" is not likely to commend itself to those in search of a pleasant name for the plants they care for. If I might suggest one, it would be the "Foxglove Bellflower," although this has the demerit of leading some to think that the flowers are purple instead of white.

C. alliariæfolia grows from 12 to 18 inches high, and has leaves rather resembling those of the Foxglove in general appearance, but in form more approaching those of the Lamium, whence, one would suppose, the name Lamium-leaved has been applied by some. The spike of pretty, long, bell-shaped flowers droops forward, and, perched well up on rockwork, is very attractive to many. This Bellflower is perfectly hardy, and a true perennial. It may be raised from seeds, and is also increased by division of the roots. Its habit is good, and as it gives little or no trouble, it deserves a place in more gardens than at present.—Alpinus.

(To be continued.)

Notes & Gleanings

EVENTS OF THE WEEK.—The shows that are fixed for days in the forthcoming week are numerous. Some of the most important are the National Co-operative at the Crystal Palace on Friday and Saturday; the summer show at Perth on the same dates; the R.H.S., and the Drill and Brighton on Tuesday; with Sandy on Thursday, 26th inst.

—— WEATHER IN LONDON.—Immediately after our last issue went to press on Wednesday rain fell very heavily for some time, as it did again on Thursday, when it was accompanied by thunder and lightning. Friday and Saturday were dull with occasional glimpses of bright sunshine and light showers, while on Sunday rain fell for several hours. No rain fell on Monday, but there was a slight drizzle on Tuesday morning. Wednesday was fine.

—— JULY WEATHER AT HODSOCK PRIORY.—Mean temperature, 60·9°. Maximum in the screen, 80·9° on the 30th; minimum in the screen, 38·5° on the 12th; minimum on the grass, 31·1° on the 8th. Two frosts on the grass. Sunshine, 220 hours, or 44 per cent. of the possible duration. Rainfall, 0·57 inch. Rain fell on six days. A fine bright month with warm days and very little rain.—J. MALLENDER, *Worksop*.

—— DESTRUCTION OF WILD FLOWERS.—At a recent meeting of the Essex Field Club, held at Easton Lodge, the residence of the Earl and Countess of Warwick, to consider the best methods of protecting our native flowers and annuals from extermination, Professor Boulger proposed, and it was carried, "That in view of the danger of extermination threatening many beautiful, rare, and interesting plants, all lovers of Nature should do their best to avoid this danger (*a*) by abstaining from wholesale collecting, collecting for merely individual private collections, needless rooting-up of specimens, attempting to cultivate wild specimens of refractory species, and purchasing such wild specimens from itinerant or other dealers; (*b*) by endeavouring to persuade others, especially school children, cottage gardeners, and dwellers in large towns, to a similar abstention."

—— DEATH OF SIR ISAAC HOLDEN, BART., M.P.—The death of this remarkable man on the 13th inst., reminds us of a pleasant visit we once paid to Oakworth, when the erection of his great winter garden, which is said to have cost £120,000, was just completed. His progress in life has been extraordinary. His father was a working miner, and his son, who was born eight years before the battle of Waterloo, began to earn his own living at the age of ten, in 1817. He worked in a cotton mill, and educated himself at night. He became a school teacher, inventor, and millionaire. His description of inventing the lucifer match is worth recording Here is the story:—"I found that the use of a flint and steel cost me a good deal of time and trouble, and as I was at the period lecturing on chemistry to my classes, I cast about me for some substitute for the flint and steel. In this way—in the year 1829—I hit upon the lucifer match. I lectured to the boys upon the subject and showed them how the light could be obtained. Mr. Greathead, the proprietor of the academy in which I lectured, urged me very earnestly to go to London and patent the invention, and he told me that a chemist (a friend of his who sent his sons to his academy) would furnish the capital required to take the patent. I positively refused to patent it, and told him that his friend, the chemist, was therefore at liberty to manufacture the matches. The way in which the matches afterwards gained a hold with the public undoubtedly turned my attention to inventions, and I regard this one discovery as the germ of all my after labours in the way of original discovery." His description of his habits and regimen is also noteworthy. "For years," said Sir Isaac, a year or two ago, "I have never walked less than eight miles a day, wet or fine; indeed, I seldom ride when I feel I can walk. I have an infinite belief in fresh fruit so far as diet is concerned, and for years I have breakfasted entirely on baked Apples, Bananas, Oranges, Grapes, and biscuits made of Banana flour and butter. I am no believer in suppers, and I think that elderly people should strenulously avoid farinaceous foods as a rule. When I do take any food at night, it is fruit always. I live largely by rule, and never felt better than I do now—but I have never adhered to such rules in an oppressive degree. One meal usually consists of animal food alone, and two meals of fruit and vegetables." Sir Isaac's baronetcy was granted in 1893.

—— ROYAL HORTICULTURAL SOCIETY.—The next meeting will be held on Tuesday, August 24th, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 P.M. A lecture on "Plums," by Mr. A. H. Pearson, will be given at three o'clock.

—— THE KING OF SIAM AT CHELSEA.—We are informed that on Sunday morning his Majesty King Chulalonkorn, accompanied by Prince Sanpasaht, Baron Sunthorn, and other members of his suite paid a visit to Mr. William Bull's establishment, King's Road, Chelsea, and inspected the new and rare plants that have been collected from all parts of the globe.

—— BEAUTY BY THE WAYSIDE.—The wild shrubs which skirt the waysides have a beauty beyond that of the cultivated exotics in spaded gardens; they cover the nakedness of stone walls with foliage and flowers; they give shelter to the birds and fruit for them, which is also a luxury to the children; they protect adjacent farm lands from winds, and constitute the most interesting embellishment of a rustic farm.—WILSON FLAGG.

—— GARDENING APPOINTMENTS.—Mr. H. W. Pitcher, head gardener to the late Mrs. Dunnage, Allbury House, Surbiton, has taken over the managership of the Surbiton Nurseries. Mr. R. Wardman, general foreman at Kirby Hall, York, the residence of Sir Henry M. Meysey Thompson, Bt., M.P., has succeeded Mr. W. Wallis as head gardener. Mr. C. Cawley, for upwards of two years gardener to W. M. Tidy, Esq., Lynton Croft, Caterham, has gone in a similar capacity to G. A. Touch, Esq., Eaton Tower, Caterham Valley.

—— BOSCOMBE HORTICULTURAL EXHIBITION.—The above opened on Tuesday. There were rain storms from 8.30 A.M. till twelve noon, but fine, with rather strong wind after. Some grand exhibits were staged in the open division. Mr. J. Cypher was first for the 200 feet group and for twelve stove and greenhouse plants; Mr. T. Wilkins second, and Mr. W. Vause third in each class. All were grand exhibits. There were good entries in the fruit classes, but unfortunately some of the produce was damaged in transit. Only second and third prizes were awarded in the collection of nine dishes. C. H. M. Ricketts, Esq., second; Sir J. W. Kelk, Bart., third. Three bunches white Grapes.—J. W. Fleming, Esq., first; Sir J. W. Kelk, second; and Lady Ashburton, third. Three bunches black Grapes.—J. W. Fleming, Esq., first; Mr. F. Ricardo, second; and Sir Wm. Pink, third. Collection of nine dishes of Vegetables.—Mr. T. Wilkins, first; Sir J. W. Kelk, second; C. H. M. Ricketts, Esq., third; and Marquis of Northampton, fourth. A fuller report will appear next week.

—— PRESENTATION TO MR. O. THOMAS.—On Saturday last an interesting ceremony took place at Frogmore, when the foremen and young gardeners presented Mr. Thomas, Her Majesty's head gardener, with a handsome silver waiter and an address of congratulation on his silver wedding day. The movement originated with the foremen, who wished to acknowledge in some way, as a body, Mr. Thomas' kindness and courtesy, also his encouragement and assistance to the young men. In a few days a good sum was subscribed, although the list was limited to the permanent staff of foremen and the young gardeners who have served under Mr. Thomas since he was appointed to Frogmore in 1891. It was intended as a surprise, and no intimation reached the recipient until the day previously, when he was requested to meet the foremen in the reading-room. On Saturday afternoon the proceedings commenced by the party being photographed in a group, with Mr. Thomas in the centre, followed by a repast. After luncheon Mr. Thomas proposed the health of the "Queen, and God bless her," which was heartily responded to by the company standing. Mr. Chennell, as Chairman of the Committee, then introduced the subject for which they had assembled, and called upon Mr. Edwards, Hon. Sec. to read the address, which, after heartily congratulating Mr. and Mrs. Thomas on their silver wedding, stated how gladly they availed themselves of the opportunity to testify to the courtesy and kindness of Mr. Thomas to his men, and of the respect and esteem in which he was held by them. It concluded by hoping that the same good relations might exist between them for many years to come, and begging his acceptance of a silver waiter as a slight memento of that happy occasion, with the names of the donors. Mr. Marr, the oldest employé, then handed the waiter to Mr. Thomas, beautifully engraved with the following inscription: "Presented to Mr. and Mrs. Thomas by the foremen and young gardeners, past and present, of the Royal Gardens, Windsor, as a token of respect, and with sincere congratulations on their silver wedding day, 14th August, 1897." Mr. Thomas, having suitably responded, proposed the health of the foremen.

—— Society of Jersey Gardeners.—There are almost sixty classes particularised in the schedule of the autumn show to be held under the auspices of the above Society on Thursday, November 5th, in the Oddfellows' Hall, Don Street. Some are for Chrysanthemums, others for Orchids, Primulas, and floral decorations. We do not anticipate that the English growers will have a try for the prizes, as for a group of Chrysanthemums 10 feet by 6 feet only 12s. 6d. is offered as the second prize, the first being named as "special," whatever that may mean. The same prizes are offered for twenty-four Japanese distinct. If any reader would like further particulars, let him write to the Hon. Secretary, Mr. J. M. Gibbs, Spring Bank, Valley-des-Vaux.

—— A Spin to Southwell.—Until recently I had not had the pleasure of paying a visit to the Southwell Nurseries. A cycling friend, who is a lover of Roses, wanted to see Mr. Merryweather's, and I wanted to see Bramley's Apple at home. We saw the Roses in different shapes and sizes, the best new and old varieties, in the best of health, but were a little too late for the flush of show blooms. For the first time I saw "Bramleys" in all stages and forms, from maidens to bearing standards, sturdy and bold. Though this Apple has spread far and wide, it is not so well known as it should be in the western counties, where growers as a rule are so loyal to the "locals." Having had enough walking for one afternoon, we took a rest until it was time for us to get awheel again.—John Ettle.

—— Growth Force.—The growth force of trees is something astounding. Roots have been known to overthrow stone walls by their continuous growth. In rocky woods one may frequently see trees growing in the clefts of rocks; and, although the cleft may have been but a few inches wide when the tree started into life, so great has been its growth force that, in maturity, the rock has been pushed apart as widely as the width of the trunk itself. Trees have been known to mislead surveyors. Everyone knows that a tree trunk, once formed, never grows longer; and yet survey marks made on trees have been known to be considerably higher when the tree grew older than when first made. In these instances the trees have been growing on flat rocks, and, by the increased thickening of the roots, these huge trunks have been lifted by the pressure of the roots upon the rock.—("Meehan's Monthly.")

—— A Tourist Guide to the Continent.—Acting under the authority of the Great Eastern Railway Company, Mr. Percy Lindley has prepared and published another of these most useful books, which ought to be in the possession of every continental traveller. The information is conveyed in a clear readable manner, maps and smaller illustrations of notable places embellishing the text. The chapter on cycling routes in Holland, Belgium, and Germany is excellent, and should be of the greatest assistance not alone to wheelmen, bnt to all others who propose visiting either or all of these countries. The book is published at 6d., a price which the large map alone is easily worth. This embraces Norway, Sweden, Denmark, Prussia, Holland, Austria, Hungary, Bavaria, Wurtemberg, and Switzerland, with clear indications how towns in these countries may be reached from London viâ Harwich and the Hook of Holland. This publication may be had from the office, 30, Fleet Street, or from the Continental Department, Great Eastern Railway, Liverpool Street Station.

—— Bramley, Surrey. — The annual local exhibition at this place was held, as is customary, in the beautiful park attached to Colonel Ricardo's residence, and the really lovely gardens and houses were all thrown open to visitors to the show without reserve. The competing products were chiefly from cottagers, and were, as is customary here, of excellent character. The show was greatly helped by various fine honorary exhibits, including a splendid collection of cut flowers, Roses being prominent, and hardy herbaceous things in rich profusion, from Messrs. J. Jackman & Sons, Woking. Mr. H. Shoesmith, also of Woking, sent various handsome Cactns Dahlias that attracted much attention; and Mr. W. Virgo of Wonersh had single and double Petunias, Roses, Dahlias, and large Cucumbers. A very fine and exceedingly gay group of plants, though rather too formally arranged, was set up by Mr. A. J. Joy, gardener to Mrs. Courage of Bramley. Other good groups came from Mr. Heather, gardener to E. R. Fisher Rowe, Esq.; Mr. Dyer, gardener to Cowley Lambert, Esq.; and Mr. Callaway, gardener to R. Worley, Esq. Cockscombs, well grown and of fine form, were seen in all these groups. Through the kindness of Col. Ricardo, the drum and fife band of the Grenadier Guards was brought down from London to play, and there was also a fine military band from Aldershot. Mr. Paddon, the gardener, left his beautiful products to be seen in the houses.

—— Earlier Opening of Kew Gardens.—Replying to a deputation on this subject, Mr. Akers-Douglas is reported to have said that the *raison d'être* of the existence of Kew Gardens was the valnable scientific work it did, and he could not be expected to do anything in the way of extending the hours during which the gardens were open to the general public if it would interfere with that work. The financial question did not weigh with him at all, for if he were convinced that the interests of science would not suffer by the earlier opening he should endeavour to persuade the Treasury to grant any extra money required. The sole question for consideration was whether the interests of science could be combined with the desire of the people for the earlier opening, and he regretted to say that the scientific men, whose opinions he had obtained, were entirely opposed to the proposal. From a scientific point of view the experiment had not been a success in Edinburgh, and they had no reason to anticipate any better result at Kew.

THE DECAY OF GARDENING.

The ferment behind that hideous phrase "up to date" has set its seal upon gardening, and year by year it becomes more apparent that the days of the high-class cultivator are numbered. I do not say that he views his own extinction with favour, but none the less the times are crowding him out, and his place is being taken by the "smart" man of a later and more feverish generation. Old gardeners do not realise the change that is being gradually brought about, because their employers' means are too limited to permit of their going to shows and other horticultural gatherings as they used to do; but when by chance one of them finds himself back amongst what should be the old scenes, he is shocked and dismayed at the signs he sees of the rapid deterioration of the craft.

The "old fossil," as he is now contemptuously termed by the young bloods of the profession, has a hard fate before him. To business men who make money quickly such old-fashioned ideas as mutual respect and trust between master and man are unknown. They come into the garden as they go into their counting-houses, and reckon up their gardeners as they reckon up their clerks—namely, as so much flesh and blood that is capable of a given amount of labour, worthy of a given amount of remuneration, and eventually, when the capability for performing that given quantity with the same expedition as they did in their younger days is gone, to be sent off with as much compunction as would be displayed in getting rid of a worn-out cart horse. The times have changed, and with them are changing that mutnal consideration and esteem which have led to so many triumphs for British horticulture.

A week or two ago I came upon a particularly instructive example of the new order of things. Fifty years ago an excellent gardener ruled on a large estate in the south of England, the name of which I could give if any good end would be served by it, which I strongly doubt. He trained his young men, amongst whom was one of his sons, in the same way as he himself had been trained before them. In due course the son succeeded the father, and worthily upheld the credit of his name. But hard times came for the noble employer, and eventually the place was sold to a trade king. The gardener was solicitons of following the fortunes of his old master, who, however, could do nothing for him, and eventually, at the earnest request of the trade king himself, he stayed on. For several years, indeed until the young gardener had in his turn grown grey, no fault was ever found with him, but within a week of his sixtieth birthday he was given a month's notice to leave, and in his place was installed an "up-to-date" gardener, a young man who, on the strength of a year or two in Kew and a year or two more in a large Orchid emporium, was considered capable of managing an extensive baronial garden.

It is this sort of thing that brings about the decadence of gardening, signs of which are now so abundant. Let us turn our attention to Grapes. Where are the magnificent examples of culture that we met with years ago? Few, I think, have been more constant visitors to the principal exhibitions during the last two decades than myself, and all too palpable it is to me that the standard of excellence is steadily declining. There must be many who sigh with me for a sight of the Grapes that Mr. Henderson used to show in the days that are gone. We do not see their like now, go where we will. Year after year that great cultivator staged splendid specimens of Black Hamburgh, the worst of which—if I may use such an expression where all were of such a high order of excellence—was in advance of the best that we see now. Can anyone deny this? Can anyore point to produce of the same marvellous quality as that of the famous old warrior? And if not, is it not a proof that my contention that there is much to regret in the present condition of gardening is true?

I can conceive nothing more ridiculous than the spectacle of a man idly indulging in pessimistic reflections, and I may as well disarm any opponent who contemplates evading my arguments by applying some such description to me, by asserting in the most emphatic manner that no such petty motives actuate me. I sound a word of warning because I believe it to be urgently called for. If unjustifiable pessimism is bad, not less so is that easy optimism which declares that all is going well

with the world, and that the right progress is being made in exactly the right way. A few years ago one of our influential dailies published a series of sensational articles on the state of the navy. Did people believe that what that journal said was true? Not at all. They took refuge in that optimism which is at once so cheap and so simple, and pooh-poohed the whole matter. But little by little it leaked out that all these damaging assertions were correct, and that if the moment swiftly came when we should have to fight for our national existence we should have neither ships nor men to do it with. Away with all this mutual back-scratching and childish vanity. Whether in regard to ships or gardens it is dangerous. Let us have a little wholesome truth-speaking. There never was a moment when light was worse wanted than it is to-day.

Our old gardeners were plain men, but they did noble work for Britain. Years ago, when I had not yet got out of my teens, my father was wont to take me to the leading shows, perchance with a view to sowing the first seeds of a sound garden training. It is well within my recollection that at a northern show many years ago, just how many I hardly care to recall, a great gardener near the Scottish border exhibited a bunch of Hamburghs that weighed close upon 20 lbs. No such bunches do we see now. Whether or not the skill that produced them is wanting amongst the gardeners of the rising generation, the fact remains that they are things of the past. I make no apology for thus reverting to the Grape. It is the king of fruits in the estimation of most gardeners. The times are surely not yet past when the condition of the vinery is an index to the gardener's skill. We hear much in these days about express Grape growing, and makers of Vine manures give us startling details of the marvellous results which they (and the manures) have achieved; but claims, however honestly made, are one thing and public exhibitions quite another. Turning to the examples of Grape growing that are to be met with in the great market establishments, I ask if any cultivator will give the same credit to them as to the splendid examples to which I have referred. You may grow Grapes by the acre, just as you may turn out sausages by the million, but in neither case is there the skill required that is needed to produce the very finest examples. It is as easy to grow a square acre of Grapes of a medium quality as it is to grow a square rod, provided the glass and other requirements are there; but neither glass nor money, be they ever so abundant, can turn out the noble bunches that we used to see.

I am venturing into dangerous quarters when I step into the Rose garden. Our rosarians may not be as great as their predecessors were in cultivation, but as writers they are far more formidable. Perhaps we got the better Roses in the old days from this very fact. Rose growers who display a consuming anxiety to trip each other up on controversial points have the less time to spare for their gardens. All accounts agree that the latest show of the National Society in London was the best ever held. But on what grounds? With scarcely an exception it was quantity that had impressed the critics. It is a sign of the times. Ever bulk and numbers instead of high excellence. No one wishes to say that the show was a bad one. It was a good show, and one that gave those who saw it pleasure; but if anyone wishes to claim that it was the equal of some shows which have preceded it, then in the light that shines reflected in my memory from the days of Baker, Jowett, and Grant I raise the flag of opposition. I do not think that the quality of Roses as grown by amateurs is better than it used to be years ago; I do not think it is so good. In spite of all the books that have been written of recent years there is, to my mind, a decline, and I attribute it to the absence of that thoroughness which distinguished the older generation of growers.

But perhaps the most marked deterioration is noticeable when we look into general outdoor fruit culture. The market man may be improving his methods under the effects of a great deal of outside pressure, but the gardener is assuredly not doing so. I see proofs of this almost every day; indeed, garden visiting, which used to be one of the greatest sources of enjoyment to every gardener, is shorn of much of its pleasure because of this falling off in the standard of outdoor fruit growing. From what unfortunate cause does it arise? Is it because indoor work alone is thought worthy of attention? It is the exception, and not the rule, to meet with perfectly trained trees. Gardeners either cannot or will not give the attention to this department that they used to do, and unless a determined effort is made to improve matters the time will speedily come when the condition of our garden fruits will be as disastrous as the state of the navy was a few years ago.

Specimen plants, we are told, have had their day. I am sorry for it. They may have been open to criticism as garden ornaments, but they were conducive to those habits of skill, patience, and continued interest that are so praiseworthy. I doubt if modern gardeners ever get to feel the affection for the small here-to-day-and-gone-to-morrow style of material which they had for their fine specimens. And if affection goes it will be a bad day for gardening.

Much more remains to be said on the decadence of gardening, but for the present I leave the subject.—A TRAVELLER.

[Our correspondent may "leave the subject," as he says, "for the present," but we shall be a little surprised if his views are accepted as beyond the pale of controversion by others not less capable of judging than himself. All the same he is entitled to express them since he has not sought to do so in an unpleasant way. He has no doubt seen a great deal in his "rounds," and it is rather to be hoped that his last one would take him to Shrewsbury.]

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE members held their monthly meeting on Wednesday, the 11th inst., in the Society's rooms. Mr. John G. Newsham was elected to the chair. Mr. C. Scott then read the third and final paper on Chrysanthemum culture.

The essayist commenced his concluding section of the subject by giving instructions for taking the bud for general and exhibition purposes, referring to those varieties that in this district are either too early or too late for the exhibition held in November. Watering, stimulating with liquid manure, protecting, and every matter necessary for the perfect development of the flowers, were successively dwelt upon, until, after instructions about dressing the blooms, they were finally deposited on the show boards for exhibition and competition. Like the previous sections of the essay, the final one was full of good practical advice and instruction, and gave very great satisfaction. Mr. C. Scott has been an exhibitor at the Society's annual show for eight years, and during that period has gained over 100 prizes, about seventy of them being firsts.

The exhibits for the evening were Tomatoes and Pompon Dahlias for professional and amateur members respectively. Messrs. W. Artindale and Son of the Sharrow Vale and Nether Green Nurseries exhibited a fine collection of Carnations, Picotees, and double and single Begonias; also a number of well grown herbaceous blooms. They were awarded the Society's certificate of merit, which they well deserved.

Numerous references were made by the members present to the death of Mr. W. K. Woodcock of the Victoria Nursery, Humberstone, who was one of the founders of this Society, and for many years Honorary Secretary until his removal from Sheffield. After that period he frequently officiated as judge at the shows, and always took great interest in the welfare of the Society for which he worked so hard during its early years. He was very highly spoken of, and his death greatly regretted. After the admission of new members a vote of thanks to the essayist and one to the Chairman were passed.

POTTING ROMAN HYACINTHS.

EARLY bulbs of Roman Hyacinths may now be placed in 4½ or 5-inch pots. Good firm bulbs should be selected, and as many arranged in the pots as each will conveniently hold. Prepare pots, crocks, and the compost before commencing. The ingredients forming the compost may consist of loam two parts, leaf soil one part, decomposed manure half a part, crushed charcoal and silver sand quarter part. Mix the whole thoroughly, and use moist.

The pots and crocks must be clean and dry. One large crock over the centre hole and a few smaller scattered over will be ample, making secure against soil washing in by a layer of moss or rough fibres from the compost. Fill in the compost about half the depth of the pot, gently shaking it down. On this place the bulbs closely together, four or five usually being the number which can be accommodated. Do not press them down hard, but fill in the compost over them, merely allowing the tips of the bulbs to be visible. When the potting is concluded stand the pots together on a surface impervious to worms. Coal ashes form a good base. Give the soil a good watering with a fine-rosed can.

After the pots have drained cover them over to the depth of 6 inches with leaf soil passed through a riddle, or with cocoa-nut fibre refuse. No further attention will be required until growth appears and advances an inch, when the pots must be removed from the plunging material. Place in a frame and shade from direct light, gradually inuring to the full light as the chlorophyll, or green colouring matter, becomes developed in the growth.

A cool very light position near the glass in a frame suits them admirably until the time when it is necessary to introduce them to a little heat and moisture for forcing into flower. After being taken out of the plunging material and exposed daily to light and air, watering must be duly attended to. The drying of the surface soil will indicate when water should be afforded. Admit air daily in favourable weather; this will keep the plants sturdy, and prevent any lengthening of the foliage. The roots, however, having well developed during the time the pots were covered in the plunging material, now increase rapidly. This is a great advantage in order for the flowers to develop early and freely when the plants are given the stimulus of increased temperature and a moist atmosphere to bring them into bloom.

Bulbs potted in August or early September may be had in flower in November, but when required for any given date it is best to allow plenty of time. Use firm sound bulbs, whether they are the largest or only of medium size.

The season for having Roman Hyacinths in flower may be extended by potting at intervals until October. September pottings will give plenty of time to have the plants in bloom at Christmas, or even earlier, and they may be retarded later. A temperature of 50° to 55° for about three weeks will bring them well into flower.—S.

WORDSLEY AND KINVER.

JULY was drawing to a close when the decision was arrived at to pay a visit to Wordsley and Kinver, in the fertile county of Worcester. Rapidly as the train sped on its way, one could see with pleasure the crops in the celebrated Vale of Evesham. Not that these are as heavy as they have been in the years immediately preceding —late frosts having told their tale in the lightness of the fruit here, as in many places over all the country. However, this may not be altogether unfavourable to the growers, as prices must be higher for the best produce, and it will allow the trees to recuperate after the tax that has been put upon their energies by the immense crops of the past few seasons. But it was not to enter into the aspects of fruit in Worcestershire that the journey was made, but to see the establishment of Messrs. E. Webb & Sons, at Wordsley, with the firm's seed farms at Kinver.

Alighting from the train at Stourbridge Junction a trap was found in waiting, and the drive through Stourbridge entered upon. The town is rather an old one, with narrow streets, but these being left behind a broad, hilly country road stretched in front with the houses of Wordsley showing in the distance. It is not a long drive, but a very pleasant one, and before the end of it the immense warehouses of our destination could be seen towering high above the surrounding buildings. The headquarters of the firm are not on the main road, but in an out of the way corner off one of the smaller streets of the village or town. It is only their size that makes them conspicuous from afar, and extensive though they appear from a distance they seem to enlarge materially when the place is actually reached.

WORDSLEY.

It is fitting that a few words should now be said about the business that has grown so rapidly under the proprietorship of the two brothers, by whom it was launched thirty-five years ago. Not that the Webbs of Wordsley were unknown prior to 1862. But the late Mr. Edward Webb was a mill owner, a glass manufacturer, besides other things, and not a seed grower, this section of the firm being started by his sons, Mr. William and Mr. Edward Webb, who control it still. From the elder brother many interesting particulars were learned, and a conversation with him goes far to explain the growth of the business, for it cannot be doubted that his straightforwardness, geniality, and clearsightedness have tended greatly in that direction. Both he and his brother, who was away at the time of the visit, give their personal supervision to the concern, which comprises so many different departments, each with its responsible manager, who reports direct to the principals themselves.

The divisions of the firm are really six in number, of which the oldest is the mill. Then there are the Hops, the wool, the manure manufactory, the farm seed, and lastly the garden seed, the latter being the juvenile section of the firm, having had its inception about twenty-two years ago. Considering the innumerable details connected with all these, it cannot be wondered at that the brothers decided to relinquish the glass works some time back, and devote their energies to the remainder, and for most men this would be more than sufficient. As Hop dealers Messrs. Webb are well known in the Borough Market, while their wool trade is not very much smaller. With these we have nothing to do, but a peep into the warehouses devoted to these products showed thousands of pockets of the one, and equally large numbers of bales of the other ready for placing on the market at the proper time. These two departments alone must entail a vast amount of hard work in buying and selling to the best advantage. The mill was not visited, as the time at disposal would not permit of it.

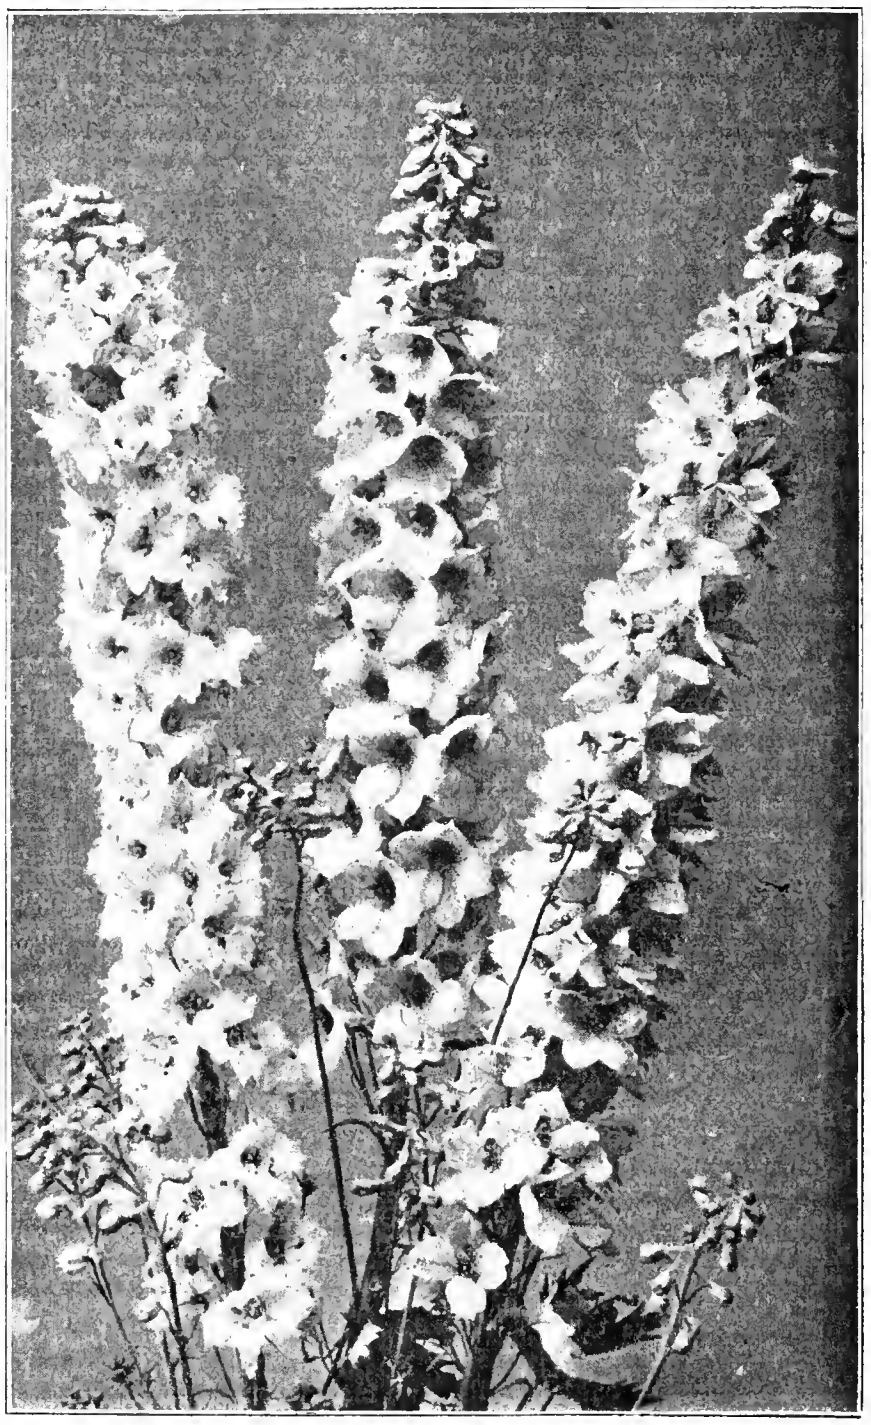

FIG. 24.—WEBBS' DELPHINIUM.

Regarding the manure works, which are situated at Saltney in Cheshire, it need not be said that they also could not be seen, but their extent is comparatively well known. It will be remembered that some years ago Messrs. Webb bought out Messrs. Proctor & Rylands, who originated the Saltney works. To these the business that had been established in manures at Wordsley was transferred, making one vast concern whence thousands of tons of artificial manures are distributed yearly throughout the length and breadth of the land. The mixtnres are mainly for agricultural purposes, though excellent compounds are made up for the garden. One point in connection with the manure works is the system of testing all the mixtures that are sold on the farms at Kinver. Not only those for the garden, but for the farm also are carefully tried with a view to ascertaining their value, and as minute records are kept of each trial practical results are readily arrived at. In addition to this, experiments are yearly made with fresh compounds so as to make all possible improvements on existing mixtures. We saw the varying effects of some of them when driving through the farms at Kinver, but details cannot be given here.

In the farm seed warehouses it was astonishing to see the immense quantities of Mangold Wurtzel and Swede seeds there were in stock, and which must have mounted to several thousands of bushels. While these formed the major portion of the bulk of seeds then in store, there were, of course, considerable amounts of all other seeds that come under the farm section. Trials of all of these are made at Kinver in order to insure the germinating power of the seeds, as well as to be certain that they are true to name. The arrangements for the fulfilling of orders here and in the garden seed department are admirable. Every facility is at hand to favour rapid work, and the employés, no doubt, take the fullest advantage thereof. The amount of floor space in the several warehouses, we were informed, exceeded 3 acres, and as most of it was occupied a slight idea may be formed of the quantities of stock on hand. This, of course, is inclusive of the Hop and wool stores. Throughout the warehouses fire-proof doors have recently been fitted.

There is a new department just being commenced at Wordsley which will become an important one in the course of a few years. For some time the firm has recognised the importance of growing its own stocks of seeds of the choice florists' flowers, but the absence of glass houses has been the effectual obstacle to its being done. This is now partially removed, for the erection of houses has commenced, three long span-roofed structures being completed ready for occupation. As they are light, well built, with ample accommodation for ventilating and heating on sound principles they will doubtless answer the purpose intended and give satisfactory results. More houses will be put up as they are required, and the department will eventually become an important as well as an interesting feature of this thriving business.

Another word or two about Wordsley, and Kinver must be noted. The block of buildings to which momentary attention is now to be given comprise the private rooms of the principals, of the cashier, and the chief clerk, with the general offices, and a reading-room for the employés. Thirty-five years ago a small portion of this sufficed for the whole of the seed business, and at the present moment the whole of it scarcely contains sufficient space for the clerical work that has to be done. Looking from this to the warehouses, and thinking of the business that is done, one is surprised at the ability and the indomitable perseverance of the two men who have built up the whole piece by piece, and are even now contemplating the erection of another warehouse, though the last one was only completed in 1895.

Kinver.

The farms where all the trials are conducted of manures, farm, and garden seeds are situated at Kinver, where about 1400 acres are under cultivation. This is some four miles from the central establishment to which we have referred in the preceding paragraphs. Driving towards the farm we pass the private residence of Mr. W. Webb, where the houses are splendidly stocked with plants, Begonias especially making a superb show when we had our peep in. The estate is a charming one, about a mile from the offices, and it is well maintained, the front of the residence looking over beautiful lawns, dotted with trees, to the main road. But we could not tarry here, or time would not have permitted the drive round and through the farm, a tour that was anticipated with a considerable amount of pleasure, as it was under the guidance of Mr. Harding, the head of the garden seed department, and the manager of all the trials. It was from him we learned that about 1000 acres of the Kinver farms were the freehold property of Messrs. Webb, the remainder being held by lease.

The progress made was not very rapid, owing to two things. First, the hilly nature of the road; and second, the frequency with which we stopped, now to see a splendid field of Barley, then one of Oats, of Mangold Wurtzel, of Swedes, or some other crop of more than ordinary excellence. Wheat was not seen in such large quantities, but here and there a fine field might be observed. But no matter what the crop or where it was situated, whether close to the farmstead or distant from it, the whole of the land was wonderfully clean—in decided contrast to much that was not in the occupation of the firm. Thorough working of the soil, judicious manuring with natural and chemical foods, together with thorough cleanliness, are standing orders at Kinver, and they are more than repaid.

While we propose giving more particular notice to the garden seed products, we cannot refrain from calling attention to a few of the leading things on the farm. Of the Barleys it is almost superfluous to say that Kinver Chevalier was unquestionably the best of the several excellent varieties grown, while of Oats the pride of position must be divided between New Winter Black and Newmarket White, both of which were superb. Pre-eminent amongst the Wheats stood a new one, known as Webbs' Standard, which is to come out this season for the first time. It is of splendid habit, with long ears of beautifnl grain. Like the firm's Challenge White this will in all probability take a very high place in the estimation of growers. Amongst Swedes Webbs' Imperial was looking far the best, while of Mangold Wurtzels there was little or nothing to choose between Golden King and Champion Yellow. Other crops, equally meritorious, cannot now be specifically mentioned.

Proceeding on our journey, we pass fields wholly devoted to trials of one or another kind of crop until we reach the garden seed department, where the rows of Peas, Beans, Cabbages, and the scores of beds of beautiful flowers excited a renewed interest. It was here, after driving for some two hours, that we left our trap for a time, so that all the plants in growth could be carefully examined. There had been no effort made to please the eye in the arrangement, as visitors are few. All the planning had been done with a view to insure ease in comparing one variety with another, and to be certain that all were growing under identical conditions. Notwithstanding the fact that effect had not been sought, the display as a whole was very charming, and would make a lovely picture for an artist whose hand and eye had the cunning to transfer the varying colours and forms to his canvas. Such would not be an easy task by any means, though many knights of the brush might think it a very simple thing to do.

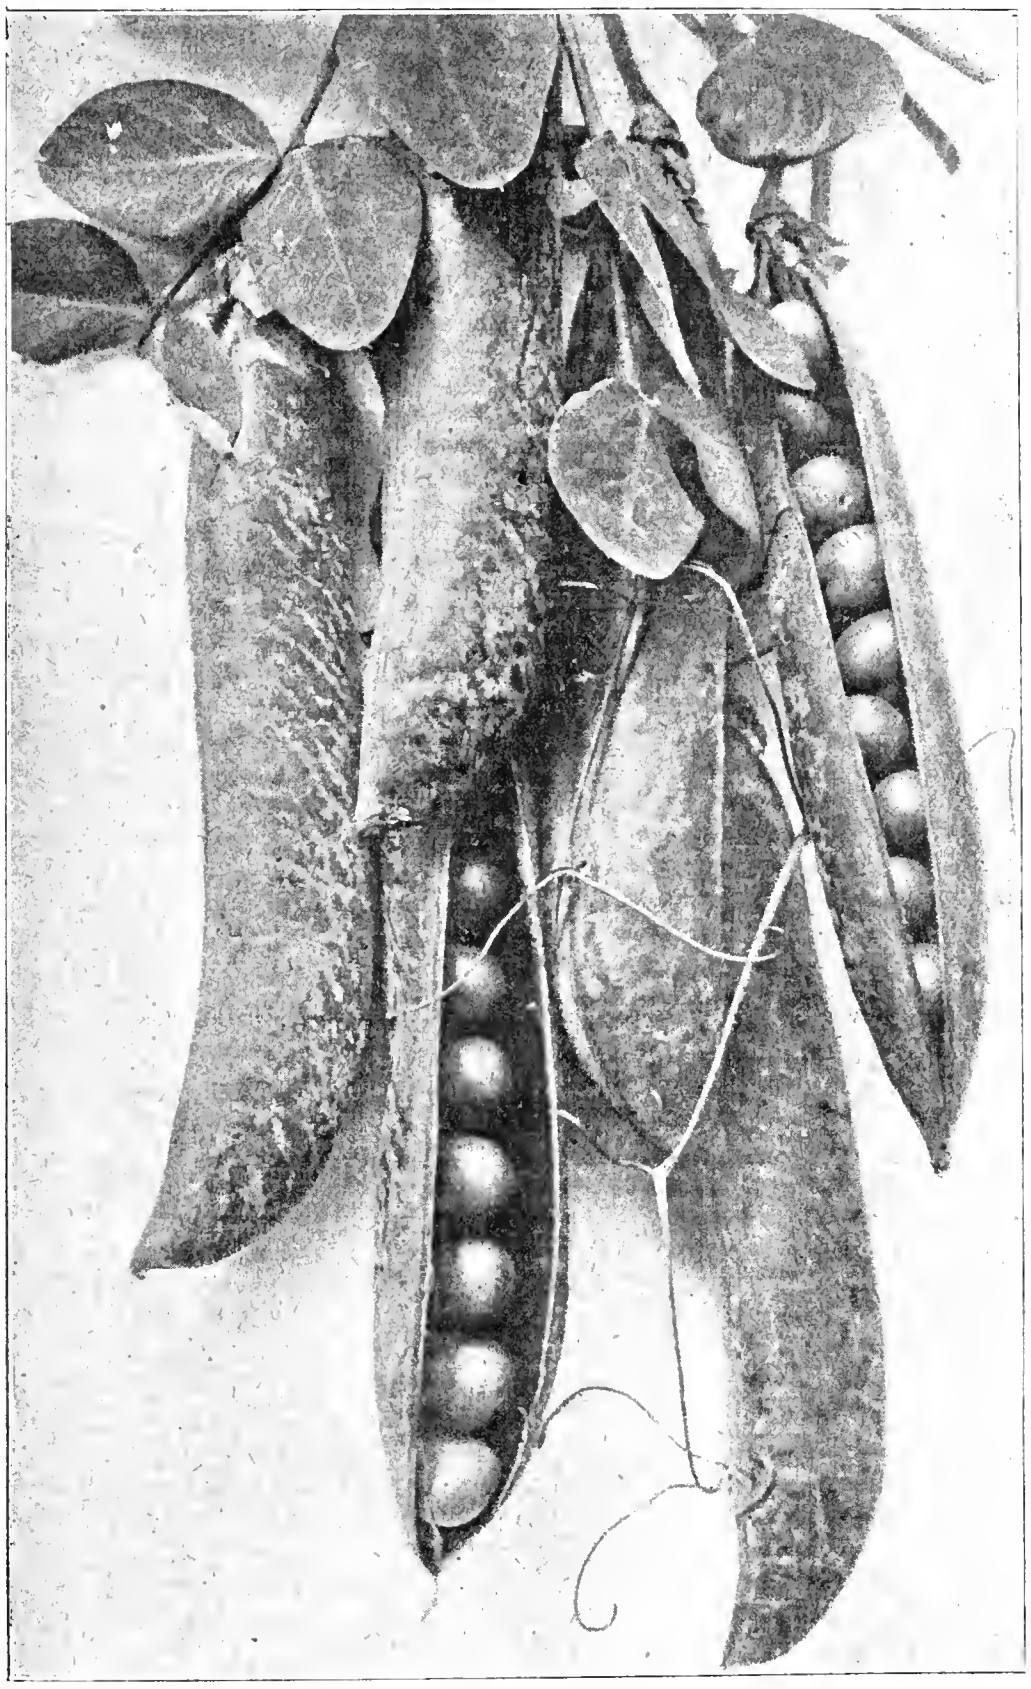

Fig. 25.—Pea Stourbridge Marrow.

The trials of Peas comprised several scores of varieties, good, bad, and indifferent, and of most of them there were two rows, sometimes more, and very occasionally only one. All had been given precisely similar treatment, and they had been carefully looked after, but no water had been given either to these or any other crops, for the simple reason that there was none to give. Of all the varieties the most conspicuous was Senator, which was carrying prodigious crops. Stourbridge Marrow (fig. 25) was also splendid, as also were Talisman, an exhibition variety, and several of the well-known older sorts. Broad Beans were over, but they had been grown in similar manner, the same system having been adopted with the French and Runner varieties, pride of place being taken by Hundredfold in the former and Eclipse in the latter. The collection of Lettuces was exceedingly interesting, most of the more popular varieties, with a few new ones, being represented. Very noticeable were Magnet and Criterion in the Cabbage section, with New Exhibition and Wordsley Gem of the Cos.

That grand Cabbage, Webb's Emperor, needs no word of praise here, as it is an established favourite with the majority of cultivators, as well on account of its handsome appearance as its excellent flavour and colour. As an early Cabbage First of All must occupy a prominent position in the long list of sorts now grown. Matchless Sprouts promised well, as did many of the firm's specialities in Cauliflowers, Broccolis, and Borecoles. The handsomest Beet was undoubtedly Reliance, a short crimson-topped variety of perfect form. Defiance Intermediate occupied the post of honour in the Carrot beds, though Market Favourite was, of its type, equally meritorious. Little Wonder Savoy looked as though it will render a good account of itself later, as did Kinver Globe. Very fine is Emerald Gem Endive, and the same may be said of Prizetaker Turnip, which is a white of great beauty. Of Onions it was too early to form a decided opinion, and as many other kinds of vegetables were in a similar state we will leave them and turn to the flowers.

The many beds of hardy annuals were making a lovely display, the plants appearing to be absolutely clothed with flowers. The dwarf Naturtiums were a blaze of scarlet and yellow, while the crimson hue of Linum grandiflorum rubrum looked glorious with the sun shining upon it. The superb Stocks, Zinnias, of all colours, the Cape Marigolds, Collinsias, Clarkias, Godetias, Bartonia aurea, and dozens of others,

each had its bed, and all were doing their best to insure a glorious display. The Asters will he most interesting when in flower, as the trial is of many of the well-known varieties from German and English seeds. Two Poppies arrested tbe eye as it roamed over the beds, one a pure white and the other a rose. The former was named White Swan and the latter Rosette, and they are amongst the finest with which we have met.

The fragrance around us told we were in proximity to the beds of Mignonette, of which there are several. The two best varieties are Golden Gem and Webb's Dwarf, the latter only 9 inches in height and the former 12. It is wonderful how proliferous these are, producing numbers of their perfectly clothed spikes on every plant, and making hoth of them splendid for bedding purposes. Then we noticed some plants of Carnations carrying an extraordinary numher of flowers, and we found that it was the firm's strain of mixed for bedding. Its excellence cannot he douhted, though, of course, some of the hlooms were not quite perfect. Calliopsis Sunheam and Golden King were gracefully beautiful, while several beds of annual Chrysanthemums were almost equally attractive. Delphiniums are a speciality, and in fig. 24 we give a photographic reproduction of three spikes that were cut at the farm in the flowering season. There were many others whose several merits entitle them to inclusion in these notes; but they, with the greenhouse florists' flowers, must wait until the next visit to Wordsley and Kinver is paid.

Enormous as are the quantities of all kinds of seeds grown here, it must not he supposed that it provides all the supply that is required. Such is by no means the case, for the firm has growing in various parts of the country Barley, Oats, Wheat, Potatoes, Swedes, Mangold Wurtzel, Peas, and other crops, covering an area of something between 15 and 20,000 acres. Glancing through the contract book, it could he seen that this enormous total was made up in lots of from 10 to 50 acres, and that Lincolnshire, Hereford, Worcester, Kent, Shropshire, Essex, and other counties each had a share. We can say no more of this our first visit to the Worcestershire home of the Webbs. We had a busy, an interesting, and instructive day, and tender to Mr. Wm. Webh our best thanks for his cordial reception, and his readiness to give all the information that was asked for.—STRANGER.

ABOUT SUBSOILS.

SUBSOIL may he described as the layer of earth immediately below the ameliorated portion, the former not heing usually interfered with in preparing tbe ground for crops with the plough or the spade. In spade husbandry the suhsoil may be about 12 inches from tbe surface downwards, whilst in ordinary farm operations the surface is not stirred deeper than 6 inches. There is, therefore, a great difference in soils as they are operated on in gardening and farming; and there is a difference in subsoils, though some vary little in composition from the surface soil, yet there is generally a great distinction between them in cultural value.

The surface or worked soil contains a very much larger proportion of organic matter and soluhle food for plants, and though liable to impoverishment by the crops, is henefited by the roots and other parts of such plants as remain after the crop is taken. These decay, and in combination with applied manures give the surface soil an immense advantage over the suhsoil, as it can derive little or no increase of organic matter through the comparative inaccessibility of air and rain. It must not, however, be overlooked that the surface soil is altered in texture by tbe crops. It is made more open by the roots that traverse it, and its friableness is increased by the operation of tillage. This admits of the freer access of the great solvents, air and rain, insuring a more speedy decomposition of organic matter, or the formation of it, this decomposition causing some of the soluhle matter to pass down to the subsoil, which, it is unnecessary to say, is a direct increase to the resources of the soil as it affects the crops. The compounds taken down remain in the subsoil in proportion to its retentive power. They exert influence, useful as food, or for food manufacture out of otherwise inert matter, or are injurious to plants from the lack of the necessary correctives essential to changing the compounds into plant food. Some soils may be almost sterile before they are exposed to air, or they may be of little value for useful crops until the deleterious suhstances in the subsoil have been changed by the application of some materials, as that of lime to peat or boggy soils, which are impregnated with the salts or oxides of iron.

If the subsoil he sand or gravel, or otherwise of a loose nature, the soluble compounds brought into it by rain soon pass away, so that there is less addition of useful food, and it follows, less danger of the deleterious matter being retained. If, on the other hand, the suhsoil is clay, it retains what is brought down by rain passing through the surface soil, which may in effect contribute to the soil's fertility, or prove deleterious through retaining the poisonous as well as the soluble compounds that are useful as food for plants. An efficient system of drainage, it is evident, must form the basis of all operations having for their object fitting the soil for a variety of crops, and for making the most of the cultural operations through the changes effected by the free access of air and rain, to assist in the disintegration of stuhborn material, and change the otherwise inert or injurious compounds by the application of corrective material into nutriment for crops.

Suhsoil is apt to be overlooked in deciding on the fertility of soils, yet it exerts a commanding influence on the surface soil. When the subsoil is open and sandy it is poor, through its lacking the means of retention of the soluble compounds brought into it from the surface soil hy rain, which drains away rapidly, and as evaporation from the surface soil is correspondingly free, the plants grown thereon suffer greatly in time of drought. It is evident that to materially improve such soil some substance must be employed that will render it more retentive alike of rain and of the manurial matter employed; the non-calcareous by a dressing of chalk or of clay marl, whichever may be most convenient, though the latter would perhaps be the most effective from its adding by the divisibility of its parts to the rooting area and the increased retention of the solvent compounds. It is well perhaps to notify that a siliceous marl is only valuable to a light soil in proportion to the amount of chalk present, and deleterious in relation to the percentage of silica or sand, on which account it is not nearly so beneficial for light soil as the clay marl having clay or alumina as a component part. To effect a permanent improvement, 100 cartloads per acre, mixed with the soil, but not so as to interfere with its tillage, is a proper quantity.

Some light soils have, beside a sandy or gravelly subsoil, an under stratum of clay, or conglomerated sediment of various earths largely impregnated with oxides of iron, which retains the water to a certain level, and from such Horsetails and Thistles spring strongly and in profusion. Such reservoirs of moisture are of no value, but the contrary, inasmuch as they contain substances poisonous to useful plants through stagnation. The water in such cases must be carried off hy drains, so as to prevent its lodging within 3 feet of the surface; indeed, all soils should be freed of water beyond their retentive power within 3 feet of the surface by an efficient system of drainage.

Where the suhsoil is clay, more or less impervious to water, the rain passing through the surface soil is retained, or otherwise, according to the degree of porosity, and collects in the low places or hollows, stagnation ensuing, forming organic acids in consequence of the absence of air acting on the decomposing remains of previous crops, or the remnants of the manures not appropriated by prior crops. The surface soil in consequence is rendered cold, sodden, and sour. Nothing but an efficient system of drainage can render such land for profitable cultivation, inasmuch as other operations are frustrated until the land is freed of the stagnant water and poisonous compounds. The drainage alone will change the nature of the subsoil, as the water dislodged hy the drains will be followed by air, and the organic elements will form nitric acid in addition to that brought into the soil by rain, whereby the poisonous compounds will be neutralised and nitrogenised, and food stored in the soil for the support of useful crops.

Clay subsoils should be well hroken up. For gardens, whether flower, vegetable, or fruit, the land should be trenched, not turning the top ameliorated soil under one or two spits of stubborn material, but keeping all the workable portion uppermost, the stiff material being kept under, yet disturbed in order to form passages for the free percolation of water through it, and to insure cavities for the storing of air, moisture, and warmth. Although the ameliorated soil should be kept at the top, some of the under layer may he hrought to the surface, as such contains substances required by plants that have passed into the subsoil, leaving the surface more or less exhausted. It is a direct means of affording new soil, which, exposed to the atmosphere, pierced hy frost, or baked by sun, becomes pulverised, mixing readily with the bulk, enhancing its fertility. There is the still further advantage of increased depth for roots, whilst the blending of the manures with the new soil improves the whole considerably, a larger food being provided and furnished with sustenance for crops.

Perhaps the greatest effect next to breaking up a clay soil is to burn some of the stuhhorn material; this alters its texture, rendering it more open, consequently more permeable to air, water, and the roots of plants. Its affinity for ammonia is also increased, and a much greater proportion of soluble alkalies, especially of potash and soda, provided; but that depends in a great measure on the degree of burning, for if hard burned the clay will be of the nature of hricks, and its alkaline constituents are then less soluble than of the clay in its original state. The most that should be sought by burning is that the clay may readily crumble. In that state 100 cartloads per acre is a fair dressing, applying it to the surface, and it will render a good account of the ammonia within reach, ahsorbing it from the atmosphere and from manures or by whatever means supplied.

In the case of very stubborn clays it is advantageous to mix some of the harder burned particles with the stubborn material at the bottom of the trenches, by which means the permeability of the soil to air, rain, and roots is made more durable, acting alike as a storehouse of moisture and food, from which the crops can draw supplies in times of drought, the roots being attracted downwards by the moisture they inadequately receive at the surface, and as they must in due course decay they tend to open the soil to a greater depth, and supply organic matter for its enrichment. In that way soils which have only a thin layer of ameliorated soil can, no matter how stuhborn the subsoil, be deepened, and in the course of a few years so much so that the ground can be trenched two or three spits deep, blending the whole mass with very great benefit to the crops. What most land needs is new soil brought to the surface to be ameliorated and enriched by the action of light, air, and rain, pulverised and made workable by frost or sun, in which state the soil derives the greatest benefit from the solid manures applied, and the whole staple is permanently improved.—A.

ROSES

Stray Notes.

There is something else required, I said, besides intelligent pruning to make Maréchal Niel a true perpetual bloomer as a standard in the open, and that is thorough protection from frost. This means protection in spring as well as winter, in March and April as well as December and January. It breaks very early by nature, but care must be taken of those first breaks, as from them and from the secondary shoots arising from the first shoots come very often the only buds. I will repeat how I protect mine, my garden being so subject to frost that Figs are generally killed to the ground unless protected. Short half-standards are planted in a slanting position, so that the head is not much more than a foot above the ground. In November the whole is pegged down to the ground, then covered with straw or similar material, and above that with earth, just as Mangolds are clamped in the fields. The advantage of this very thorough protection is the being able to regulate the period of the first bloom; you can raise and "start" them just when you like, as a Vine. Mine were only just breaking about the middle of May, nearly two months later than they would have done if left to themselves, and the flowering shoots were therefore quite untouched by frost. It is these shoots as a rule that will produce the successional blooms, but the rule has its exceptions. This year I had three or four shoots a yard long or more, springing from quite old wood, which produced blooms at the extremities, but this is exceptional. In unusual heat, such as we have had lately, the long flowerless shoots will sometimes break in side flowering shoots, and nurserymen often find, in a hot autumn, that the long maiden shoots which they have shortened because they have passed the stakes bear flowers pretty freely. Nevertheless, if left to itself, and to break when it will, the Rose will often be a poor bloomer, and a still worse perpetual.

But I had not any intention of representing Maréchal Niel as "a satisfactory garden Rose," whatever that may be meant to imply. "Garden Rose" has a specific meaning in N.R.S. nomenclature, and does not include Maréchal Niel. And if the term is taken to mean, as I fancy it sometimes is, a Rose that will appear at its best without any care being taken of it, I cannot give any opinion on such a matter, as I have no experience. My Roses are all taken care of, and would not give me so much pleasure if it were not owing to my care that they flourished. No small amount of such care, as well as good culture, must I am sure have been given to those magnificent blooms of Maréchal Niel which Messrs. D. Prior & Son showed on certain occasions this season, and the remembrance of them really makes me too impatient to continue a discussion upon a suggested comparison between this Rose and Medea.

Yes; I am sure—it seems only natural—that I take greater delight in a fine bloom whose beauty has been much enhanced by care and watchfulness. Surely this is the essence of the pleasure of competition at shows. If it is only the richness of your soil, or the excellence of your gardener, where does the personal element—the delight of having won by your own exertions—come in? If it is by your own cultivation, selection, protection and care that you can produce a perfect Souvenir d'Elise in full size and beauty, or a La Boule d'Or, erect, golden, pointed, with stiff long wide wings, which is plainly superior to all others, your toil and care has its full reward.

The mention of the latter Rose reminds me that two or three years ago—I think it must have been when I got the medal for it at Gloucester N.R.S.—my youngest daughter suddenly announced that she had made a riddle (charade). "My first is a fierce cow, my second is what you shut, my whole is a Rose." *Answer:* Bull-door. Forgive her—her years are tender.

"D., *Deal*," still seems to think that some other reason should be given for holding the Northern N.R.S Show at Norwich besides the obvious one that it is, literally and actually, a northern city. The "someone" who made the remark "waggishly" that it must be because both began with "Nor" was the Dean himself, at which I was. I confess, much surprised, because, of course, that *is* the reason. Northwich (Norwich) is the capital of the Northfolk (Norfolk) of the formerly separate kingdom of East Anglia. North, indeed, to East Anglia was the county of the Northfolk, for there is nothing to the north of it but the open sea, and very little to the west, as I fear was found out by travellers to it from the N.W.

It is more difficult to believe that it is actually a Norwich—northern city—as compared with the rest of England; but even this is true. If you lay a ruler across a map of England you will find it north of Wolverhampton and about level with Lichfield, and surely this is northern. I explained all this at a N.R.S. meeting, but am not surprised that people cannot understand it, for, oddly enough, I can hardly realise it myself. It is the railway that bothers one. When you go down the seventy miles to Ipswich by G.E.R. you take it for granted that you are going East, whereas it is really N.E. Down the Thames to Margate would be East, and after Ipswich the remaining forty-five miles to Norwich is due North.

I much regret that it is so inaccessible from the North and West, especially at the missing the Roses of Messrs. A. Dickson & Son, which are always most interesting at the northern exhibition. But there are a good many East Anglian exhibitors, and they have had many a weary journey to the N. and N.W. It is a matter of regret that there are so few amateurs in Norfolk itself, and practically no trade growers; but Colchester itself would confess that the Norfolk and Norwich is much the strongest and most flourishing of all East Anglian horticultural societies. I predicted that the N.R.S. would be thoroughly well received and treated at Norwich, and am heartily glad that it has generally been considered a success.

Among all the hardy annuals submitted to gardeners in the horticultural Press, nothing is more hardy or more annual than the advocacy of own-root Roses. It is a crop that never fails, and generally ripens about this time of year. It is in vain that rosarians repeat what their experience has taught them—that some few of the more vigorous H.P.'s will eventually, in suitable soil, make good plants on their own roots, but that even these are much longer in doing so, and do not flower as freely or give such good blooms as those worked on the Briar. It is no use; it will crop up again next year, I feel sure, and, perhaps, especially if the cutting with a heel is mentioned, be put forward as quite a new discovery, just as I fully expect we have not heard the last of the old saddle graft being a new invention. I do not think that Mr. W. Pea (page 116) meant that his Hero had Souvenir d'Elise, Innocente Pirola, and Madame de Watteville at their best on their own roots, though Dupuy Jamain he possibly might; but rosarians do not believe that "many a good Rose gives of its best and freshest when it has no caterer but its own inherent vigour," though a few may do pretty well.

Among a certain class of horticulturists there is now a strong bias for own roots for everything. There is no smoke without fire, and I think this feeling has been aroused by unnecessary and often careless grafting of certain ornamental plants and shrubs. But, as usual, the reactionary feelings and statements have gone too far. I read in a gardening journal not long ago an editorial on the standard Rose, strongly opposed to all "working," in which it was asserted that budding and grafting were practically the same, and standards were spoken of as grafted plants. I felt a strong desire "to offer some statements" in answer, but wiser counsels prevailed. I have done some such quixotic tilting at windmills before now, with the usual result, and have learnt my lesson.—W. R. Raillem.

P.S.—As the above seems not to have been in time for the last number, I would add a sentence or two. If Mr. Walter Easlea, after taking part for over twenty years in the cultivation of thousands of Maréchal Niel, never expects to get more than a single crop from it, it only emphasises what we all knew before—that no amount of time or experience will exempt us from having something yet to learn. Why "so few specimens are found at the summer exhibitions" is probably because few think it worth while to treat their plants as mentioned above.

Though "D., *Deal*," is chivalrous enough to come to my aid against the windmills, I cannot agree with him altogether on one point. He looks upon the pendent position of the flower out of doors as a defect, and says you see nothing but the outside petals of the flower, which are generally discoloured. True, if the bloom has not been protected; but cut it and turn it up, and it is still beautiful, the outside protecting petals being easily removed. If it had been erect the whole flower would have been spoiled; the fact of its being thoroughly pendent makes it often last longer in bad weather than other equally delicate Roses.

The effect of an abnormally heavy dew on the Tuesday morning before the Norwich Show, immediately followed by a tropical sun, was that all my erect Teas of any shade of red or pink, which were uncovered, were completely spoiled, and all the pendent blooms of any colour escaped.—W. R. R.

New Roses.

We can hardly call Mrs. W. J. Grant, Captain Hayward, Helen Keller, Crimson Rambler, and Mrs. R. G. Sharman Crawford new Roses in the sense that I mean in these notes. They are far too well known and appreciated. But a few of the more recent introductions, and some not yet in commerce, are well deserving of a note. Muriel Grahame does not need much comment, in addition to stating that it won the N.R.S. card of commendation in 1895, the N.R.S. gold medal in 1896, and the first year after introduction secured two of the silver medals as the best Tea or Noisette among amateurs' classes at the National Rose Society's meetings; once at the Crystal Palace, and again at Norwich. In every sense but colour Muriel Grahame is the same with me as Catherine Mermet and its other sport, The Bride.

Laurence Allen is another Rose that deserves special note. I may briefly describe it as a much improved Baroness Rothschild, but with a most delicious perfume. Comtesse de Canay promises well, and is a dark crimson with carmine shadings. The best new Hybrid Perpetual of last year is Tom Wood, a grandly built up cherry red, of great sub-

stance, and a Rose that will be certain to grow in favour when better known. It is a free grower and bloomer, lasting fresh a long time on the plant and when cut. In Ellen Drew we have a beautiful rosy cerise form of Duchesse de Morny. One of the greatest improvements in Roses is Mrs. Pierpont Morgan, a deeper coloured, larger, and better habited form of Madame Cusin. Ceres gives a new shade in climbing Roses, a very creamy white with a yellow and blush centre.

Antoine Rivoire is a valuable addition to the Hybrid Teas; so, too, are Souvenir de Madame Eugène Verdier, Alice Furon, and Charlotte Gillemot. Countess of Caledon is one of our best carmine rose shaded blooms, large, free, and a thoroughly perpetual bloomer, a grand new H. Tea. Rev. Alan Cheales is novel in colour, a pure lake with silvery reflex to the petals, very taking and a good grower. But the most uniquely coloured Rose I have seen this season is Messrs. W. Paul and Son's Empress Alexandra of Russia. On more than one occasion at the Drill Hall, but especially at the last Temple Show, this was in grand form. I cannot describe it better than as a rich lake red, orange, apricot, and a fiery crimson mingled together throughout the whole flower. Certainly one of the most charming Tea Roses we have, and not approached by any other variety as regards colour.

We have seen how very useful Kaiserin Augusta Victoria is, and now we have a climbing variety, which, if true to its parent in form and floriferousness, will become a prime favourite at once. Mrs. Harkness and Paul's Early Blush are synonymous; they are really fixed sports from Heinrich Schultheis, but I am sorry to say Merrie England, another sport from H. Schultheis, is not fixed. It is very attractive, and if constant would become our most popular striped Rose on account of its sweet scent, clear colouring, and freedom in growth and bloom. Plants, which I am positive were worked from the same shoot, have produced the Mrs. Harkness shade, and also the deep rosy crimson so prettily striped and flaked in Merrie England. Self-coloured flowers however good are apt to cause disappointment where one expected a striped bloom.

A few words upon the Roses not yet in commerce and I must close these rambling notes. Lady Clanmorris is a good Hybrid Tea, of Ernest Metz form and colour. Eileen, Bessie Brown, and First Cross are also H. Teas of great promise. The last named is supposed to be touched with other blood, but is a seedling from Mrs. W. J. Grant, fertilised with pollen from another bloom of the same variety. Killarney is one of the most promising H. Teas we have. It is grand in form and size, a soft salmony peach shade, with silvery edges. Of course it is difficult to give a decided opinion, or even description of a Rose only seen upon two occasions, but I am certain Killarney will please all who purchase it next spring. Mrs. Grahame promises well, and is a Tea that reminds me of Kaiserin Augusta Victoria and Madame Bravy combined. I have seen Mrs. Mawley in better form than at the Crystal Palace this year, and I am assured it will be much liked. It has the merits of free growth and flower, two grand points in its favour, while it is unique if rather dull in colour, and of good form.

These are all to come from Newtownards, where the only gold medal new Rose of the season was raised. This is a H.P. named Ulster, a charmingly deep salmon and pink shaded flower of immense substance and size. Other promising new Roses were Mrs. Frank Cant, a paler form of Madame G. Luizet, but quite distinct. B. R. Cater is a H.P. of the Helen Keller shade and form, but more cupped, and distinct in growth. It will, indeed, have to be good if it can in any way rival H. Keller. F. W. Sandford is a charming pale blush; and Royal Scarlet will probably make a grand bedding and decorative variety from the section of single flowers.—A. PIPER.

TOMATO NOTES.

RIPE TOMATOES.

"E. D. S." (pp. 149, 150) advises "picking half-coloured Tomatoes as they become ready, finishing the ripening on a warm sunny shelf, where they colour as rapidly as on the plant, without any deterioration in flavour."

Oh, "E. D. S.!" have you really compared such, for flavour, with fruits gathered absolutely ripe from the plant, and eaten quite fresh? If you have I have no more to say, for I do not want to be involved in any more comparisons. I simply give it as my opinion that fruits ripened on a shelf have not anything like the flavour of those thoroughly ripened on the plant, and eaten very soon after being gathered.

You cannot buy them. No grower for sale is so foolish as to let his fruits of any sort thoroughly ripen on the plant, with the result that they will neither travel nor keep, while the public will cheerfully buy Strawberries, for instance, that do not even *look* ripe.

Let the private grower test really quite ripe Tomatoes from his own plants, freshly gathered, and I am afraid he will hardly be able to appreciate those ripened on a shelf, however warm and sunny, afterwards.—W. R. RAILLEM.

TOMATO ROOTS.

DOUBTLESS, like many other readers of "our Journal," I was much interested in the above article by "E. D. S." in this week's Journal. Will he kindly say what are the proper means of "inducing a constant multiplication of healthy rootlets" in the early and other stages of growth?—S. S.

SOWING PARSLEY.

FRESH, good, and healthy Parsley is a standard everyday necessity in the majority of households. Should this crop from any reason fail, and a long blank occur in the supply, the importance of a constant supply is at once seen. Resolutions are then made by cultivators to avert the inconvenience in future by more frequent sowings made in several positions, where it is thought likely Parsley may succeed.

Spring sowings of Parsley are not calculated to give the unbroken supply demanded, because it begins early the following season to run to seed. The tufts of green, healthy leaves so suitable for culinary purposes then rapidly lose their colour and substance, which are transferred to the flower stem, and employed for perfecting the seed.

Instead of making frequent sowings at various periods of the year I adopt the plan of sowing in August. The plants from this sowing attain to a size sufficiently strong for them to pass the winter without succumbing to damp, which is a great enemy to Parsley in some climates in winter. It is possible in a dry, hot soil, and having to experience a long period of drought in summer, that a majority of plants from even this sowing may run to seed, and lessen the chances of securing good pickings.

Here it will be seen that a spring sowing may come in useful by providing a supply during the autumn and winter. Under ordinary circumstances, however, the previous August sowing should remain in good condition the whole of the year succeeding, or until the next sowing is fit for use.

The sowing made now may be regarded as constituting the main crop. The position assigned for it ought to be an open one, the soil not too rich, but well drained and fertile. Dig deeply, and well break up the particles, leaving the surface smooth and level according to the inclination of the ground. Dry, parching weather will render watering necessary, giving a good soaking with a rosed water can before sowing the seed. Broadcast sowing is the best. Do not sow too thickly. Carry out the sowing while the surface of the soil is moist from the watering. Immediately cover the seed with a thin coating of finely sifted soil obtained from under the potting bench, or any place where tolerably dry. A little shade in hot sunshine will prevent rapid evaporation, and insure a steady, even germination of the seed. Following this little attention will be needed beyond an occasional watering, thinning out any rank patches, and keeping the bed clear of weeds.

Some cultivators find it necessary to protect in winter, but this must be distinguished from closely confining the plants by surrounding with a frame, and keeping on the lights. The protection may be more of a simple character. A few lights supported on bricks serve to maintain the plants dry, while a free supply of air is always circulating about them. Parsley is hardy enough when it has attained a fair size, but liable to damp when small in winter, more especially near large towns.

Nearly all seedsmen possess good strains of Parsley, and such selected stock ought only to be employed, as it is quite as easy to cultivate good stock as inferior. Sutton's Selected Garnishing and Giant Curled have proved excellent in every way with me, and beds of them are not only useful but ornamental.—E. D. S.

GROWING CAMELLIAS.

HAVING referred (page 150) to a healthy plant, and noted how it may be made to fail or to flourish, it cannot but be useful to commence with an unhealthy plant and suggest how it may be improved. The stems have a black, wiry, hide-bound appearance; the leaves are greenish-yellow; the flowers few, because the majority of what buds there were fell off like nuts in the autumn. Let us turn such a plant out of the pot and examine the roots. What do we find? An inert mass of soil, possibly black sour peat, and something like a root or two trying to escape through the drainage, yet arrested by worms. This is no imaginative case. There are thousands of plants in that state—dying by degrees for the want of a fair chance to grow. They cannot get out of the pots and shake off the soil that is killing them; therefore we must help them. This must be done carefully. Every fresh root must be preserved. If the case is a bad one, there being a few white roots, but the majority black and dead, not only should all the soil be picked or shaken out, but the roots should be washed, as if washing a mop. Cut off the dead portions—indeed, cut until life is found; then, while still wet, dust the roots heavily with silver sand and repot in as small a pot as possible. Drain it well, and protect the drainage from the soil with clean turf fibre, which dust with soot. For a plant of the kind under notice this is the compost: Half rather light but decidedly turfy loam containing no lime, the remaining half very fibrous Heath or Azalea peat—not bog—and leaf soil from leaves that have not fermented; mark the condition. To this add crushed charcoal and silver sand liberally, say together, so as to form an eighth part of the bulk. Mix the whole thoroughly. If this compost will not incite the production of roots nothing will.

When should this be done? is the next question. It is best done in early spring, just as the plants are commencing growth, or trying to do so, by those who have a stove or other structure where the temperature ranges from 55° to 85°, and where syringing can be done freely and a moist atmosphere maintained. Those who have not such convenience, but possess a vinery in which the Vines start in a natural manner, may repot their Camellias when the Vine leaves fairly cover the roof, as the temperature suitable for Vines at that stage and onwards will be also

suitable for the plants under notice. If the pots can be placed on a bed of leaves or other moist base it will be decidedly advantageous to the plants. With only a greenhouse at disposal the repotting should be deferred until the night temperature is 60° or thereabouts, and the plants ought to be grouped where they can be kept as close as possible, also shaded. This, with light syringings, will lessen the necessity for frequently watering the soil, and healthy root action will be the sooner induced.

A good guide for repotting unhealthy Camellias when there was not the requisite convenience for dealing with them before, is when the young growths cease to extend, and just as the last-formed leaves are attaining their full size; but the longer the potting is deferred the greater must be the care in preserving the healthy roots and preventing them drying; and the more radical is the treatment, such as pruning off decayed parts and washing the roots, the greater is the necessity for heat, shade, and moisture for effecting the recovery of the plants.

Many Camellias, while not being so healthy as they should be, do not need to have the whole of the soil removed. The soil itself (and the condition of the roots) will suggest to what extent it should be picked out. When the plants are sufficiently healthy to form flower heads they may be repotted when these buds are about the size of Radish seeds, as if they are allowed to grow much larger before the roots are disturbed, as they must be to some extent in repotting, there is danger of their dropping, this mishap resulting in nine cases out of ten from defective root action, the tenth being immature wood and excessively luxuriant growth.

The practice of cutting down Camellias may be briefly alluded to. Any moderately healthy examples, but tall and loose, with naked branches, awkward and ungainly, may be cut down to any extent provided they can be placed in a warm, steaming atmosphere, where they will shortly bristle with young growths, and in a short time form handsome bushy specimens. Numbers of Camellias could be named as not worth 5s. each a few years ago that were subsequently cut down, treated well, and which could not now be purchased for as many pounds.

As to varieties. Camellias should be chosen on the principle of special adaptation to circumstances. Some may require small plants for small greenhouses, others free growers for large specimens, and others, again, sorts for covering the back walls of vineries and Peach houses, which can be furnished more attractively and profitably with these plants than any others.—J. H.

HORTICULTURAL SHOWS.

WESTON-SUPER-MARE.—August 10th.

This, the twentieth annual exhibition of the Society, proved to be one of the best all-round displays yet seen at Weston-super-Mare. It was held, as usual, in the Grove, and a better site for a flower show could not well be found. Everything passed off satisfactorily, and the courteous, hardworking Secretaries—Messrs. Thomas and Cox—together with a zealous influential Committee, are to be congratulated upon the result of their labours.

Liberal prizes were offered for twelve fine-foliaged and flowering plants, which attracted four competitors, a most imposing display being made. Mr. J. Cypher, Cheltenham, was first, having grand specimens. Mr. W. Rowland, gardener to W. Brock, Esq., Exeter, was a creditable second. The third prize went to Mr. W. Finch, Coventry, who had several good specimens, as well as some that were a long way past their best. Mr. G. Hallett, Bath, took the other prize. The competition with six flowering plants was equally good. Mr. Cypher led, Mr. W. Rowland was again a good second, and Mr. W. Finch third, similar positions being held by the two first-named exhibitors in the classes for single specimens. A seedling Dipladenia of an attractive flesh pink colour gained Mr. Rowland the first prize for a new or rare plant in flower, Mr. Cypher being second. Mr. Appleton, Weston-super-Mare, was first for four well-flowered Orchids, and Mr. W. Brooks, Weston-super-Mare, second. Mr. J. Cypher was first for six plants with ornamental foliage, showing grand specimens. Mr. Rowland was second, and Mr. Hallett third.

Ferns were admirably shown by Mr. W. Rowland, who took the first prize for nine specimens, the second prize going to Mr. W. Brooks. Mr. Rowland was first and Mr. Hallett second for Adiantums, while for hardy Ferns Mr. J. P. Capell, Weston-super-Mare, was well first. Fuchsias, Zonal Pelargoniums, Tuberous Begonias, Petunias, Balsams, Gloxinias, and Cockscombs were principally locally grown, and scarcely so good as seen at former shows. Table plants were particularly good, and the competition keen. Mr. G. Cole was first, Mr. J. B. Brain second, and Mr. W. K. Wait third. Two classes for groups arranged for effect were provided. Mr. W. Rowland was easily first for a group to occupy a space not exceeding 100 square feet, and his arrangement and the materials used were very pleasing; Mr G. Hallett was second, and Mr. W. Brooks third. For a smaller group Mr. Somerhayes, gardener to H. Pethick, Esq., was a good first; and Mr. W. Brooks second.

Cut flowers occupied all the tabling round one large tent, and made a most attractive display. The Roses were remarkably fresh and good. Mr. J. Mattock, Oxford, was placed first for twenty-four varieties; second, Messrs. J. Townsend & Sons, Worcester. For twelve varieties Mr. T. Hobbs, Bristol, took the lead, with Messrs. Jarman & Co., Chard, second, and Mr. G. Garraway, Bath, third. The best twelve Teas were also shown by Mr. J. Mattock, Messrs. Townsend & Sons following closely; third, Mr. G. Garraway. Dahlias were well represented. Mr. G. Humphries, Chippenham, had a stand of twenty-four varieties in perfect condition, and was easily first; second, Mr. W. Smith, Kingswood; third, Mr. T. Hobbs. Mr. Humphries was also first for Cactus varieties, and Mr. W. Smith second. Gladioli, Asters, Hollyhocks, Begonias, hardy perennials, and Carnations were staged by many exhibitors. Epergnes were numerous and tastefully filled. Mr. W. Brooks was first, and Mr. W. A. Ford second. Mr. J. B. Brain, Clifton, had the best ornamental device in fruit and flowers, the second prize going to Mr. T. Meakin. Mr. W. Brooks exhibited a lovely hand bouquet, and was easily first; second, Mr. J. West. The table decorations by ladies found plenty of admirers, but would have been more effective if given more tabling. The prizewinners were Mrs. W. M. Appleton, Miss P. Tyte, Mrs. W. B. Lillington, and Miss Diana Phillips.

One tent was wholly devoted to fruit and vegetables shown by professional gardeners. There was a slight falling off in both quantity and quality, but the display was yet highly creditable. For a collection of eight dishes of fruit, Mr. J. Lloyd, gardener to Vincent Stuckey, Esq, Langport, was well first, showing good Black Hamburgh and Muscat of Alexandria Grapes, a Queen Pine Apple, a grand seedling Melon, highly coloured Bellegarde Peaches, and Pineapple Nectarines, Morello Cherries and Brown Turkey Figs. Mr. A. Crossman, gardener to J. Brutton, Esq., Yeovil, was second, and Mr. J. McCullock, gardener to J. C. Godwin, Esq., third. With four dishes, Mr. Crossman was first, showing Madresfield Court Grape, Windsor Castle Melon, Dymond Peach and Pineapple Nectarine, all in admirable condition. Mr. J. Lloyd was a good second. The class for Black Hamburgh Grapes was well filled. Mr. J. McCullock was first, and Mr. G. Sutton, gardener to W. A. Todd, Esq., second, both having good clusters. In the any other Black class, Mr. W. Carpenter, gardener to A. R. Baily, Esq., Frome, was first with well coloured, medium sized bunches of Madresfield Court; second, Mr. J. West, with the same variety. Mr. W. Carpenter took the lead in the Muscat class with well ripened Muscat of Alexandria, the second prize going to Mr. R. Mason, gardener to the Rev. A. J. Burr. In the any other white class Mr. J. Marshall led with extra good Buckland Sweetwater; second, Mr. A. Crossman. In the various other fruit classes the most successful exhibitors were Messrs. Crossman. Lloyd, G. Garraway, Kitley, Chedzoy, J. Hall, J. T. Hebditch, and W. Perryman. Both gardeners and cottagers made a fine display of vegetables.

The most noteworthy among the non-competitive exhibits was a fine bank of flowering and ornamental foliage plants, rock plants, new and rare Water Lilies, and cut flowers in great variety arranged by Messrs. R. Veitch & Son, Exeter.

MALTON.—August 11th.

The Malton (Yorks) Horticultural Society held its thirty-eighth exhibition in the Orchard Field on Wednesday, August 11th. The weather was beautifully fine and hot, but tempered by a nice breeze. We have seen better shows at Malton. The cut flowers and plants were very good, but the vegetables and hardy fruits were not up to the standard. Doubtless the very dry season has had much to do with this.

The class for six stove and greenhouse plants in bloom was won by Mr. Nicholas, gardener to the Marquis of Zetland, with Dipladenia profusa, Erica Irbyana, Statice profusa, Erica Austiniana, Anthurium Scherzerianum, and Allamanda nobilis. Mr. Kitchen, Darlington, was second. Mr. Nicholas was also first for three ditto, and Mr. Kitchen second. For six ornamental or fine-foliage plants the same exhibitors secured the prizes. Four good exotic Ferns were staged by Mr. Kitchen, they were Leucostegia immersa, Microlepia hirta cristata, and Davallia fijiensis plumosa. Mr. R. Wyse, Auburn Hill, second, who had a good specimen of Adiantum gracillimum. Orchids were a poor show. For three plants Mr. Kitchen was first, W. H. Pearson, Esq., second. Six plants for dinner table decoration brought several competitors, Mr. Kitchen first, Messrs. G. Longster & Sons second, Mr. Jas. Horsley third. Caladinms, Fuchsias, Liliums, Geraniums, and other plants were well shown.

The principal class amongst cut flowers was for twenty-four Dahlias. Messrs. Clark & Sons, Rodney, Leeds, had a very good exhibit; Messrs. Harkness & Sons, Bedale, being second. For twelve ditto Messrs. Clark and Sons were again first, Mr. H. W. Taylor second, and Messrs. Harkness & Sons third. For twelve Fancy ditto Messrs. Clark & Sons first, and Mr. Knight second. Mr. J. D. Hutchinson, Kirby Moorside, was first for twelve bunches single Dahlias, in threes. Messrs. Harkness and Sons staged splendid spikes of Gladioli. Messrs. Longster & Sons were first for twelve named varieties of Sweet Peas.

In the class for herbaceous flowers Messrs. Harkness & Sons had a good collection. Mr. J. D. Hutchinson was second. Mr. G. Cottam, jun., Hull, was first for a tastefully arranged bridal bouquet. Messrs. Longster & Sons second. In reversed order these two exhibitors secured the prizes for a hand bouquet. Mr. G. Cottam staged the most tastefully arranged vase of flowers for table decoration. Mr. T. Watson, Malton, second. Considering the lateness of the season Roses were well shown, Messrs. Harkness & Sons carrying off all the first prizes in the principal classes.

There was not a great quantity of hothouse fruit, but the quality was good. The first class was for four varieties, a silver medal, given by Mr. Spingelhalter, F.R.Met.Soc., being added to the first prize. There was only one entry, Mr. J. S. Upex, gardener to the Hon. H. W. Fitzwilliam,

staging Black Hamburgh Grapes, Princess of Wales Peach, Pitmaston Orange Nectarine, and Brown Turkey Figs. For three bunches of Black Grapes Mr. F. Nicholas was first with large, good-shaped bunches of Madresfield Court; Mr. Upex was second with smaller bunches, much better finished, of the same variety: Messrs. Longster & Sons third. In the corresponding class for white Grapes, Mr. Hughes, gardener to G. Woodall, Esq, Scarboro', was first with Muscat of Alexandria; F. Allen, Esq., Scarboro', second with the same variety; Mr. J. S. Upex third with Foster's Seedling. Mr. Wyse was first both for green-flesh and scarlet-flesh Melons; C. Cammell, Esq., second. The last-named gentleman was first for Apricots; Mr. J. C. Tate, Bulmer, second. For a dish of Peaches, Mr. R. H. Wiles first, Mr. Jas. Horsley second. Mr. Upex was first for Nectarines. Hardy fruit was not so good as usual, especially Apples and Plums.

There were three entries for a collection of eight vegetables, all being good. Premier honours were won by Mr. J. Whitehead, his collection comprising Cauliflowers, Carrots, Onions, Tomatoes, Potatoes, Peas, Celery, Cucumbers. Mr. Thos. Waite second, Mr. G. Cottam third. For three varieties of Peas Mr. F. Hoggarth was first, Mr. C. Wiseman second, G. N. Dawnay, Esq., third. Mr. R. Dobson, Malton, was first for six varieties of Potatoes, Mr. Geo. Howe, Brawby, second. Mr. C. Cammell was first for twelve Tomatoes, Messrs. G. Longster and Sons second, H. S. Richardson, Esq., third.

Messrs. G. Longster & Sons, nurserymen, Malton, staged a group of plants, not for competition, comprising Palms, Ferns, Lilies, Bamboos, Gloxinias, &c., interspersed with a quantity of good plants of Tuberoses. The cottagers' class contained some very creditable exhibits.

HASTINGS AND ST. LEONARDS.—AUGUST 11TH.

It would be difficult to imagine a more suitable place for a flower show than the Alexandra Park if the approach were more inviting. The above was a rather better show than usual, and we must especially note the stove and greenhouse plants, fruit, and table decorations. Mr. T. Portnell, gardener to Sir A. Lamb, Bart., Battle, was in fine form, and we did not notice his defeat in a single case of the many classes in which he competed. The following are only a few of the chief classes at what was certainly a good all-round show for the season.

Mr. T. Portnell was ahead for stove and greenhouse plants. Mr. A. Gadd, gardener to P. A. Eagles, Esq., followed. The same order was kept for six stove and greenhouse plants, and for a single specimen in flower. Mr. Cloves, gardener to G. King, Esq., was first for four stove and greenhouse plants. For eight variegated and ornamental foliaged plants, Mr. Portnell again led Mr. A. Gadd. These were both good lots and clean. For exotic Ferns Mr. Portnell was a good first, and Mr. Morris, gardener to C. J. Ebden, Esq, was ahead for four plants. Mr. Portnell won for Fuchsias, for six plants in flower and for both groups—miscellaneous and Ferns.

Mr. Portnell led for twenty-four varieties of stove and greenhouse cut flowers. Mr. J. Stredwick, Silver Hill, Hastings, was very successful among Dahlias, winning for twelve Show or Fancy, for twelve bunches of Pompons, and for a similar number of Cactus varieties. For twenty-four cut Roses, Mr. T. Durrant Young, Roselands Nursery, Eastbourne, beat Mr. R. E. West, Reigate, the blooms of the first stand being very fresh and bright, but rather small. Table decorations were a feature, all being light and tasteful. Mr. A. Notcutt, St. Leonards, won in the open class for three stands; and Miss Smith, St. Leonards, was ahead in that of three stands for ladies only.

Vegetables were good and far too numerous to mention, except as regards the open collection, which was secured by Mr. Langton Apps, Ore, for a good lot. . Fruit was numerous and of good quality. Eight competed in a class for three bunches of Black Hamburgh Grapes, Mr. C. M. Carter, gardener to the Duchess of Cleveland, Battle, just beating Mr. J. Gore, Polegate, but the latter was well ahead with Gros Maroc in the succeeding class for three of any other black variety, and also for three of Buckland Sweetwater. Mr. Gore's collection of eight dishes was good, the best being Violette Hâtive Peach, Hero of Lockinge Melon, and Madresfield Court Grapes.

There were several non-competitive groups, but those from Messrs. Cheal & Sons, Crawley, and Mr. J. Charlton, Tunbridge Wells, were the best.

CARDIFF.—AUGUST 11TH AND 12TH.

The Cardiff and County Horticultural Society held its ninth annual exhibition, on the above dates, in the Sophia Gardens. The weather was fine, and there was a large gathering on the opening day. This the genial Secretary, Mr. H. Gillitt, and the Committee deserve, and it is to be hoped the Show will prove a success financially, as it undoubtedly was horticulturally. On the whole the exhibition was a creditable one; but special mention must be made to the bouquets, wreaths, and the charming display made by the table decorations; these all came in for a large share of public appreciation.

There were three groups arranged to occupy a space of 100 square feet. Mr. R. McLew was successful in carrying off first honours with a light arrangement; Messrs. Case and Crossling being second and third in the order named. For the best group occupying a space of 50 square feet, there were four entries. Mr. McLew was again successful with a tastefully arranged group, Crotons, Liliums and Palms being used to advantage; Mr. Carpenter was second, and Mr. J. Hockey third.

For the best six specimen stove and greenhouse plants, Mr. J. Lockyer, gardener to J. C. Hanbury, Esq., Pontypool Park, was first with Statice profusa, Erica Holfordi, Ixora Williamsi, Stephanotis floribunda and others; Mr. Carpenter, gardener to W. J. Buckley, Esq., Penyfour House, Llanelly, second. For the best three, Mr. J. Clarke, gardener to Col. Sir Ed. Hill, took first place, and Mr. McLew, gardener to J. Gunn, Esq., second. In the class for six fine-foliage plants only two exhibitors staged, Mr. Wm. Carpenter was a good first, and Mr. R. McLew second. For six Ferns, Mr. R. McLew was first, and Mr. J. Clarke, gardener to Col. Sir E. Hill, second. In a similar class for four, Mr. Hockey, gardener to G. Rutherford, Esq., was successful, and Mr. R. McLew, second.

Fuchsias were represented by nice plants, not large but fresh and well flowered. Mr. T. Hibbard was a splendid first, Mr. J. Clarke second. Mr. T. Hibbard also took first place for the best four Fuchsias. For the best six Geraniums (Zonal) Mr. H. Rix, gardener to C. Waldron, Esq., Llandaff, was first, and Mr. T. Hibbard second. Mr. T. Malpas staged the best twelve Begonias, a very nice lot. Mr. T. Clarke second. The best single specimen stove plant was Clerodendron Balfouri, staged by Mr. Lockyer, Mr. T. Clarke taking second place with Allamanda grandiflora. The class for twelve table plants was represented by two lots only; Mr. T. Clarke was awarded first, Mr. G. Wall second. Mr. Clarke was first in a similar class for six. For the best collection of tuberous Begonias to occupy a space of not less than 8 feet by 5 feet, Mr. J. Vickery, gardener to W. Geen, Esq., was first with a good collection, Mr. G. Wall second.

Mr. R. Crossling, Penarth, won first honours for twelve varieties H.P. Roses, three blooms of each; Mr. S. Treseder second. In the class for thirty-six Teas, in twelve varieties, Mr. S. Treseder was first; Mr. Crossling second. The last-named exhibitor was first for twenty-four, distinct; Mr. S. Treseder taking second place. Mr. Crossling was a good first for eighteen Teas, distinct; also for twelve Teas, any one variety, staging nice blooms of Maréchal Niel. Messrs. Townsend and Sons were first in the class for twelve H.P.'s, in one variety, with Mrs. J. Laing.

Messrs. Keynes, Williams & Co., Salisbury, were a good first for twelve bunches of Cactus Dahlias; and Mr. Wm. Treseder second. For the best twenty-four Show Dahlias the same exhibitors were successful, both staging fine blooms. Mr. Lockyer, Pontypool Park, was first for twelve bunches of stove or greenhouse cut flowers; Mrs. H. A. Smith second.

Dessert tables are always a feature at Cardiff, and the several arrangements at this Show proved no exception to the rule. For the best table, 8 feet by 4 feet, arranged with fruit and flowers, and laid for eight persons, Messrs. Case Bros., Queen Street, Cardiff, were a good first with a very bright and gracefully arranged exhibit. Messrs. Phelps & Co. were second. For the same arrangement, open to amateurs, Miss F. W. Jenkins was awarded the first prize, Miss Mabel Hill and Miss Rose Crouch second and third. Mr. A. Robinson was awarded first prize for the best arranged vase for table decoration. Bouquets, wreaths, and crosses were superb. Mr. A. E. Price took first place for the best bouquet for the hand; Messrs. Case Bros. second, and Mr. Wm. Treseder third. Messrs. Case Bros. and A. E. Price took first and second honours for a bride's bouquet. Messrs. Case Bros. were first for the best wreath, and A. E. Price for the best cross.

For the best six bunches of Grapes in three varieties Mr. R. Grindrod, gardener to P. S. Phillips, Esq., Hereford, was a good first, staging Gros Maroc, Black Hamburgh, and Bowood Muscat. A silver challenge cup is given in this class; Mr. Grindrod winning last year, the cup becomes his property. Mr. E. Silk, gardener to T. M. Frankler, Esq., second. The last named exhibitor took first for three bunches of Black Hamburgh; Mr. Gilbert Davidson second with smaller bunches, much better in colour than the first prize lot. For Muscats Mr. Wm. Hockey was first, and H. Pitt, Esq., second. Mr. Grindrod staged three good bunches of Gros Maroc for any other black; second, Mr. E. Silk. The last named was first for the best three bunches of white with Foster's Seedling, Mr. H. Townsend second. For the best green or white fleshed Melon Mr. E. Silk was first, and Mr. T. Malpas second. The Bishop of Llandaff was first with scarlet flesh Melons, showing a fine pair; and Mr. H. Townsend first for green or white fleshed; and the Bishop of Llandaff was first for the best scarlet fleshed.

In the class for the best six dishes of dessert fruit Mr. R. Grindrod was a good first with Black Hamburgh Grapes, Royal Favourite Melon, Bellegarde Peach, Lord Napier Nectarine, Early Large Apricots, and fine Brown Turkey Figs. H. Pitt, Esq., was a fair second. Mr. J. Hockey was first for six dishes of dessert Apples, and Mr. J. Bosham, Bassaleg, second. In the corresponding class for culinary the order of the prize-winners was reversed. Mr. R. Grindrod won for Peaches with fine Bellegarde, and Nectarines with nice fruit of Lord Napier. H. Pitt, Esq., was first for Pears and Cherries, also Plums.

Vegetables were not staged in such large quantities as at previous shows, but quality was not lacking. For Messrs. Sutton & Sons' special prize there were five stands. Mr. C. Foster, gardener to Morgan S. Williams, Esq., Aberpergwm, Glyn Neath, was first, showing Selected Ailsa Craig Onion, Solid White Celery, Best of All Runners, Windsor Castle Potatoes, Autumn Mammoth Cauliflower, and Perfection Tomato; General Lee second, and the Right Hon. Lord Aberdare third. Mr. C. Foster also won the prize given by Messrs. Webb & Son with Mammoth Red Celery, Early Mammoth Cauliflower, Regina Tomatoes, Eclipse Runners, Masterpiece Onion, and Goldfinder Potatoes. He was again first in the open class for nine vegetables, Mr. G. Shewring second. Collections of Potatoes were well shown by Mr. C. Foster, Mr. Townsend being second, and Mr. Jenkin Morgan third. Leeks were staged by Mr. Townsend, Mr. Foster winning with Carrots and round Potatoes, and Mr. Wm. More had the best dish of kidneys.

Messrs. Wm. Clibran & Son staged a very pleasing exhibit of hardy

cut flowers, including a fine lot of Violas in variety, Niphetos, Dorothy Tennant, Duchess of Fife, Picotee, Duke of Edinburgh, Colleen Bawn, and many others being very fine. Mr. H. Eckford made a fine show with a beautiful stand of Sweet Peas.

EPSOM.—AUGUST 12TH.

THE second annual exhibition of this Society, which was originally formed to give encouragement to allotment holders and cottagers, and now also includes classes for gardeners and ladies, was held in the grounds of Woodcote Hall, the residence of C. F. Murray, Esq., on this date. Honorary exhibits included from the nursery of Messrs. Morse and Son, Epsom, some noble Palms, used with good effect, down the centre table, and groups of Cannas and other plants. Mr. Glover, gardener to the Rev. E. W. Northey, showed a good group of Lilium lancifolium, Hydrangea paniculata, and Pancratiums. Mr. Will Taylor, Hampton, had excellent Roses; and Messrs. J Cheal & Sons, Crawley, put up a large collection of hardy flowers and Dahlias.

The best decorative groups of plants in competition came from Messrs. A. Bridges, gardener to A. Wales, Esq.; and Buss, gardener to A. G. Soden, Esq., both being gay. Mr. Buss staged the best six Begonias, and Mr. Bridges had the best six plants in and out of flower; Mr. Buss being second. The only exhibitor of twelve Cannas in pots and in bloom was Mr. Heslinbury. These, however, need to be stood on the ground and have a carpet of Fern to render them pleasing. In the ladies' class for dinner table decoration there was strong competition, and some very crude and very pleasing combinations were seen. The judgment of three ladies, as is customary, evoked profound dissatisfaction. The first prize was given to Miss Sterling for a rather heavy arrangement of the national colonrs red, white, and blue in scarlet Pelargoniums, blue Cornflowers, and flowering wild Parsley, and the garden Carrot. Miss Pettitt had a beautiful table of medium-sized soft coloured Roses with long drooping shoots. Lady Evans had one not less pleasing of rose-coloured Carnations and Gypsophila paniculata, and another had flowers of Gloriosa superba with Gypsophila. Mrs. P. Ralli set up a centrepiece of fine fruit from Ashtead Park, and she also obtained the first prize for hand bouquet of Orchids.

Some of the baskets shown, notably one of Gloxinias, Fern, and Smilax, were charming. Mr. Haseman, gardener to W. E. Bagshaw, Esq., had the best black Grapes in really finely finished Muscat Hamburghs; Mr. Osman, gardener to W. B. Braithwaite, Esq, coming second with good Black Hamburghs. In the white Grape class Mr. Bridges was first, and Mr. Osman second, both having Muscat of Alexandria. Mr. Turner, gardener to C. F. Murray, Esq., had the best four dishes of tender fruit in good Grapes, Peaches, Melon, and Jefferson Plums, and was also first with four dishes of hardy fruit. Mr. F. Tye, gardener to the Rev. J. Hart-Smith, had the best dishes of Apples, his Prince Albert being exceptionally good. There was good competition in all the cottagers' classes—indeed, in many cases exceptionally so, much more room being needed. This could easily be furnished by the adding of more tables to the centre one. Some sports on the lawn were provided during the afternoon, but these seemed to be too exclusive and *dilettante* to afford much pleasure to the general body of visitors who crowded the place later.

TAUNTON.—AUGUST 12TH.

THE Taunton summer exhibitions, of which thirty have now been held, are invariably popular. On the occasion under notice the entries were more numerous than usual, and it was equally satisfactory to note great crowds of visitors thronged the Vivary Park in which these shows are held. Mr. John S. Winsor makes an excellent Secretary, and he is ably assisted by a large Committee of leading townsmen.

In the premier class for twelve stove and greenhouse plants in flower, the prizes are respectively £20, £15, and £6, but these only attracted two exhibitors. Mr. J. Cypher, Cheltenham, won the first prize with grandly flowered specimens of Phœnocoma prolifera Barnesi, Bougainvillea glabra, B. Cypheri, Allamanda Hendersoni, A. nobilis, Erica Austiniana, E. Aitoniana, Ixora salicifolia, I. Prince of Orange, Statice intermedia, and S. profusa. Mr. W. Rowland, gardener to W. Brock, Esq., Exeter, took the second prize with an even and fresh collection. Similar positions were held by these exhibitors with six plants in flower, and also fine-foliaged plants, both showing grand specimens. Mr. Cypher was the most successful in the classes for single specimens, but had to take second place for six Orchids, Mr. J. Thomas, gardener to W. G. Marshall, Esq., Taunton, winning first prize.

In the classes for Tuberous Begonias, Gloxinias, and other plants, the principal exhibitors were Mr. J. Thomas; Mr. W. H. Bruford, gardener to S. Bennett, Esq.; Mr. H. Godding; Mr. C. Cooper, gardener to W. McAdam Smith, Esq.; Mr. J. Crossman, gardener to Col. Mount Batten, Yeovil; and Mr. S. Dight, gardener to the Rev. D. J. Pring. For a large group arranged for effect Mr. W. Rowland was first; Mr. W. Peel, gardener to Miss Todd, Southampton, second; and Mr. V. Slade, third.

Amateur growers, that is to say all who are not nurserymen, are capable of filling one large tent at Taunton with their exhibits, and did so worthily on this occasion. For twelve stove and greenhouse plants Mr. W. Rowland was first, and Mr. W. Peel second. For six plants Mr. Thomas was first. Mr. Rowland second, and Mr. S. Kirle, gardener to A. Sandford, Esq., third. Mr. Peel staged the best six plants with ornamental foliage, and Mr. Rowland was first for six exotic Ferns. Mr. Thomas was well first for four Orchids, and the best six pots of Japanese Lilies were shown by Mr. C. Cooper, gardener to W. McAdam Smith, Esq. Tuberous Begonias were grandly exhibited in this tent, Mr. Thomas having to be content with the second prize for double varieties, but was first for six single-flowering sorts. Mr. S. Dight, gardener to the Rev. D. J. Pring, being well first for doubles and second for singles.

Anything like a detailed account of the exhibits of cut flowers was out of the question owing to the crush. In the open class for thirty-six Roses, distinct, Mr. J. Mattock, Oxford, was first; Messrs. Townsend and Sons, Worcester, second; and Messrs. Jarman & Co., Chard, third. Similar positions were occupied for eighteen varieties. The best twelve blooms of Dahlias were shown by Mr. G. Humphries, the second prize going to Mr. T. Hobbs, Bristol, and the third to Messrs. T. Townsend and Sons. Mr. Humphries was first with twelve Fancy Dahlias, and Mr. W. Smith, Kingswood, second. Mr. Smith was first for Cactus and decorative varieties, Mr. Humphries first for Pompons, and Mr. J. Burgess, Bath, first for single flowering Dahlias, the competition being keen in each instance. In the amateurs' tent there was another fine display of cut flowers.

Six competed in the class for a dining table, arranged with decorations of fruit and flowers laid for eight persons. Mr. J. Cypher was first, Mrs. Anderson second, Miss L. E. Lock third, Mrs. McAlister fourth, Miss Currey fifth, and Miss P. Tyte highly commended. The taste displayed throughout was good, but Mr. Cypher's flowers and fruit were extra choice, and the arrangement fairly light. Messrs. J. Scott & Co., W. H. Coles, and Hayward Brothers were respectively first, second, and third for hand bouquets, and there was also a good display of ladies' sprays and gentlemen's buttonhole bouquets.

Fruit was not quite so extensively shown as usual, nor was the quality so good as in former years. The best collection of eight dishes was shown by Mr. J. Lloyd, who had well coloured bunches of Black Hamburgh and Muscat of Alexandria Grapes, a very fine seedling Melon, Bellegarde Peaches, and Pineapple Nectarines, Brown Turkey Figs, Quarrenden Apples, and Morello Cherries. Mr. A. Crossman, gardener to J. Brutton, Esq., Yeovil, was a good second, and Mr. W. Seward, gardener to Sir J. D. Ferguson Davie, Bart., a creditable third. For four dishes Mr. A. Crossman was first, showing well finished Madresfield Court Grapes and remarkably good Melon, Peaches and Nectarines. Mr. Lloyd was a close second, and Mr. Webber, gardener to G. F. Luttrell, Esq., third. Mr. Lloyd had the best three bunches of Black Hamburgh Grapes, Mr. Crossman following closely, while in the class for any other black variety Mr. W. Cheater, gardener to Sir W. Paily, was first with Madresfield Court, the second prize going to Mr. C. Cooper. Mr. Lloyd was first for well ripened bunches of Muscat of Alexandria, and Mr. W. Cheater second. Very good bunches of Buckland Sweetwater gained Mr. Webber the first prize in the class for any other white variety, the second prize going to Mr. C. Williams, gardener to C. D. Harrod, Esq. Mr. Lloyd staged the best Melon, a seedling of his own raising, the Frome Flower and Fruit Company the best Peaches, Mr. Crossman the best Nectarines, Mr. Webber the best Apricots; Mr. T. Somers, gardener to J. T. Hebditch, Esq., the best culinary Apples; and dessert Apples, Cherries, Plums, Gooseberries, and Currants were also fairly numerous and good in quality.

Vegetables were remarkably good and abundant. Mr. T. Wilkins, gardener to Lady Ivor Guest, Henstridge, was well first for a collection of eight varieties, showing fine examples. Mr. T. Harrison, gardener to Major Aldworth, Yeovil, was a good second; and Mr. W. Squire, gardener to C. J. Elton, Esq., third. Special prizes for collections were offered by Messrs. Webb & Son, Jarman & Co., and Sutton and Sons; Mr. T. Wilkins taking the first prize in each. Potatoes, Tomatoes, Onions, and other vegetables in season were admirably shown in the various single dish classes.

Non-competitive exhibits were numerous, and added considerably to the attractiveness of the show. The most prominent were those of Messrs. R. Veitch & Son, Exeter; Messrs. Jarman & Co., Chard; and Messrs. Kelway & Son, Langport.

THE YOUNG GARDENERS' DOMAIN.

MUSHROOMS FOR WINTER.

OF late years the value of this edible fungi has become more and more recognised, and in the majority of gardens provision is made for its cultivation in Mushroom houses. These houses are usually built in a position where the direct rays of the sun do not fall upon them. The inside is fitted with beds made of wood, iron, or slate, the latter being most suitable. These beds are usually about 3 feet wide, 6 feet long, and 1 foot deep, supported on pillars, and are usually three tiers high. Windows ought to be provided also, and these fitted with shutters so that light may be excluded when no one is working in the house. In such structures it is only advisable to attempt to grow Mushrooms during the late and early months—*e.g.*, commencing spawning early in October and concluding in March, for in the summer months the temperature of the house is too high and the atmosphere too dry for the crops to come to perfection. Stable litter is indispensable for making the beds, and it is easily procurable where several horses are kept in stalls or boxes.

Place the litter in a heap until the requisite quantity is obtained, and spread it in an open shed about 1 foot thick to allow the steam to escape. The long litter must be taken away from the manure; still, sufficient ought to be retained to prevent the bed becoming too solid, for when in that state it will hold too much water and become sodden, which is injurious to the extension of the spawn, and consequently prejudicial to the crop of Mushrooms. We turn the manure daily for nearly a fortnight, when it is sufficiently decomposed and sweetened for the purpose

for which it is intended. It is then placed in the beds, ramming it as firmly as possible.

When this has been done insert a "dipping" thermometer, and after the temperatnre has reached its highest point, and receded to about 80°, the bed may be spawned. Break the spawn into lumps about 2 inches square, and insert them 2 inches deep in the manure at a distance of 6 inches apart. Two or three days afterwards give a covering of fine loam an inch thick, making this level and firm by beating with a spade. With the manure properly moist, as it ought to be when used, the beds will not require watering. The surface soil must always be kept moist, and this can be done by a light covering of litter and occasional syringings. The paths and walls of the house must also be kept well damped. Keep the temperature of the house about 55°, dispensing with fire heat as much as possible. Mushrooms usually appear from five to six weeks after spawning, and the beds continue productive for two or three months.—ELVEDEN.

THOUGHTS ON COLOUR.

SOME praise the forms of flowers, others delight more in fragrance. and all enjoy their many tints and varied colours. We shall strive of course in this respect to please everybody, and have lovely forms, deliciously odoured, and pleasantly coloured joy givers. In the darkness of a black midnight hour have you ever paused in contemplation of the awfulness if such blackness never lifted? With these thoughts our thanks of gratitude go up for the good light of day and wisdom to see the beauties suffused through earth in a thousand hues.

Unchanging, yet ever pleasant, is the universality of greenery spread out in grassy lands and swaying foliage, and the restful blue sky, enlivened by clouds, shaded with tints undescribable. The reasons assigned for the preponderance of the soft ground-colour green are readily apparent and conclusive. It is of all colours the most restful to our eyes. It is quiet and sober, but not dull, harmonising or contrasting acceptably with most other shades or colours.

Green is a mixture of blue and yellow. Red, blue, and yellow are primitive colours and cannot be got by admixture. Purple is a union of red and blue; orange, of red and yellow, and so the list proceeds. Black or white are not strictly colours, yet a ray of sunlight seen through a prism gives a seven-coloured spectrum band of colours. These are red, orange, yellow, blue, green, indigo and violet colours of the rainbow.

It is by the aid of the prism that the chemical elements of any substance from the sun itself down to tobacco ash can be unfathomed. Long and patient labours by chemists have proved that all chemicals which burn give a characteristic colour or invariable breadth of line (when seen through the prism) on the spectrum. By careful observation of these lines, colour, breadth, and position the elements are found and named. As stated previously, the prism dissects the seven colours composing white light. Each colour shoots upward more or less, red least so, violet most, the others between. The red light is often seen at sunrise and set. Before the sun comes in view some few rays are striking the clouds which act like a prism, and red light suffuseth them, it being lowest in the order of refraction.

In explaining how flowers are coloured, Dr. Brewer states that according to the constitution of different petal surfaces divers lights are reflected, and give to our eyes the characteristic hues seen in flowers. A Rose was red because that ether—a subtle fluid supposed to permeate space—undulated so many millions of times per second on the surface exposed. Greater or less speed of undulation on various petal surfaces gave other colours. These colours were compared to a scale of music in which deep red or bright red might be likened to lower "C" or "E;" stringed or wired instruments to produce those sounds having to vibrate at the same rate as that which gave the red or other colour to the Rose.

In Professor McNab's small class-book of botany we find the statement, "In many of the higher plants a red sap exists in the epidermal cells, concealing the chlorophyll cells below." This shall, of course, refer to foliage. Coloured crystalloids are met with in petals. I have a book on "Gardening" written by a clergyman so long ago as 1714. In a chapter on "Budding" he relates "of a noble discovery by virtue of inoculation." He took a bud "from the yellow striped Jessamine," inoculating it "in a plain Jessamine tree," and states that every shoot gradually became yellow "by virtue of the circulation of the sap." (Sap circulation was at that time doubted by many.) One hundred and eighty-three years have passed since then, and do we yet know satisfactorily the causes of leaf variegation?

The grouping and harmonising of colour is a matter of importance among gardeners. Mr. Loudon, in his works, advocates for unity of expression massings, reasoning that mixed arrangements confuse the vision and disturb the sense of repose. On the other hand, William Wildsmith, Shirley Hibberd, and Charles St. J. Smith unite to praise the mixed style. For myself, I prefer the massing system, it being predominant in Nature, and most impressive and lasting. Linnæus, noble man, on seeing an English common all ablaze with yellow Gorse, was so affected that he fell on his knees with tearful eyes and thanked God for so glorious a sight.

Whatever laws apply to garden arrangements, different ones are practised in floral-work decorations. In Miss Malling's work on "Flowers, and how to arrange them," advice is given on colour choosing. "In floral groups there should be no conspicuous colour—nothing unduly prominent." Ground colours must be studied, and colours chosen which are proved to harmonise. "In all arrangements in which white comes in so suitably, a caution is very necessary against its too frequent use, though it is a tempting means of separating antagonistic colours. White is so poverising, that even brilliant colours are made poor and trivial by its superabundance." It is cold and chilling. "In groups of white a little colour gives tone and relief."

Harmonising colours are: "Rose with a *little* blue; blue with a little rose; white with mauve or lilac, and sometimes a little primrose; dark purple and primrose; cerise or scarlet and white; blue shaded, with a mixture of white and rose; rose shaded, also with blue and white;" brilliant yellow and deep black. These are charming.

The flowers themselves should be light and free, using heavy masses mainly for distant effects. Dark green is usually most appropriate with purely tinted heavy flowers. Grass green is superb in artificial light. It is worth one's while to note the changes wrought on colours by altered lights; some are brilliant, others soft, all are somewhat affected. I have been vainly trying to understand how "stained" glass sends forth a light coloured like itself. It must be by polarisation, and polarisation is a change produced on clear light by a series of reflections or transmission through crystals. (Crystals are bodies of any colour, generally angularly shaped.)

The colours of many flowers require to be peered into, studied, and reasoned. If we have a cross or union of two colours then at once—when describing—mentally reason whether this colour or that, united, would produce a hue like the one before you, and thus till satisfied. Practice alone will make perfect. If you wish to be a good gardener, and raise the profession, then you must consider the subject of "colour" in its many bearings. Write out the names of every colour you have heard or read of, and then, as "An Old Boy" says, "Be inspired to know" and remember their individuality and harmonious arrangement.—A YOUNG SCOT.

FRUIT FORCING.

Cucumbers.—Old plants, whether in houses, pits, or frames, which have been bearing from an early part of the season, produce fruit about this time, or soon afterwards, knobby ended, and essential as these are for seed, they are indifferent for use. Besides, seed bearing is fatal to the production in quantity of useful fruit. Old plants, however, may be kept in a bearing condition by cutting out the old growths and encouraging young, so as to insure a succession of bearing wood, yet the fruit is more or less liable to come knobbed. Train the young growths thinly, removing old leaves to afford room for new growths, and stop at one or two joints beyond the fruit. Remove the surface soil where it can be done without injury to the roots, and supply fresh lumpy loam. Plants in frames that have been bearing some time will be restored to vigour by a free thinning out of the old growths and the addition of a little fresh loam, giving a moderate watering and a sprinkling over the foliage on fine afternoons, closing at about 3 P.M. With linings to the beds, and the protection of mats over the lights, Cucumbers will be produced for a lengthened period.

Autumn-fruiting Plants.—When a supply of Cucumbers is wanted in late summer and autumn young plants afford them much better than old ones, either in frames or houses. Therefore, the plants raised some time ago and planted out should be encouraged to make a strong growth by earthing the roots betimes, applying enough soil each time to cover those protruding, and taking care to have the soil moist and warm. Supply water to the roots only when wanted, and give a thorough supply each time. Syringe about 3 P.M., damping in the morning, at noon and in the evening in bright weather. Maintain a night temperature of 65° to 70°, 70° to 75° by day artificially, 80° to 90° from sun heat, and close sufficiently early to rise to 90°, 95°, or even 100°. Train the growths rather thinly, allowing about 12 inches between the side growths, and stop them about every foot's growth to give the needful fruiting and furnishing shoots. Remove all fruits and male flowers as they show so as to induce a sturdy habit, the beginning of September being sufficiently early to allow fruit to show for cutting at the end of the month, then by cropping lightly fruit will be had in full supply later on, when it is most wanted; the plants, however, will give fruit from the early part of September if desired, and not being over-burdened, keep up a succession till the new year or longer. Avoid overfeeding, as it only induces fungoid diseases and favours root eelworm attack. Secure plenty of roots by sweet compost, and sturdy growth by top-dressing of fertilisers and judicious ventilation with full exposure of the foliage to the light.

Houses for Winter Fruit.—The structure must be light and efficiently heated both at top and bottom, and means of ventilation be provided so that air can be admitted when necessary without creating a prejudicial draught. The plants will have been raised from seed, say about the 10th of this month. Pot the plants as soon as ready, keep them near the glass, transfer into larger pots as they require more root space, and place a small stick to each for its support, growing the plants without stopping, but rubbing off side shoots as they appear to the height of the trellis. In the meanwhile the house should be cleansed and repaired or painting completed. Remove all the old soil, and make everything as sweet as possible, so that the plants may have a chance.

Winter Cucumber growing is much easier to write about than to practise successfully.

Figs.—*Earliest Forced Trees.*—For the earliest crops, trees in pots are the most suitable, and the most reliable varieties are Early Violet, St. John's, Pingo de Mel, and Brown Turkey, as they give the best returns and are surest in the first crop. The trees may now be planted outside if the wood be ripe; but if there is any doubt about it, continue them under glass with a free circulation of air. These are matters on which the cultivator will need to exercise judgment. In either case the trees must not suffer for water at the roots, and any of these extending beyond the pots should be cut off, affording water only to keep the foliage fresh.

The earliest forced planted-out trees will now be ripening the young wood, and air may be given very liberally, watering being confined to keeping the foliage from becoming limp. If, however, the second crop is not yet ripened, moderate in the soil, and even atmosphere will be necessary, with a free circulation of air to insure high quality in the fruit. When the fruit is all gathered, the wood not further required should be cut away in favour of the successional growths, and these being allowed to point towards the light will become well matured at their extremities, which is the chief thing to secure a full first crop another season.

Unsatisfactory Trees.—If any of those planted out in house grow too rampantly, root-pruning should be resorted to and the roots confined to a narrow border not more than half the width of the trellis, grand crops being had from trees in 3 to 4 feet width of border. But to secure a satisfactory first crop another season it is necessary to thoroughly ripen the wood. Trees, therefore, which are unsatisfactory in cropping should have a trench taken out as deeply as the roots, at a distance of 3 or 4 feet from the stem, and all the roots being detached the tendency to a late growth will be checked, and the wood will ripen if thinly disposed, and the points of the shoots allowed to grow up to the light instead of being closely tied down will form embryonic Figs. This should be attended to as soon as the fruit is gathered, and the trees may be lifted as soon as the leaves give indications of falling, replanting in fresh soil. If the drainage be defective, place in 12 inches of rather rough brick rubble, and 3 inches thickness of old mortar rubbish, using the finer parts to the extent of a fifth with the soil, which may consist of any good, rather strong, but porous loam with a fair amount of grit or small gravel in it. Incorporate thoroughly and ram the soil well in replanting the trees so as to secure short-jointed wood. A dip of 24 inches suffices, or if the border be somewhat wide, 18 inches. Where the drainage is efficient and the border in good order, it will only be necessary to confine the roots to the narrow border, removing some of the old soil from amongst them, relaying them in fresh soil, or even the old, with an addition of old mortar rubbish well solidified.

Late Houses.—In wall cases the fruit ripens about this time onwards into September. Brown Turkey stands unrivalled for general purposes, but Brunswick, where there is room, cannot well be beaten, and a similar remark applies to White Marseilles. The great point to aim at is sturdy growths, securing them by keeping thin and the roots restricted to a border of compact materials. Unless thoroughly solidified growths are made it is useless expecting abundant crops of fine fruit; it only comes on short-jointed, well-ripened wood. Keep up a circulation of air constantly, expose the fruit as much as possible to the sun, and afford no more water at the roots than sufficient to keep the foliage in health. If the trees are too luxuriant and the wood does not ripen, treat them as advised for unsatisfactory trees.

Melons in Houses.—The plants require less water as the days shorten, only giving sufficient to keep the foliage healthy and the fruit swelling. When this is completed afford no more than to keep the leaves from flagging. Stop laterals to one leaf on successional growths, rub off all superfluous shoots as they show, thin the laterals where crowded, not allowing them to interfere with the principal leaves or to retard the swelling of the fruit. Plants with fruit advanced for ripening should be kept drier at the roots and have air liberally, avoiding a close atmosphere, as that frequently results in the fruit cracking, and generally causes the flavour to be inferior. Keep the night temperature at 65° to 70°, 70° to 75° by day artificially, and 10° to 15° rise from sun heat. Place out the latest plants without delay, and give every encouragement.

Plants in Pits and Frames.—The latest Melons are set and swelling, and will be the better for good linings to the beds, so as to insure steady progress and the free admission of air. Those in hot-water heated pits will be the better for a gentle warmth in the pipes on cold nights and on dull days. Gentle warmth in the pipes affords facilities for ventilation, a little being given to insure elaboration of the juices. The plants may be sprinkled on fine afternoons, always early, avoiding the stems or collars, and closing before the temperature has receded to 80°, so as to raise the heat to 90° or 95°, or even 100°. Admit a little air at 75°, increase it with the advancing sun heat, and keep through the day at 85° or 90° by that means. Employ covering over the lights on cold nights, but remove early in the morning, so as to let the sun act on the frames or pots and thus secure a long day's work.

PLANT HOUSES.

French and Fancy Pelargoniums.—Plants that have hard, well-ripened wood may be pruned back closely, and stood in a frame until they commence growth. If they are syringed twice daily, and the frame closed early in the afternoon, they will soon start, and no water will be needed at their roots before they reach this stage. When they have well broken into growth the old soil may be shaken from amongst their roots and the plants repotted in a smaller size. The soil may consist of good loam three parts, one part leaf mould, one-seventh decayed manure and sand. Syringe lightly and water carefully until they commence rooting freely into the new soil. The frame may be kept moderately close at first, then admit air abundantly to insure sturdy growth. Young plants that are just rooted in small pots may be placed into 4½-inch pots. Give abundant air from the first, but water carefully, and they will soon commence rapid growth. Cold frames are the most suitable structures for them, so that the lights can be thrown off after active growth has commenced. Good cuttings may still be inserted in sandy soil, and stood in cold frames until they are rooted.

Roman Hyacinths.—For early flowering bulbs may be potted at once. They can be placed thickly together in pots, pans, or boxes, according to individual requirements. We have found them to succeed well in equal quantities of old refuse soil from the potting shed and good loam, to which is added leaf mould, sand, and a little decayed manure. The bulbs after they are potted should be placed outside and covered with ashes 4 inches deep. Select for them a position moderately sheltered from the sun, as when fully exposed the soil in the pots is liable to become too dry. Bulbs may be potted at intervals of three weeks until the end of October.

Snowdrops and Crocuses.—Where these are required to flower early they should be potted at once, and not delayed until October and then subjected to undue forcing in spring. Failure is certain to follow such a course of treatment. If home-grown bulbs are prepared for this purpose where they do well, and are potted now, it will be found that the pots are full of roots by the time imported roots can be obtained. These, if never removed from cold frames, will precede those outside in flowering.

Primulas.—All but the latest should be in their largest pots. Be careful to grow them on a cool moist base where they can be protected from strong sun, but where they can enjoy abundance of light. Provide ventilation most liberally to insure sturdy growth. These plants are frequently spoilt by keeping them too close; they draw up weakly, and are a prey to damp in autumn. Give the earliest plants soot water in a clear state, and a little artificial manure on the surface once a fortnight. Double varieties should also be in their largest pots. These do better close to the glass where they can be shaded from the sun provided they stand on a bed of ashes or gravel.

Petunias.—Plants for early flowering in 5-inch pots next season may be rooted at once and then transferred to 3-inch pots. After they are rooted pinch out the points to induce them to branch, and grow them as cool and sturdily as possible. Any good varieties from amongst the seedlings that were raised in spring may also be perpetuated by cuttings inserted at the present time. The cuttings of Petunias are liable to damp if they are placed in too warm and too close a structure. A cold frame, that can be kept shaded, will be found the best place for them.

Fuchsias.—Cuttings of these may also be inserted now, and they root freely in cool frames if dibbled thickly into boxes. They should be potted singly after they are rooted, and encouraged to make firm growth by potting them moderately firm and growing them as cool as possible.

THE BEE-KEEPER.

The Weather.

The bright weather experienced throughout the country during the whole of July and the first week in August has had the effect of drying the pastures, and little honey has been obtained from the second crop of white Clover. It is many years since the pastures in this locality (South Yorkshire) have been parched so badly as at the present time; nor is this to be wondered at when we take into consideration the deficiency in the rainfall. During the month of July less than three-quarters of an inch was registered, in marked contrast to what is usually our wettest month; the temperature, too, being much above the average. On several occasions the maximum shade thermometer registered 86°; but at noon on the 5th inst. the highest shade temperature recorded for many years was reached—namely, 91°. The heat was almost unbearable. Some combs that were exposed to the sun were quickly melted; hives were all shaded, and free ventilation was given at the entrances. It is during a spell of hot weather when the advantage of having loose floor boards to all the hives is fully appreciated, as the bee-keeper is then enabled to wedge up the front of all hives, and thus provide ample ventilation; but even with full air space and shade it is surprising the combs are not more often melted than they are. The bees, however, keep up a circulation of air by fanning at the entrance.

Since the above date there has been heavy thunder locally, but very little rain. The temperature is now lower, but the days are fine and bright. The bees are busy storing what the country people call honeydew, being mostly caused by the aphides, which at this season infest the foliage of many of our hardy

trees, and which is always worse after a few weeks of dry weather. Bee-keepers will now have removed the surplus from their hives, so no harm will be done in spoiling a good sample of honey, which it would do quickly. There is no means of preventing the bees from carrying this secretion into their hives, but if stored in large quantities I am inclined to think it will often cause dysentery.

Breeding Bees in the Autumn.

Bees that are properly attended to will derive much benefit from the continued fine weather, as they are well-supplied with stores for their present requirements. This will have the effect of keeping the queen laying throughout the autumn, or as long as the fine weather lasts. It is well for bee-keepers to bear in mind that the bees hatched now and onwards for the next two months are the worker bees that will be alive and doing the work of the hive next spring—not the bees that have been hard at work for the past six or eight weeks, and are now worn out. These may be found crawling in all directions in the neighbourhood of the hives, unable to rise on the wing, and so become a prey to the birds and toads and other enemies. It is easy to detect the old worn-out bees by their bright and polished appearance, and if steps are not taken to provide numerous young ones to take their place, a colony composed chiefly of old bees must end in disaster.

Owing to the excessively wet weather experienced last autumn very few young bees were hatched, as the queens stopped laying earlier than usual. The result was stocks gradually dwindled. The consequence was more dead stocks were chronicled last spring than has been the case for many years past. From observations made in years past I have always found the bees came out stronger in the spring after a fine dry autumn than a wet one, the winter being only a secondary consideration, as it is not the cold that kills the bees. If a stock is examined that has succumbed it will often be found to have been headed by an old queen, or the hive was damp, or insufficiency of stores was the cause of the disaster.

Whether bee-keepers use large or small hives they should bear in mind that colonies headed by young fertile queens, surrounded by numerous young bees, and well provided with stores in a damp-proof hive, is the most favourable condition for them to be in at this season.

Drones still in Hives.

When drones are observed in hives at this date it is a pretty sure sign that the stock is queenless, or that something is wrong with the queen, either from age or infirmity. When this is the case, steps should at once be taken to examine the stock, and if found to be queenless unite the bees to another colony, according to instructions given in previous notes. It is too late to rear young queens after this date—not that it is impossible, but there are so many chances against their doing well that it is much better to err on the side of safety, and unite the bees; or if it is a strong stock it may be requeened. Queens may be often obtained from driven stocks or other sources. A strong healthy colony which is headed by a prolific queen invariably kills the drones directly the honey flow is over.

If on examining a stock containing drones a queen is found and only a few eggs are being laid, if her wings are ragged and she is slow in her movements, she is an old queen, and should be superseded. When experimenting with queens of three or more years old I often found the worn out queen in the hive where drones were observed late in the autumn. I now rarely keep a queen more than two years, as the extra labour entailed in rearing young queens is well repaid; but it is as well to look on a hive containing drones at this season with suspicion.—An English Bee-keeper.

Messrs. Clay & Son.—We have received a notification stating that the partnership heretofore subsisting between Mr. Samuel Clay and Mr. Samuel Charles Clay, at Temple Mill Lane, Stratford, as artificial manure manufacturers, bone crushers, &c., under the style or firm of Clay & Son, has been dissolved as from the thirtieth day of November, 1896, by mutual consent. All debts from or due to the late firm will be discharged or received by Mr. Samuel Charles Clay, who for the future will carry on the business on his own account without alteration in the title.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," *8, Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Couplet (*Loveleia*).—We find you have not given the couplet quite correctly, as the second line should read, "Makes a barn fat and findy." From this it may be inferred that a cold and windy May will bring a full harvest. Whether this is borne out over a long series of years can only be ascertained by examination of the meteorological records, and the agricultural returns. We cannot inform you as to the origin of the saying, with which we were not previously to your letter familiar.

Colouring Gros Colman Grapes (*Cross*).—The Grapes will not colour so well without any heat in the pipes as with slight warmth in them, causing a gentle movement of the atmosphere, with sufficient warmth, to keep moisture from being deposited on the berries, and that, moreover, may save them from cracking and fungoid attacks. At night a temperature of 60° to 65° is necessary, and 70° to 75° by day, with the usual rise of 10° to 15° from sun heat. Air is a most important factor, with comparative coolness at night, especially when the Vines are heavily cropped. Sound health tells most, with judicious feeding, and too much stress cannot be laid on keeping the Vines free from red spider and thrips.

Cow and Horse Manure for Cucumbers (*C.*).—Horse manure is what is termed hot, cow manure cool, hence some cultivators prefer the former for strong and the latter for light soils. We prefer both together in farmyard manure, and in mixture about equal. There is little difference as regards "clubbing," but the cow manure containing more lime and less nitrogen is considered the least liable to favour eelworm in the soil. By mixing the two there is a better blend. We should mix the manure with the loam in the spring, having it in a thoroughly decayed state, and stack the loam with about 2½ per cent. of best freshly burned chalk lime and a sprinkling of kainit along with it, using about 7 lbs. per cubic yard.

Orange Tree Infested with Scale (*T. C. S.*).—The plant is infested with the scale insect (Lecanium hesperidium), and the sticky matter is its filth, which attracts ants. One of the best means of destroying the scale is to wash the tree with a solution formed as follows:—Dissolve 6 ozs. of softsoap in a quart of water by boiling, remove from the fire heat, and at once add a wineglassful of petroleum. Stir briskly with a switch or egg-whipper till thoroughly amalgamated, and place in a bottle or bottles. When required for use, shake well and add half a pint to half a gallon of water, and with that solution, using hot water, sponge the plant everywhere, when the solution is cooled to 100°. After sponging syringe with clear tepid water. The plant will require such treatment occasionally, as it is scarcely possible to grow Oranges without scale.

Diseased Outdoor Grapes (*Griffin*).—The Grapes sent for examination are severely affected by the so-called Vine mildew, an epiphytic fungus, named Oïdium Tuckeri, very common in dry seasons on Ranunculus acris and R. repens, also second crop Clover in late summer. The active stage of the parasite succumbs readily to sulphur. The first application should be made ten or twelve days before the flowers open, the second when in full bloom, and a third a fortnight or three weeks later. If the disease does not seem to be entirely subdued, another dressing may be applied about a fortnight after the third application. As regards the disease spreading to Vines near it, it is only a question of spores and moisture on the foliage, fruit, or shoots. The diseased Vine will furnish the spores. Neither sulphur nor anything else can repair seriously affected berries such as yours, but it may prevent the distribution of spores, especially if the sulphur is used when the sun shines powerfully on the Vine. By no means destroy the Vine. The procedure advised is founded on successful practice, and we have seen equally good results follow the timely application of anti-blight in the case of Vines which were for years white as millers, but now free from any speck of mildew.

Ismene calanthinum not Flowering (*T. C. S.*). — This Hymenocallis is not generally a free bloomer until it becomes large, and then requires to be kept dry during the resting period, or in winter. It is a warm greenhouse or cool stove species, requiring abundance of water during growth, but not making the soil sodden. The chief thing is to secure a good growth, and then mature it. Strong turfy loam is the most suitable soil, which must be well drained, and a rather liberal amount of pot room given. The bulbs should be buried just below the surface of the soil. Afford all the light practicable.

Colutea arborescens (*Inquirer*).—The shrub which you have seen in Battersea Park, "with leaves very much like an Acacia, yellow flowers something after the wild Broom, and pods like bladders" (a very good description) is no doubt the one above named, and, as you assume, belongs to the Nat. Ord. *Leguminosæ;* Tribe, *Galegeæ*. It is commonly called the Bladder Senna, in reference to the character of the pods, and because it is said that Senna (Cassia lanceolata) has been adulterated with its leaves. It is a native of Southern Europe, and is said to grow on the slopes of Mount Vesuvius, where no other plant exists. It is evidently a first-rate town shrub, at least in the South of England, for we know several examples of it growing and flowering freely in a small patch of a garden, enclosed on all sides by lofty buildings in the densely populated and smoke-enveloped "East End" of London.

Exhibiting Flowers (*Hamilton*). — In all questions of doubt relating to exhibiting flowers, or anything else, we have often stated that schedules should be sent with inquiries in order that the whole question and conditions may be understood. You say in your letter, "Of course there are the eight varieties, and they would be exhibited with the seedlings." This would no doubt be clear enough with the schedule before us, but it is not in the least elucidatory as it stands. We should regard your seedlings as half-hardy annuals, having regard to their origin; but if the Judges should rule otherwise, and their "decision is to be final," we suspect they would be the masters in this particular case. As to names, if the seedlings are distinct from all others, and, as you say, "splendid," you are at liberty to give them what names you like, which have not previously been given to other varieties of the genus to which the plants belong. If you like to send samples of the flowers we will tell you what we think about them. All letters and samples intended for the Editor should be sent to the address at the head of this column, not to Fleet Street.

Eucharis amazonica Infested with Mites (*Eucharis*).—It is generally advisable, when the plants become infested with this pest, to turn them out and cleanse the bulbs by means of some approved insecticide, there being few better than hot water, as hot as it can be borne by the hand for a minute (about 145°), letting the bulbs remain in it that time, rinsing or moving up and down so as to get the water into the scales or outer coating of the bulbs. They can then be potted in soil which has been scalded previously, so as to allow for draining and getting into good condition for potting. The plants should have bottom heat so as to accelerate root action, and get them soon re-established. This answers for a time, but in mite districts it seems to get on the plants again, when occasional applications of Clibran's Eucharis mite killer will keep it down, carefully following the instructions. You may use soluble phenyle, one part to ninety-six parts soft water, or 1 gill (¼ pint) to 3 gallons of water. Both may make the plants rather queer for a short time, but they recover, the substances then acting as manure.

Asters Dying (*A. W.*).—The plants are infested by a fungus in the stem (Botrytis cinerea var. sclerotiophila). Infection has probably been induced by an excessive use of enriching material, such as manure or leaf mould. It is a sort of "sickness," and by some considered due to a minute white worm, about an eighth of an inch long, which attacks the roots; there are some on your plants, and so there are on many other kinds of plants, especially Primulas, that die from the root upward both outdoors and under glass. It may be found in leaf mould and other decaying substances, and at most is semi-parasitic. It usually yields to dressings of basic slag phosphate, 14 lbs. per rod, and kainit, 7 lbs. per rod, applied in the autumn and dug in. The rains of winter will wash away the chlorine and leave the phosphoric acid, lime, potash, and magnesia in the soil. In the spring a dressing of freshly burned chalk lime makes assurance doubly sure, using ½ cwt. per rod, applying in dry weather, say in March, and pointing in with a fork, taking small spits so as to secure an even mixture. Manure can be given later, if necessary, always thoroughly decayed.

Caterpillar Found amongst Weeds (*W. Webb*).—The very fine specimen you have sent is the larva or caterpillar of the death's-head moth (Acherontia atropos, *Linn*). The caterpillar measures about 4 inches in length, thick, fleshy, with three pairs of feet. The fore legs are brown or black, head horny, and furnished with strong jaws. The colour of the caterpillar is greenish yellow, speckled with black on the back, with seven slanting stripes of lilac on each side, meeting along the back, and the lower ends pointing forwards white or bordered by a white line. The caterpillar turns to a lurid yellowish or reddish tint when about to change, then goes down into the ground, there throws off its skin, and turns to a large dark chestnut-coloured pupa with a tail, and though it lies in the ground all the winter has power of movement by means of the short tail and rings above it, always moving when handled, as if feeling the warmth of the fingers. The moth emerges from the pupa in the spring or early summer, and has a spread of wings of 4 to 6 inches, according to the size of the caterpillar in the preceding year. Fore wings rich brown, yellowish or rusty tinted, black lines waved and zig-zagged, with an ochre-coloured spot in the middle, and sprinkled with white spots. Hind wings bright orange, with two brown or black bands outermost broadest. Head black, with two horns (antennæ) rather stout and curved at the tips, and a curved proboscis for sucking the nectar of flowers, such as white Jasmine, and the moth is said to enter the hives of bees for the honey. The eggs are laid in hedges or amongst rubbish, and the caterpillars spread out for feeding, sometimes being found in Potato fields.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slight damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. M. C.*).—1, Gypsophila paniculata; 2, Montbretia Pottsi; 3, Bambusa Fortunei. (*T. J. H.*).—1, Adiantum gracillimum; 2, Nephrolepis devallioides; 3, Davallia canariensis; 4, Adiantum grandiceps; 5, A. trapeziforme; 6, A. cuneatum. (*E. C.*).—1, Abelia rupestris; 2, Escallonia rubra; 3, Centranthus ruber. (*P. P.*).—Houlettia Brocklehurstiana. (*W., Reading*).—Through being in the post over Sunday the flowers were shrivelled beyond recognition.

THE STACKYARD.

There is to the uninstructed eye little difference between one stack and another, and to speak of stackyard scenery would, and will perhaps, provoke a smile; but the great variety of stacks that

may be seen in different parts—good, bad, and indifferent, large and small—are to the intelligent observer a very interesting study. Who can deny that a group of well-made stacks (or more particularly the round ones that in Yorkshire are called pikes) crowning the hill-top or peeping from behind the clump of Scotch Firs, does not add very materially to the picturesqueness of any landscape?

But stacks are made for use, not for ornament. Certainly; but it would be difficult, or impossible even, to make a handsome stack without at the same time making a good one. Of course the first object in building the stack is the safe preservation of the corn of which it is made, therefore the roof is the most important part; but the foundation must be well looked after. It is a good plan to build the stacks every year on the same places, and to have those places raised slightly higher than the rest of the stackyard.

We do not often vary the size of our stacks—at any rate, as regards length, and if the steddle or foundation slope gently from the middle the stack may be made smaller or narrower, as occasion requires. A raised steddle being used, not so much straw will be necessary as if the stackyard were all on a dead level; but in any case, dry straw or other similar material quite a foot thick (as thrown down) must be used to put the new grain upon. It is very annoying to find two courses of sheaves at the bottom of the stack mouldy and rotten, either from having been stacked in a low, badly drained place or from having been placed upon wet straw. Having a good dry foundation sloping from the middle we must take every care not only to preserve this slope, but to increase it. The first sheaves go into the middle, and the essential point in making a good stack is to have the outside sheaves sloping from the centre at such an angle that they are in danger of slipping off until an inner course has been placed upon them. If a stack be built on this principle, and carried out gently so that the eave overhangs the base by a foot all round, there is only the roof left to consider.

Rough timber, tree tops, and rough Thorns are often used to make stack bottoms, and very useful they are if there are no rats about, otherwise they are a great encouragement to the rat to make his abode in them; such a home, with plenty of food above, is just what Mr. Rat dearly loves. We should prefer a more solid bottom, such as is provided by broken stone or earth.

Now we come to the most important part of all, the roof. Having carried our stack to the square, that is the point from which we intend the roof to spring, we must begin to fill in, or in other words to increase the proportion of sheaves towards the middle so as to accentuate the outward slope. A stack when filled in ready for roofing presents rather the appearance of already possessing a flat roof, but much more is required. We proceed by laying an outside course 9 inches within the outer edge with other binding courses upon it and each other; the next outer course will be brought in again, and so on until the sheaves reach across the top, then a few sheaves may be laid lengthwise, and straw on the top to keep all snug. A good roof should have something of a shoulder, that is the pitch should not be uniform as in the roof of a building, but greater near the eaves, as it is that part which is the most likely to let in rain, if there is not sufficient slope.

The shape of the stack is either a matter of taste, or, as in some districts, one that leaves little or no choice to the farmer if he is to save his crops. In a fine harvest, when the grain is in the driest of conditions, we think there is nothing to beat the Yorkshire pike. We have seen them 10 yards in diameter at the base, and 12 yards at the square. A stack like that, proportionately high, will contain from 100 to 120 qrs. of Wheat, and very little of it is exposed to the birds and the weather; but with unfavourable conditions of weather, which is the annual occurrence in some northern localities, it would be almost impossible to secure the crops in such order as to make it safe to put them into such huge heaps—the stacks must be smaller or narrower. Barley and Oats especially, unless in the finest condition, must not be stacked so that any portion is 7 feet or more from the outside.

This, to stick to the round shape, would mean a large number of small stacks, and heavy expense in thatching. We, therefore, whilst using pikes for the Wheat in most years, find it safest to put the Barley and Oats into long narrow stacks about 4 yards wide and 12 long. These we build end on to each other in close contiguity, two, three, or four in a row. They can be all thatched as one roof, and thrashed one at a time if required. The extreme ends are made round, and the roofs the same, so that there is no gable end. A gable end is difficult to make waterproof without sacrificing appearances.

We are quite certain that for big heaps there is no shape to equal the pike, and they are quite as easy to build if people will but have a try.

WORK ON THE HOME FARM.

Work amongst the corn early and late occupies each and every day. We have had a nice rain, which has greatly benefited the root crops and pastures without materially injuring the grain; probably even the ripe Barley would be the better for it. Fortunately the rain fell on Sunday, so the harvest was not hindered.

Binders are making splendid work, and are almost universal. Shoals of men in vain seeking work are passing along the roads, and would, no donbt, be easy to treat with if anyone wanted them.

Grain crops on the whole are cutting up well, if anything better than our anticipations; the drought had given them an appearance of lightness which was more superficial than real. Barleys are a good colour, but will be very thin and steely. The kindest samples will come from the low-lying lands.

Most of the corn is cut about us but not much led. It is well to be careful and give the crops plenty of field room this season. They have finished off rapidly, and in many cases were much greener than they looked. The ears appeared ripe and the straw yellow, but the knots were very green when the corn was cut, and until the nature in the straw has had time to dry up it is dangerous to put it into a stack. There is generally more heated corn in a fine harvest than in a wet one, because farmers will not give the straw time to get properly made.

We are inclined to leave our Barley out a little longer on the chance of more rain falling. A good rain on the stooks would do the grain much more good than harm. One rain would not affect the colour much, and it would add much to its malting qualities.

Some people are anxious to be moving the Wheat stubbles as soon as the corn has been cleared away. This year they are so hard that even the spring-tooth cultivator will hardly face them. However, lamb meat is so scarce that perhaps few will attempt to work them, at any rate until the sheep have had a few days' run upon them.

Milch cows have fallen off much in the milk, and fat stock lately have hardly held their own.

SOUTH-EASTERN AGRICULTURAL COLLEGE.

THE South-Eastern Agricultural College at Wye, established and maintained by the County Councils of Kent and Surrey, was visited last week by a large gathering of representatives of the agricultural community in both counties, on the occasion of a distribution of prizes and diplomas by Earl Stanhope, the Lord Lieutenant of Kent. The Principal, Mr. A. D. Hall, referred to the highly encouraging examination results thus early in the career of the college. The Royal Agricultural Society had passed two men, awarding the gold medal and life membership to Mr. A. Holm, of Betchworth, Surrey. The Surveyors' Institution had passed all candidates presented for the first degree. Similar successes had attended the candidates for the Cambridge University Diploma of Agriculture, and for the British Dairy Farmers' Association.

REMARKS.

8th.—Heavy rain from 9.30 A.M. to 1 P.M., and showers after, but much bright sun in afternoon.

9th.—Overcast early; occasional sunshine in morning; bright afternoon.

10th.—Bright sunshine all day; overcast evening.

11th.—Generally overcast, with spots of rain, till 5 P.M.; bright evening.

12th.—Frequently cloudy in morning, but brilliant early and after 2 P.M.

13th.—Overcast with frequent spots of rain early; occasional faint sunshine after 11 A.M.; showers in evening, and rain at 11 P.M.

14th.—Alternate cloud and sunshine.

Another warm week, but not so much above the average as the previous ones.—G. J. SYMONS.

Journal of Horticulture.

THURSDAY, AUGUST 26, 1897.

THE JOURNAL OF HORTICULTURE *can be obtained from the Office, 171, Fleet Street, London, post free for a Quarter, 3s. 9d. Editorial communications must be addressed to 8, Rose Hill Road, Wandsworth*

THE DECADENCE OF WALL-FRUIT CULTURE.

THIS is one side of a story of which, as with most, there are two. On the bright side—and it is but fair to turn to it for a moment, although it needs but little comment—we may see those intelligent expositions of gardening under which this subject receives that consideration it deserves, deriving from it corresponding good results. Yet I venture to assert, from personal observation, that for every good example to be found there are two the reverse—one showing sheer neglect, the other decided mediocrity: hence the conclusion is arrived at that in this matter at least we have fallen, and are still falling, away from the excellent practice of our forefathers. Corroborative evidence is afforded by more than one lament from high places over the disappearance of the luscious open-air Peach of boyhood days; and not that alone, for those magnificent dessert Plums, the pride of a past generation, are often, too, conspicuous by their absence.

The causes which have led to this are not far to seek. So far as Peaches are concerned, where the question of open-air culture crops up the matter is dismissed by saddling the deficiency upon that scapegoat, the weather. Indeed, the decadence of this phase of cultivation with Peaches is not rarely adduced as a proof of sufficient climatic change to have brought about the result. Granted what is proved by the ethics of geological and geographical science to be the case, such changes in the forces of Nature are spread over too large, too vast intervals of time to affect the question to any appreciable extent, and the impotency of any attempt to compute such changes from data as afforded by a few generations may be admitted. Doubtless many will say that with the great facilities now at hand in the way of glass protection, Peach growing in the open is practically unnecessary. That is another matter; but with those who have some lingering regard for the past, and attach any importance to its bearing on the present, then, given the same care and attention to the tree on the wall as is afforded to it under glass protection, excellent results are still to be obtained.

One notable instance *apropos* of the above may serve to illustrate the case. In a garden of moderate dimensions, where all things were well under control, were grown year after year, probably are still, some of the finest Peaches it is possible to see. The first time the trees came under notice the care and skilful treatment bestowed upon them was very evident. This was at that critical season, early spring, when the trees would have been tempted in blooming had not measures been taken to retard them as long as possible, to effect which they had been disengaged from the wall (a good red brick wall with a S.W. aspect), and the strong brown wood bristling with latent buds was secured in loose bundles to stakes firmly fixed as far from the wall, and consequent excitement, as possible. A little questioning upon the matter showed that the zealous gardener was an enthusiast in this phase of culture, and elicited the whole routine of operations. This amounted to no more than high-class treatment of trees as generally displayed and ungrudgingly given under glass, but no less, be it understood, comprising periodical lifting, strict attention to the border, which was wholly devoted to them, the same care with watering, all details pertaining to cleanliness, thinly disposed wood, and a vigorous thinning of the fruit. Under these conditions history, as far as successful outdoor Peach production is concerned, is well able to repeat itself.

With the employment of our walls for fruit culture generally, apart from the benefits derived from glass protection in whatever shape or form, the subject is of sufficient importance to claim more attention than often obtains and which is evidenced by the desultory, half-hearted way in which many of the trees are cared (?) for. It would, perhaps, be a bold thing to say that gardeners of to-day are warped to their glass houses, although, here and there, instances may be noted which tend to that conclusion. However that may be, the bedding craze which has had so many sins of omission to answer for generally, may bear much of the burden of this shortcoming in particular. Happily the extreme has long since been touched, and a healthy reaction has set in, to the end, probably, that our garden walls will no longer bear the evidence of neglect as seen in starved trees carrying their breastwood too late in the autumn, and receiving but little more attention than one gives to a hedge with the object of having it tidy, and that deferred to include all in the one operation. It is reasonable to suppose that we shall never return to those hard and fast lines as practised by our ancestors, of which the decaying monuments still bear witness of an untiring patience to attain the perfection of geometrical training; but rational freedom, not unbounded license, may give us lines of beauty more in harmony with the practical spirit of the age.

One would like to see the hands of our young gardeners afforded a little recreative play in this direction, for all have not in the ordinary routine of their work opportunities for it. As a suggestion to those whose crippled resources in coping with a season's work leave an opening for improving this phase of fruit culture, all-round good might result if each lad in the bothy was given the care of one or two trees, Peaches, Apricots, Plums, or Pears, in his leisure — after the orthodox working hours. This opinion and theirs are, doubtless, widely divergent now upon such matters, but later in life they will meet on common ground, and that is sufficient. As a young man nothing afforded me greater pleasure than the taking in hand of some neglected Plum trees on a wall, and the pinching, pruning, nailing, watering, washing and thinning gave such marvellous results in two short seasons that a lifetime will never obliterate the satisfaction derived from it.

There are essentially a few characteristic features prominent in the ordering of a well-kept garden, and these will strike the eye of an interested observer. They are, in fact, the keynote to a harmony of which all other cultural details are, without disparaging their importance, but minor notes. We enter some fine old garden, historical mayhap so far as gardening is concerned, and from the walks, which do so much to make or mar an agreeable impression, a searchlight of criticism sweeps the garden walls. Sentiment in a measure guides us to the surface of things, but all the profit and pleasure derived from sound gardening is speedily analysed and assimilated in one critical glance.

There is no square foot of a garden wall but what should contribute that quota to the credit side an intelligent workman is able to extract from it, and to me a good garden surrounded by a neglected wall is like a fine picture in a shabby frame.—INVICTA.

CHEMISTRY IN THE GARDEN.

(*Continued from page* 415, *last volume.*)

Relation of Soil to Water.—One of the most important physical properties of soils is their power of absorbing and retaining moisture. Gardeners who have been engaged in different part of the country know only too well how plants growing on some soils become wilted, stunted in growth, and assume a sickly yellow colour during a drought; while under the same conditions on other soils they appear quite fresh and green. The soils first referred to have not the power to absorb and retain moisture for any length of time, while the latter can, and are therefore able to supply crops with water for a longer or shorter period, which will naturally vary according to the nature of the soil. The absorption and retention of water by soils is greatly influenced by several important circumstances, the following being those of most importance, and consequently the only ones we need consider:—(1) The amount of clay, sand, carbonate of lime, and humus a soil contains; (2) the degree of fineness of the soil particles; and (3) the depth of the soil and nature of the subsoil.

In considering the influence which sand, clay, and humus exert upon the absorptive and retentive power of soils for water, we shall do well to make use of a few extracts from a table of experiments carried out by Schübler. He first of all obtained samples of different kinds of soil, and after drying them, saturated equal weights of each with water. The samples were then allowed to drain until all the superfluous water had passed away, when each lot of soil was again weighed, the difference in weight between the dried and wet soil being the amount of water each lot was capable of absorbing. Below are a few of the results thus obtained:

100 lbs. of sand	..	..	absorbed	25	lbs. of water.
100 ,, sandy clay	..		,,	40	,, ,,
100 ,, strong clay	..		,,	50	,, ,,
100 ,, garden soil	..		,,	89	,, ,,
100 ,, humus	..	..	,,	190	,, ,,

The above table shows us that sand is not able to absorb much water, but by the addition of a certain amount of clay greater absorptive power is given to a sandy soil. Humus, or decaying vegetable matter, is capable of absorbing a large amount of moisture, and it is owing to the presence of this substance in the garden soil that makes the latter able to absorb and retain so much moisture.

A good illustration of this is shown by some of the Rothamstead experiments. A sample of soil was taken from an unmanured plot, and on being saturated with water was found to be capable of absorbing 32·4 of water per 100 of dry soil. The same amount of a similar soil, which had received a dressing of 14 tons of farmyard per acre per annum for twenty-six years, was able to absorb 65·8 of water per 100 of soil. Stiff clays, although capable of absorbing a large amount of water when it is poured upon them, are not the soils which absorb the most moisture from the atmosphere, consequently in wet weather clays are very wet, but during a drought the surface dries quickly and becomes very hard, and large deep cracks radiate in all directions. Humus will improve the condition of such soils, making them mellow and easier to work. Carbonate of lime, if applied in a fine condition, will also improve the retentive power of soil, especially those of a sandy nature.

The degree of fineness of the soil particles has considerable influence on the retention of the soil water, for up to a certain point the finer the particles the more water will be absorbed. When the soil is saturated after heavy rains all the interstices will be filled with water, but if the soil be well drained all the water between the particles will drain away. If we pick up a stone which is lying on moist ground we find the under surface covered with a film of moisture. Every particle of soil is surrounded by a film of water which adheres to its outer surface, so it must naturally follow that the more particles of soil there are the more water will the soil retain.

One hundred pounds of a rather coarse chalky soil, when saturated, was found to be able to retain 29 lbs. of water, but when the same weight of soil was pulverised its retentive power was increased so much that it was found capable of holding 85 lbs. of water. Professor Wrightson has shown that while 100 lbs. of a very coarse sand could only retain 7·0 lbs. of water, the same weight of very fine sand would hold 44·6 lbs. We must also remember that chalk and humus are porous substances, therefore they can retain water in the same way as it is taken up and held by a sponge.

The depth of the soil and the nature of the subsoil are the next

points for our consideration. As many of us are aware, a shallow soil with a gravel subsoil is about the worst land it is possible to have, for such a soil allows the rain to pass through it freely, and there is no means of holding it at a depth which is of any value to plants. A light soil resting upon a clayey subsoil is a good combination, although the latter may require to be trenched and drained. The clay would retain plenty of moisture, which would be brought within the reach of the roots of plants by capillary attraction. It is very beneficial to plants to break up the subsoil, even if it is not suitable to bring or mix it with the surface soil. A deep soil and subsoil allows the roots of plants greater freedom and more root room, and crops are not so liable to feel the effect of drought, because the soil by its greater bulk is capable of retaining a large quantity of water.—W. Dyke.

(To be continued.)

HOME-MADE WINES.

Currant Wine.

To make 18 gallons of this wine take 28 gallons of fruit picked from the stalks and perfectly ripe. Let it be thoroughly bruised and put into the fermenting tub. Strain out a portion of the juice and test its gravity by the saccharometer. Allow the mass to remain until it is found that the gravity of the juice begins to decrease. Then let the juice be strained off and the skins of the fruit well pressed, and when pressed throw the skins into a tub and pour 2 gallons of cold water over them to extract the remaining good they may contain. Press them again, and what juice is obtained mix it with the other, which must be returned to the cask without a head.

The pure juice is now to be tested by the saccharometer, and if it stand at any degree above 30° it is to be reduced to that point by the addition of cold soft water. From the specific gravity of 30 it must now be raised to that of 120 by the addition of sugar, which will probably take about 2½ lbs. to every gallon of liquor. When the sugar has been dissolved fermentation will commence, and now a pound of powdered argol is to be added to the must.

Every day the must is to be tested by the saccharometer till it is found to have decreased to from 80 to 90. When it is at 80 it is to be drawn off from the tub into a cask, which has been previously well washed with boiling water, and while it is yet warm, as this tends to keep up the vinous fermentation in the cask. The bung-hole must be left open to enable the wine to throw off its yeast and impurities, and as it shrinks in the cask keep filling it up to the bunghole with that which has been reserved in the 2-gallon cask. Fermentation must be encouraged in every way until the gravity has been reduced to 30, when the cask may be bunged up. The wine ought to remain in cask till November twelve months before it is bottled.

Black Currant Wine.

The same directions for making Currant wine, which have already been described, will apply to making ordinary Black Currant wine; but when a very superior quality is required the following process must be adopted:—To two parts of fruit take one part of water—that is, to every 2 gallons of fruit take 1 gallon of water. Crush the fruit gently and put in a tub, then add the water. Stir them together, and then put them into a copper and boil them for ten minutes, after which draw off and strain. The berries are now to be pressed, and 2 additional gallons of water poured on them, and this also is to be strained from them and added to the original quantity.

When the liquor is cooled down to a temperature of 90°, which must be ascertained by the thermometer, it is to be tested by the saccharometer and enough lump sugar added to raise the gravity of the must to 125. One pound of powdered argol is now to be added to every 20 gallons of must, and when the temperature falls to 85° put in a pint of good fresh brewers' yeast. Fermentation is now to be encouraged till the specific gravity is reduced to 50, when the wine is to be put into well-cleansed casks, and the longer it is kept in the wood before bottling the better it will be.

Ripe Gooseberry Wine.

Take 10 gallons of ripe Gooseberries, bruise them and throw them into a tub, where they are to remain for twenty-four hours, and be afterwards pressed in a haircloth or canvas bag. Return the mass to the tub and pour 5 gallons of moderately warm water over it, mixing the whole well together. After remaining for about twelve hours take it out and press it again through a haireloth or canvas bag, the liquor from this second pressing being added to the original. Now test the gravity of the liquor by the saccharometer, and raise it by the addition of sugar to 120. As soon as fermentation begins add for each gallon of the liquor 1 oz. of powdered argol. When fermentation has nearly ceased draw it off into a cask, which must be kept constantly filled to the bung-hole from the reserve which has been kept for the purpose. The liquor is to be frequently tested by the saccharometer, and when it has been reduced to 25° or 30° it is to be bunged up and allowed to remain for twelve months, when it may be fined and bottled, or left in the cask to mature.

Cherry Wine.

(1). The best Cherries for this purpose are the Black Heart, Black Corone, Mazzards, Merries, or Geans.

Remove the stalks, then bruise the fruit thoroughly without crushing the stones, strain out the juice, and to every gallon of juice add a gallon of water. Put half the quantity of water already used over the fruit which has been strained. Stir all well up together, leave them for twenty-four hours, and then press the liquor from the fruit, and add it to the former quantity.

Test the liquor by the saccharometer, and add sufficient sugar to raise the gravity to 120. To every gallon of the juice add 1 oz. of powdered argol. Draw the liquor off into a cask filled to the bung; and as the bulk wastes by fermentation keep the cask filled from a reserve which has been kept. When the hissing has ceased, and the gravity has been reduced to 30, bung up the cask, and allow it to remain till November twelve months before bottling.

(2). This second recipe is for a wine of somewhat different character, and of very superior quality to the former, and may be preferred for the noyeau flavour supplied by the crushed kernels and the addition of the Raspberries.

To make a 9-gallon cask of wine will require 190 lbs. of fruit, allowing for the waste in the fermentation.

The Cherries to be used are the same as those already mentioned in the first recipe. They must be ripe and sound. After bruising them, remove the stones and allow the pulp to remain in the fermenting tub for twenty-four or twenty-six hours, so that the skin may during that time yield up all its colouring matter; then strain the whole through a cloth. Test the juice by the saccharometer, and add as much sugar as will raise its density to 120°. Put into a cask, reserving some to fill up what is lost by the fermentation. This will be at the rate of about 3 quarts per 5 gallons. Add 1 oz. of powdered argol to the gallon. When the fermentation, which will last fifteen or eighteen days, has ceased, bruise the stones, add them to the wine, and bung up the cask. Let it remain in the cellar for three or four months, and bottle it off. It will add to the flavour of the wine if a few pounds of Raspberry juice is added before fermentation has ceased.

Raspberry Wine.

To every gallon of ripe Raspberries picked from the stalks put half a gallon of water. Stir them well up together, and thoroughly bruise the fruit. Strain off the liquor, and squeeze all the juice from the fruit, adding it to the liquor which was previously drawn off. Test the weight of the liquor by the saccharometer, and make it up to 120 by the addition of sugar. To every gallon of liquor put 1 oz. of argol powdered and dissolved in a portion of the liquor. Put it all into a cask, and allow it to ferment till the gravity is reduced to 30, and keeping the cask full as the liquor shrinks by the fermentation. When fermentation is complete bung up the cask, and at the end of three months rack it either into a clean cask, or return it to the old one after it has been thoroughly rinsed and cleaned. In six months more it may be fined and then bottled.

Orange Wine.

Boil 20 gallons of water, and when nearly cold pour it upon 60 lbs. of raisins cut or chopped small. Let them work together in the fermenting tub for ten days, stirring them twice every day.

In the meantime procure 120 sweet Oranges, and pare them as thin as possible, preserving the skins. Cut the Oranges in two and squeeze out the juice, putting it and the pulp into a tub or other vessel.

As soon as the raisins have remained the required time in the fermenting tub strain off the liquor and press the raisins, extracting all the juice. Measure the liquor, and if it has lost in quantity add as much water as is deficient to the refuse of the raisins, which stir up in it, and after pressing add the liquor to the original quantity. Heat a quantity of the liquor to 170° and pour it on the peels of the Oranges; and when cooled down to 90° press them and mix with the raisin liquor, which must now be poured on the juice and pulps of the Oranges, there to remain for one night. Stir it up next day and strain it.

Now test the gravity by the saccharometer, and it will probably be about 45. Make it up to 120 with the addition of sugar, at the same time add three-quarters of a pound of argol, which must be previously dissolved in 2 quarts of the hot liquor. Leave it till it shows 90 gravity by the saccharometer, when it is to be put into an 18-gallon cask, reserving 2 quarts; in one of which dissolve half an ounce of cochineal previously well pounded, and in the other 1 oz. of isinglass, and when they are cold add them to the cask, stirring them well up together. Leave the barrel without bunging it for a fortnight, and then bung it up.

(To be continued.)

SHREWSBURY—ROYAL COMMEMORATIVE SHOW.

AUGUST 18TH AND 19TH.

NEITHER storms that blow down tents during the preparation of the Show, nor drenching rain that falls continually soon after the opening, seem to do little more than cause loss to the exhibitors who suffer, and extreme discomfort to thousands of visitors. The Society itself appears to flourish under all circumstances, and its triumphs only seem the greater in surmounting natural obstacles. The downpour towards the evening of the first day stopped the progress of everything outside the tents, and prevented the evening fireworks, but did not stop the visitors, and hence the marvellous result of a larger "gate" than on any first day over the whole long series.

Then came the second day, which was fortunately fine, and nearly a hundred trains brought in their living freights in scores of thousands, making this great commemorative exhibition, and appropriately so, a record one of attendance and financial results. We have not the exact figures, but suspect the income from all sources during this Royal Jubilee year will be well on the right side of £4000.

The meeting in the famous Quarry Grounds must be reported as a success in every way. The visit of the Royal Horticultural Society was very popular; the presentation to the indefatigable Secretaries met with unanimous approval; the splendid prizes and medals generously provided by the Society, and contributed from various sources, imparted interest and strength, in all cases being well and keenly contested for.

One of these medals demands a special line as being unique. Designed by the Countess Feodore Gleichen for Lord Kenyon, the President of the Shropshire Society, for presentation to the two gardeners taking the largest amount in prizes—one in the open, the other in the county classes, the die then to be destroyed. Thus these Victorian medals will remain the only two existing, and to be cherished the more by their recipients, Mr. James McIndoe, The Gardens, Hutton Hall, Guisborough; and Mr. C. Roberts, gardener to C. H. Wright, Esq., Halston, Whittington, Salop. The medals are of silver, antique in design, 4½ inches in diameter, very massive, and oxidised. We are indebted to practical gardeners for the following report of the chief exhibits in the different sections at this great Show. A large number of local classes, in which both amateurs and gardeners acquitted themselves well, could not be particularised, nor could the cottagers' products, which were of such remarkable excellence, and most creditable to the workers of the district.

GROUPS AND PLANTS.

Despite the disaster which occurred to the large marquee containing the chief miscellaneous groups of plants belonging to Mr. Cypher, as adverted to in our last issue, the redoubtable exhibitor secured the first honours in the two principal classes. His collection of twenty stove and greenhouse plants, which, to the casual observer, appeared to have suffered comparatively little, were in fact wrecked, the magnificent Cycas circinalis, which had not been exhibited since the last Shrewsbury Show, was ruined. Heaths of nearly twenty years' growth can never be themselves again, while Ixoras and others were smashed.

GROUPS.

Mr. Cypher's group of plants (fig. 27, page 197), in or out of bloom, arranged to produce the best effect, and occupying a space of 450 square feet, was indeed a splendid triumph of artistic plant association, and of which it may safely be said eclipsed either of his previous efforts. It was a replica, but on an extended scale, of his group exhibited at Wolverhampton in July last. There was, however, a greater profusion of Orchids and other suitable plants depending from the cork-bark covered alcove and arches. These, stretching over and between the tastefully disposed variegated Crotons and other foliage plants, formed the groundwork of the design, whilst such plants as Humeas, Palms, and the ever graceful Bamboo, Arundinaria falcata, served to form the highly effective background. In addition to the valuable first prize (£35) a silver-gilt Flora medal was bestowed upon Mr. Cypher for this splendid group.

Mr. Chas. T. Mee, Nottingham, was accorded the second honours (£27 10s.), with also a silver-gilt Flora medal, for a highly meritorious group. It contained a rich assortment of tall and finely coloured Crotons and other ornamental foliage plants, with Pitcher Plants (Nepenthes) and Orchids. The back of the group was centred with a massive cork bark arrangement, from which sprang tall plants of Palms, Bamboos, and other excellent plants, forming altogether a most effective design. Mr. W. Finch, Coventry, was awarded the third prize (£20) for also a telling arrangement.

In the class for a group of ornamental foliage plants, occupying a space of 250 square feet, Mr. C. H. Wright, Oswestry, won the premier position with a most effective arrangement of Crotons, Dracænas, Palms, Bamboos, and other appropriate plants; Mr. Cypher being a close second with a somewhat similar composition. The third prize was well won by Mr. J. McIntyre, gardener to Mrs. Gurney Pease, Woodside, Darlington; an extra prize being worthily adjudged to Mr. S. Bremmell, gardener to H. H. Hayhurst, Esq., Wellington. The groups last mentioned afforded a pleasing relief to the miscellaneous ones, and proved excellent examples of decoration, in which ornamental foliage plants alone so readily lend themselves.

SPECIMEN PLANTS.

Coming to the class for twenty stove and greenhouse specimen plants, Mr. Cypher was found occupying his old position—first. The following is a list of the collection:—Statice profusa (a fine large specimen), Allamandas nobilis and Hendersoni, Dipladenia Brearleyana, Clerodendron Balfourianum, Bougainvillea glabra. Ixoras salicifolia, Williamsi and Duffi, Erica obbata, E. Austiniana, and E. Eweriana, whilst a richly coloured specimen of Bougainvillea Cypheri completed the flowering section. This last specimen also gained a gold medal as the most meritorious flowering or foliage plant in the show. The foliage section comprised a grand specimen of Croton Thompsoni, with fine and large leaves, presenting a mass of yellow; C. Johannis, C. Baron James Rothschild, C. angustifolium, Latania borbonica, Kentia australis, and K. Fosteriana. Mr. W. Finch, who was the only other exhibitor, was awarded the second prize for also a good collection, though hardly attaining to some of his previous efforts. He was no doubt prejudiced by the accident of the previous day, for some of his plants were crushed by the falling marquee.

For six plants in flower, Mr. Cypher was deservedly awarded the first prize. The collection included fresh and neat medium-sized specimens of Phœnocoma prolifera Barnesi, Clerodendron Balfourianum, a profusely bloomed Rondeletia brilliantissima, Statice intermedia (very good), Bougainvillea glabra, and Erica Austiniana. The second prize was won by Mr. W. Finch with very good specimens of Ixora Fraseri, Erica retorta major, Allamanda grandiflora, Statice profusa, and Allamanda Williamsi as his best, the third prize falling to Mr. T. Lambert, gardener to Lord Harlech.

For six stove and greenhouse plants, open to the county of Salop, Mr. T. Lambert, Mr. C. Bremmell, and Mr. J. Farrant (gardener to Mrs. Juson, Monkland, Shrewsbury), were awarded the prizes as in the order named, with fairly good examples. For a single specimen stove or greenhouse plant in flower, confined to Shropshire, the first prize was adjudged to Mr. T. Lambert for a very good and profusely flowered example of Dipladenia amabilis. Second prize to Mr. J. Farrant for a large specimen of Ixora Fraseri, and the third was taken by Mr. A. Jones, gardener to G. Burr, Esq., Shrewsbury, with a fair example of Bougainvillea glabra.

VARIOUS PLANTS.

In the class for six Dracænas there were four competitors, Mr. T. Lambert taking the lead with fair examples, including the varieties Shepherdi, amabilis, Baptisti, Sunset, and Reginæ; the second position being secured by Mr. S. Bremmell for very good, but unnamed plants; while Mr. C. J. Mee, Notts, was placed third, there being four exhibits.

Caladiums were very well represented, and for six specimens Mr. R. Hawley, gardener to Mrs. R. Darley, Adcote, was placed first; Mr. W. Leith, gardener to J. R. Greatorex, Esq., second, and Mr. J. Farrant occupied the third position. Coleuses were also well shown as richly coloured pyramids. The first prize was accorded to Mr. J. Carter, gardener to W. J. Scott, Esq., Besford House, Shrewsbury; the second to Mr. A. Myers, Shrewsbury, and the third prize to Mr. S. Bremmell.

Fuchsias were a pleasing feature, inasmuch as they were not closely trained. The first prize was taken by Mr. A. Myers for three large, well flowered, and fresh examples. The second fell to Mr. J. Carter, and the third prize to Mr. T. Hughes, Shrewsbury. Begonias (tuberous-rooted) were fairly well shown by Mr. E. Jones, Wellington, and Mr. R. Taylor respectively; as were Zonal Pelargoniums. Mr. A. Myers and Mr. W. Clift, gardener to R. Taylor, Esq., secured the prizes both for six double and six single flowered varieties in the order named. Gloxinias were not a strong class, though some well grown plants were staged, Mr. J. Parson Smith, Abbotswood, being placed in the first, and Mr. W. Dawes, gardener to A. E. W. Darby, Esq., in the second position for twelve plants. Exotic Ferns were exhibited with much credit by Mr. E. Jones, gardener to A. M. Barber, Esq., Wellington, and Mrs. M. Slaney, Sunnycroft, Wellington.

An interesting and very well represented class was that of twelve plants suitable for table decoration, grown in pots not exceeding 6 inches in diameter. First honours were well won by Mr. J. McIndoe, gardener to Sir J. W. Pease, Bart., Hutton Hall, Guisboro', with elegant and neat examples of Crotons, Palms, and other plants usually employed for the purpose, the second prize falling to Mr. McIntyre, and the third to the gardener to the Hon. Mrs. E. Kenyon, Maesfew, Whitchurch.

For a collection of miscellaneous plants grown in pots not exceeding 5 inches in diameter, not less than twenty in bloom, the prizes were accorded to Mr. H. Jones, Mr. J. Carter, and Mr. J. Farrant respectively, for very good displays.

Orchids were sparsely represented, but a fairly good collection was shown from the gardens of Col. R. T. Lloyd, Aston Hall, Oswestry.

NON-COMPETITIVE EXHIBITS.

It was almost impossible to obtain particulars of these owing to the density of the crowd. Messrs. Richard Smith & Co., Worcester, were represented by a very fine collection of plants in variety, and for which a silver Flora medal was bestowed.

Messrs. James Veitch & Sons, Chelsea, made a magnificent display with numerous choice Caladiums, Nepenthes, and various other plants, besides bold masses of splendid Lilies of the Valley, well winning the gold Banksian medal of the Royal Horticultural Society. Awards of

merit were also granted to the same firm for Caladium Silver Queen and Dracæna Princess Charles of Denmark, both of them distinct and beautiful varieties.

The Royal Society's awards in this department of the Show were made as follows :—Mr. J. Cowan, of Garston, silver Banksian medal for group of Tea Roses, Lilies, and Orchids; Messrs. R. P. Ker & Sons, Liverpool, Royal Society's silver Flora medal for group of Crotons; Mr. H. H. France-Hayhurst, Overley, special commendation certificate for Rhododendron Princess Royal; Messrs. Veitch & Sons, London, gold Banksian medal for best representation of Victorian era group, also certificates of merit for Dracænas and Caladiums, as well as the Victorian award—a handsome dessert service; Messrs. R. Smith & Son, of Worcester, silver medal for group of plants; Mr. J. Cypher, gold medal for group and silver medal for stove and greenhouse plants; Mr. C. J. Mee, of Nottingham, silver Flora medal for group for effect; Mr. A. Myers, Shrewsbury, silver Banksian medal for Fuchsias.

The Shropshire Society's special awards in the large tent were :—Mr. J. Cowan, Garston, gold medal for groups of Orchids, Roses, and Lilies; Messrs. R. P. Ker & Sons, Liverpool, gold medal for Crotons; Messrs. R. Smith & Sons, Worcester, gold medal for collection of plants.

In the tent nearest to Quarry Place the Royal Societies' awards included the following:—Mr. W. J. Scott, Shrewsbury, special commendation certificate for Coleus; Mr. A. Myers, Shrewsbury, special certificate for Coleus, and the silver Banksian medal for Zonal Pelargoniums.

Another firm of local florists who were similarly honoured was Messrs. Jones & Sons. They had a most attractive stand of cut flowers of their own growing, and were presented with one of the Victorian awards for this exhibit. Messrs. Dicksons, Chester, made a grand display of flowers and plants, for which they received the silver-gilt Flora medal of the R.H.S. and the silver medal of the S.H.S.; and Messrs. Webb and Sons were awarded the silver medal of the S.H.S. for a grand collection of flowers, fruit, and vegetables. A like honour was bestowed upon Mr. Albert Myers, Shrewsbury, who showed a wonderfully fine lot of flowers. Messrs. Dobbie & Co., of Rothesay, exhibited a beautiful stand of Dahlias, for which they were awarded the Banksian medal of the R.H.S. and gold medal of the S.H.S.; Mr. B. R. Davies, of Yeovil, received the Flora medal of the R.H.S. and the gold medal of the S.H.S. for a fine lot of Begonias; Mr. J. Hudson (gardener to Mr. Leopold de Rothschild) was given the silver-gilt Flora medal of the R.H.S. and the gold medal of the S.H.S. for a collection of hardy Water Lilies; and Messrs. W. & J. Birkenhead the silver medal of the S.H.S. for a stand of Ferns. Mr. Campbell, High Blantyre, gained the silver Banksian medal for a collection of cut Carnations and Picotees; Messrs. Perkins a Flora medal for exhibits in classes 24, 25, and 31, and Messrs. Carter a gold medal for their fine stand at the entrance to the tent. Other exhibitors were Colonel R. T. Lloyd; Messrs. Eckford, Wem; R. W. Proctor & Son, Chesterfield; S. Mortimer, Farnham, Surrey; J. H. White, Worcester; James Backhouse & Son, York; W. F. Gunn, Olton; Jarman & Co., Chard, Somerset, &c.

In an extra tent Messrs. Pritchard & Sons, nurserymen, Shrewsbury, showed a fine collection of Potatoes, for which they received a Victorian award consisting of a handsome full dessert service of the value of £12 12s. The collection included 260 varieties collected from America, France, and Germany, in addition to British varieties of every known kind. There were black, red, blue, pink, white, round, kidneys, and flukes, occupying 180 square feet. Owing to the damage by the gale on Tuesday this firm were compelled to remove the greater portion of their plants.

A Banksian silver medal was awarded to Mr. Morgan Williams and the Earl of Carnarvon for groups of vegetables, while Sir Joseph Pease received a silver-gilt Knightian medal for his exhibits in classes 64 and 65.

FLORAL ARRANGEMENTS.

This was an important and beautiful feature of the Show—an exhibition in itself, such as has not elsewhere been seen. In Class 24, for a display of floral arrangements in a space 12 by 5 feet, any design in flowers being admissible, there were four extensive collections staged in almost every device imaginable, including bouquets, wreaths, crosses, anchors, harps, pincushions, lyres, buttonholes, and shoulder sprays. Messrs. Perkins & Sons, Coventry, well deserved the premier honours accorded. They arranged one of the most beautiful displays that has been seen at any exhibition. The centre figure was a tall basket with a hood magnificently furnished with Oncidiums, Dendrobium fimbriatum,

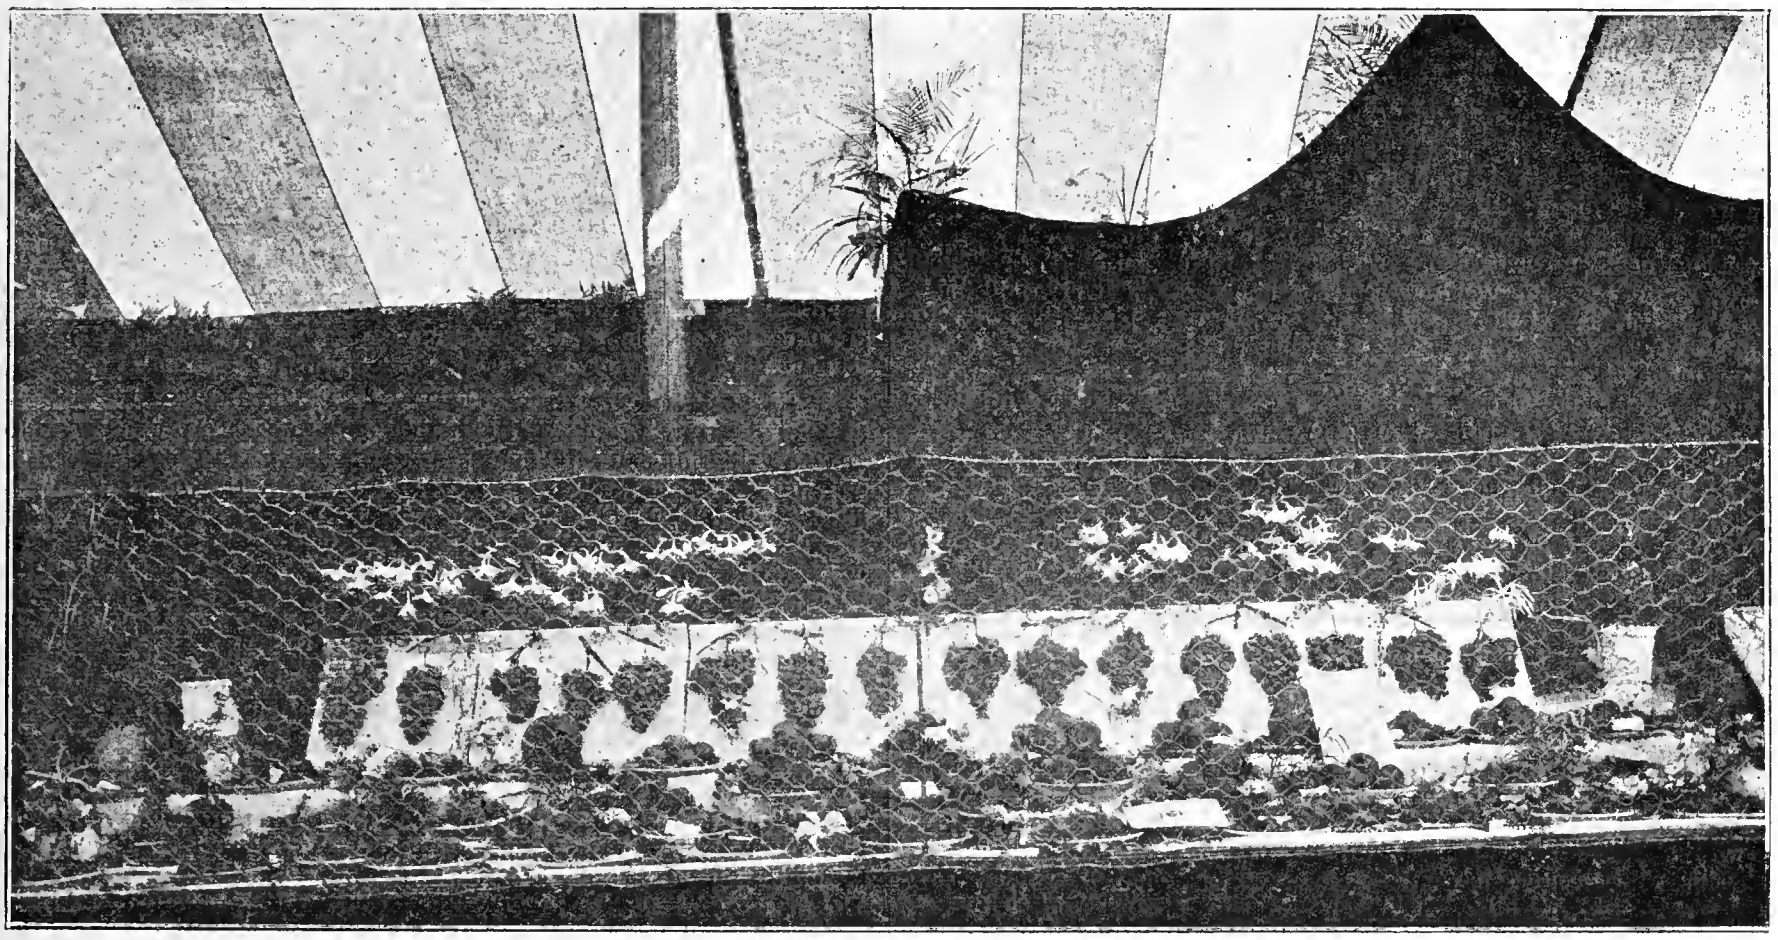

FIG. 26.—MR. J. McINDOE'S COLLECTION OF FRUIT. (*See page* 191.)

Lælias, Cattleyas, and Odontoglossums, associated with long trailing growths of Asparagus plumosus, delicate Ferns, and crowning the whole on the top were feathery sprays of Rhus Cotinus. On the back framework of the stand, which was draped with black velvet, were superb shower bouquets; these, with a huge harp, principally made from white Roses, Lilium Harrisi, white Bouvardias, and Tuberoses, the strings being ornamented with miniature Myosotis blooms, had a most pleasing effect. Further, a pincushion-like base, composed of Violas Countess of Kintore for the borderwork and Max Kolb (blue) for the groundwork, supported a couple of lovely sprays of Odontoglossum Alexandræ, while arranged around as a fringe to the flowers was a margin of Statice, representing a laced border. This was much admired. There were many other attractive features in this wonderful display, such as brackets and epergnes, charmingly arranged, and so graceful in effect as to almost baffle description. The second prize was awarded to Messrs. Jones & Sons, Shrewsbury, whose exhibit contained many highly effective designs. The whole arrangement was set up in the form of an arbour, the supports of which were clothed with Lichen—a novelty certainly, but which in the opinion of several persons did not contribute very much to the effect as a whole. A large harp occupied the centre of the background, while many tastefully arranged shower bouquets, baskets, shoulder sprays, and small epergnes were freely distributed within the allotted space. Miss H. M. Stevens, Great Western Arcade, Birmingham, received third honours, and though her collection had not the finish and lightness of the others, it included many splendid hand and shower bouquets, hearts, anchors, harps, crosses, and baskets of flowers. All four collections formed an extensive and unique display, well deserving of the excellent prizes offered by the Society—viz., £15 first, £12 10s. second, and £10 respectively.

Bouquets.

These were numerous and of a high order of excellence. For a ball bouquet and a bridal bouquet for which £5, £4, and £3 were offered as first, second, and third prizes, three sets of splendid examples were in competition, Messrs. Perkins & Son securing first, Messrs. Jones and Sons the second, and Messrs. Pope & Sons, King's Norton, the third honours. The first prize bridal bouquet was most judiciously arranged with Stephanotis, Eucharis, and long trailing growths of Asparagus plumosus, while in their example for a ball bouquet Oncidiums and Dendrobiums were plentifully yet tastefully used. The second prize display was very much of the same character, but not quite so pleasingly arranged towards the trailing points.

Exhibitors in the foregoing class were excluded from the next class for bouquets in which Orchids were not allowed to be used. Mr. J. R. Chard, Stoke Newington, secured the first prize in this class, his bridal bouquet being principally composed of Pancratiums, white Roses, and Carnations, while in the example for a ball coloured Roses and Carnations with Tuberoses and Pancratiums formed the chief components, assisted with a free use of Asparagus and Maidenhair Ferns. Mr. F. H. Norris, Handsworth, Birmingham, was placed second, and Mr. F. W. Seale, Sevenoaks, third.

It was a very happy idea of the executive to offer substantial prizes in the next three classes for shower bouquets, one composed of Cactus Dahlias, the second of Sweet Peas, and the third of Roses. Such selections teach what can be done with certain flowers unmixed with any others, as well as add a charm and impart variety to an exhibition. A shower bouquet of Cactus Dahlias with any foliage we fear would be considered by many as heavy and ungainly, but that exhibited by Messrs. Pope & Sons consisted of a rosy peach-coloured variety, Countess of Radnor, arranged with a plentiful use of Asparagus plumosus and Smilax, was most pleasing and effective. Mr. W. F. Seale and Mr. J. R. Chard were placed second and third respectively. Eight competitors there were.

Eight exhibitors also tried their skill in arranging Sweet Peas as shower bouquets, and with most creditable results. In that for which the first prize was awarded to Messrs. Pope & Sons lively pink and white varieties preponderated, the effect being very pleasing. Messrs. Proctor & Sons, Chesterfield, were placed second ; and Messrs. D. & W. Croll, Dundee, third.

Seven competitors produced bouquets composed of Roses, with their own foliage. Messrs. Pope & Sons were first for a bouquet of a pink Rose and pure white Tea Roses, a simple and attractive arrangement. Messrs. Perkins & Sons received the second award ; and Messrs. Proctor and Son third.

For a stand of cut flowers for table decoration Mr. R. Chard, Mr. Seale, and Miss F. Kettle, Market Drayton, were placed in the order of their names. Buttonholes and shoulder sprays, six of each, brought several competitors, Messrs. Perkins & Sons, Mr. Chard, and Sir C. E. Isham, Bart., Lamport Hall, Northampton, being placed first, second, and third respectively.

Collection of Flowers.

Collections of Gladioli in a space of 12 feet by 5, nurserymen only, brought two collections. The first prize was awarded to Messrs. Harkness and Son, Bedale, Yorks, for a brilliant display, the varieties being remarkable both for length of spike and breadth of flower. The second prize was withheld, the third being awarded to Messrs. Wallace & Co., Colchester, whose collection contained many of Lemoine's new varieties.

Messrs. D. & W. Croll made a very pleasing arrangement with cut Roses in a space 8 feet by 6 feet. The collection included Hybrid Perpetuals, Teas, Polyanthas, and Moss, the whole of excellent quality. They deservedly received the first prize, and Messrs. Pope & Sons the second.

Dahlias, exhibited in a space 10 feet by 6 feet, produced a brilliant effect. Mr. F. W. Seale took the lead among the other five competitors with a collection including representative varieties of Show, Fancy, Pompons, single, and Cactus effectively arranged. Messrs. Keynes, Williams, & Co., Salisbury, were placed second, and Messrs. Jones and Son third, both exhibiting well, as indeed did others in this fine class.

Seldom, if ever, has such a profusion of hardy herbaceous flowers been set up in competition in the classes confined to nurserymen only. So great was the display made that it almost filled one side of a very long tent. Mr. F. W. Gunn, Olton, Birmingham, was placed first with an admirably arranged collection of meritorious flowers, the absence of crowding enhancing their effect. Messrs. James Cocker & Sons received second honours with a grand lot, and Mr. M. Campbell, Blantyre, N.B., third, also with an imposing display.

For a collection of hardy bulbous and tuberous-rooted flowers in variety, to occupy 12 feet by 6 feet of space, Messrs. Harkness & Sons were placed first, and Messrs. Barr & Sons second. Massive bunches of Gladioli in variety, Liliums, Montbretias, Galtonias, and Alströmerias stood out prominently and attractively in both collections.

A space of 10 feet by 6 feet was allotted for collections of Carnations. Mr. W. Campbell obtained the first place with an excellent assortment of well-known named varieties, as well as several prominent seedlings. Messrs. Laing & Mather, Kelso-on-Tweed, followed very closely as second, and W. G. Philips, Esq., Berwick, Shrewsbury, was a creditable third.

Cut Blooms.

Substantial prizes were provided for forty-eight cut Roses (open) ; and for twenty-four blooms open to county of Salop. Messrs. Cocker and Sons, Messrs. D. & W. Croll, and Messrs. Harkness & Sons received the first, second, and third prizes in the open class with good fresh collections. T. B. Wood, Esq., Ludlow, was placed first in the county class ; Col. Kenyon second, and Lord Trevor third.

Mr. P. Mortimer, Farnham, staged a magnificent collection of twenty-four Dahlias, distinct, and was deservedly awarded the first prize. Mr. B. Brian, Langton, Staffordshire, was placed second, and Mr. Seale third, all having grand exhibits. The best twelve bunches of Cactus Dahlias were staged by Messrs. Keynes, Williams & Co., Mr. Seale being second, and W. E. King, Esq., Leominster, third. For nine Dahlias, amateurs, Mr. Thos. Ellis, Llamlaide, was first, Mr. Abel Lowe second, and Mr. W. E. King third.

Cut stove and greenhouse flowers were represented by numerous collections. For twelve varieties, G. H. Kenrick, Esq., Edgbaston, Birmingham, was placed first, Sir J. W. Pease, Bart., Hutton Hall, second, and Lord Harlech, Oswestry, third. Colonel R. T. Lloyd, Aston Hall, Shrewsbury, staged a splendid box of six varieties and received first honours, F. T. Kynnersly, Esq., Ironbridge, second, and T. B. Wood, Esq., third. Classes were liberally provided for Asters, hardy flowers, Carnations, Picotees, Gaillardias, and Gladioli, most of the classes being open to amateurs in the county. The several flowers well represented and the competition was great.

In the special prize class, offered by Mr. Henry Eckford, Wem, for eighteen varieties of Sweet Peas, there were six competitors, T. Aldersey, Esq., 125, Bellevue, being a good first with the most beautiful and newer varieties. Mr. W. E. Swan was placed second ; and R. L. Kenyon, Esq., Oswestry, third.

For the special prizes offered by Messrs. Jones & Sons for twelve bunches of Cactus Dahlias Mrs. Watkins, Shrewsbury ; W. E. King, Esq., and the Rev. T. M. Bulkeley Owen shared the honours in the order of their names. Other special prizes offered by Messrs. Clibran & Sons, Altrincham, and Mr. A. Myers, Shrewsbury, were also keenly contested.

Fruit.

The competition in the fruit classes is always remarkably keen at Shrewsbury. This year proved no exception to the rule, and many fine exhibits failed to secure a place ; indeed it may be truly said that to win in any of the classes was a great honour, to lose no disgrace. How close in point of merit some of the collections were to each other will be readily seen by the pointing given below.

Decorative Dessert Tables.

The conditions were that each table be decorated with plants in pots not exceeding 5 inches in diameter, and not more than sixteen dishes of fruit to be staged, these to be selected at the discretion of exhibitor from a list given in the schedule.

The premier award, after a close contest, was won by Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby. His arrangement was light and well executed, and his fruit superb. The centre was formed of a circular piece of plate glass, surrounded with green Selaginella, from which Orchids, Grasses, and Asparagus plumosus sprung in a charmingly natural manner. Two other trumpet-shaped glasses were arranged, with Masdevallias and Asparagus deflexus trailed lightly upon the cloth. The Grapes were arranged on rustic stands at the four corners, but these were faulty, as their backs—which must of necessity face some of the guests at the table—were the reverse of ornamental. The whole forming a nicely balanced and suitable arrangement, and although the fruit was fine, and in every way worthy of its great exhibitor, a perusal of the pointing will show that it was in the artistic part of the work that he managed to turn the scales upon his opponent.

The second prize was well won by Mr. J. McIndoe, gardener to Sir J. W. Pease, Hutton Hall, Guisboro', with a somewhat taller arrangement. A fine Pine formed a centre, a tall trumpet glass being placed on either side ; eight small glasses were disposed round the sides of the table. The Grapes were arrranged in baskets at each end. The glasses were furnished with Asparagus deflexus and Montbretias. Every dish of fruit was of attractive appearance, the superb half dozen of Golden Eagle Peach being the most handsome in the whole Show.

Result of Judges' Awards.

Totals	105½	104½

The third position was secured by Mr. Harris, gardener to Lady Henry Somerset, Eastnor Castle, Ledbury, for fruit and an effective arrangement, which received 99½ points, Mr. Gleeson, Stanmore, coming fourth with 96½ points. Five exhibitors competed.

Victorian Fruit Class.

To illustrate the produce of British gardens three prizes were offered for sixty dishes of fruit arranged on side tables, in a space 16 feet by 4 feet 6 inches, artistically displayed with cut flowers, foliage, and not more than twelve plants in pots not exceeding 5 inches in diameter. The fruit had to be selected from a list given in the schedule, the whole to be judged by points up to the maximum for each kind in the R.H.S. Code, 1896, a maximum of twenty-four points allowed for decoration and artistic arrangement. The first prize was the handsome one of £30 and the gold medal of the Worshipful Company of Fruiterers; second, £25 and the silver-gilt Knightian medal of Royal Horticultural Society; third, £20 and the silver medal of the Shropshire Horticultural Society.

Three doughty champions entered the fray, and tough work the Judges must have had in deciding on the relative merits of the collections in this the greatest fruit class on record, the number of dishes stipulated for corresponding with the years of her Majesty's reign. Evidently no pains were spared by the adjudicators in scrutinising every dish, and the result of their decision met with general approval, which indeed it could scarcely fail to do, as it was arrived at by method and calculation as in the previous class, in other words, by scientific judging. The winners of the prizes were :—Mr. McIndoe, first (and a proud and happy man he seemed); Mr. R. Dawes, gardener to Mrs. Ingram, Temple Newsam, second, Mr. Goodacre being a close third. Below is given a detailed account of the "pointing," and a description of each collection separately.

The style of arrangement adopted in Mr. McIndoe's collection was a fairly good one. Crotons and Palms were arranged at the back of the Grape stands, with bunch-like masses of Eucharis amazonica and Montbretia crocosmæflora springing up between; Orchids, light pieces of Ampelopsis Veitchi, and Maidenhair Fern being placed between the dishes.

The collection, on the whole, was a superb one, well worthy to win so unique and coveted a prize. If there were a weak feature about it, it was found in the white Grapes, which would have been better for a little more fulness of bunch and brightness of colour. Black Grapes were, however, good, so also were the Pines. The reason why only twelve points are recorded for the Pines in this collection is that it only contained two fruits, while in each of the other collections four were staged. Each one of the fruit dishes was, however, in grand condition, and fairly returned the exhibitor the winner by a good majority of points.

The Grapes were Bowood Muscat (two), bunches slightly loose; Duke of Buccleuch (two), good; Buckland Sweetwater, one large compact bunch, the other somewhat smaller, neither really well coloured; Muscat of Alexandria, one loose bunch, the other compact and well coloured; Black Hamburgh (two), very large and finely proportioned, but not quite perfect in colour; Gros Guillaume (two), medium size, shapely, beautifully coloured; Gros Maroc (two), grand in both bunch, berry, and colour; Alnwick Seedling (two), good size of bunches, perfectly finished. Melons (four): One variety being Magnum Bonum, 5 or 6 lbs. in weight, well netted; Scarlet Premier; Darwin, bright and good; and Scarlet Model.

Five dishes of Peaches were staged, the varieties being Violette Hâtive, good; Golden Eagle; good size, fine in colour; Exquisite, large, but not quite ripe; Stirling Castle, highly coloured, grand in every way; and Royal George, good in size and colour. Of Nectarines there were also five dishes, one a duplicate. The varieties were Stanwick Elruge, grand; Pitmaston Orange, large and good; Lord Napier, large; and Spencer, superb.

Pines were represented by a good and well ripened Smooth Cayenne and a Queen of fair size, beautiful shape, and colour. Of Apricots there were three varieties, Kaisha, Large Early, and Moor Park.

Plums were shown in exceptionally good condition, the varieties being July Green Gage; Golden Gage, grand; Boddaert's Green Gage; Decaisne, a fine variety not often seen in such good condition; and Burbank, a new Japanese variety of great promise, the fruits being large, highly coloured, and luscious looking.

Pears made a fine show, the varieties being Marguerite Marrillat (new), Souvenir du Congrès (two), Pitmaston Duchess (two dishes) grand; and Selous. Tomatoes Green Gage (yellow) and The Queen (red) were very large and showy. Of Figs there were three dishes, two being Brown Turkey, and the other Negro Largo.

Apples were numerously and grandly shown. The varieties were James Grieve, beautiful; Washington, grand; Gascoyne's Scarlet, superb, consisting of very large, brilliantly coloured fruits; and Duchess of Gloucester, wonderfully bright and good. The other dishes were Bigarreau Napoleon Cherry, Kentish Cob Nuts, Orange Exquisite, Lemons, Gooseberry Whinham's Industry, Currants White and Red Versailles, and a cluster of Musa Cavendishi. The photographic illustration (fig. 26, page 189) represents this exhibit.

The collection which won second honours was also a very fine one, although it did not run the premier exhibit particularly close. Its strong points were Grapes, Peaches, Nectarines, Pines, and Bananas, but only six points were awarded for decoration and artistic arrangement. The Pines were arranged on wire stands covered with moss and decorated with yellow flowers, Asparagus plumosus and Hollyhocks being arranged between the dishes. The effect was, however, altogether too stiff.

The kinds and varieties of fruits staged were—Grapes, Gros Maroc, two bunches, grand alike in bunch, berry, and colour; Foster's Seedling (two), of fair size and colour, berries rather small; Gros Guillaume (four), bunches large, perfect in shape and superbly coloured; Muscat of Alexandria (four), two of them were large and well shaped, the remaining two somewhat small, all wanted a little more colour; Madresfield Court (two), large, well shaped bunches, rather deficient in colour; Buckland Sweetwater (two), grand in both bunch, berry, and colour. Pines, one Smooth Cayenne of moderate size; three Queens, good. Melons, seedling, large, well netted and coloured, Reid's Scarlet-flesh; Temple Newsam Hybrid, beautifully netted; and Golden Gem.

Peaches, Goshawk, one dish, fair; Dymond, one, large and good; Bellegarde, even and well coloured; Barrington, fine colour, good size; Violette Hâtive, and Grosse Mignonne. Among Nectarines there were superb examples of Lord Napier, Spencer, and Humboldt. Pears were represented by good dishes of Souvenir du Congrès, Clapp's Favourite, Williams' Bon Chrêtien, and Jargonelle. Three dishes of Figs were staged, one being Negro Largo, the others fine examples of Signorina. Plums, Golden Gage (two), Early Prolific, Transparent Gage, of wonderful size, and Kirke's. The Apples were Red Astraehan, Thorpe's Pippin, and Irish Peach; the remaining dishes consisting of Moor Park and Large Early Apricots; Gooseberries, Dan's Mistake (red) and Plunder (green); Strawberry, Late Pine; Tomatoes (red), Challenger and Ruby; Cherry, Late Duke; Red Currants, and a grand cluster of Bananas. Mr. Goodacre was a dangerously close third. His collection was strong in Grapes, Melons, Apricots, and Pears; but many of his fruit dishes fell away considerably from the standard maintained in the collections of his successful opponents. For artistic arrangement, however, his exhibit secured the greatest number of points. In this instance light and graceful plants were arranged at the back of the Grape stands, Carnations being arranged in glasses between them and Orchids at intervals between the dishes of fruit. Tufts of Selaginella were also disposed at intervals along the front of the table, upon which Lapageria flowers were placed.

Some of the most noteworthy dishes in the collection were Grapes. Black Hamburgh (two bunches), beautifully coloured; Gros Maroc (two), superb in every way; Muscat Hamburgh (two), splendid in size and colour, for the variety; Gros Guillaume (two), large, shapely bunches, good in size, perfect in colour, but slightly rubbed; Duke of Buccleuch (two); Foster's Seedling (two); Muscat of Alexandria (two), large, full and shapely, slightly wanting in colour; two others of same variety being large, full, and well coloured. Melons were fine, Frogmore Scarlet was perhaps the finest specimen in the show. Countess and Hero of Lockinge were also good. A grand dish of Princess of Wales Peach should also be noted.

Collection of Fruit.

For nine dishes, not less than five kinds, nor more than two varieties of a kind, £5 and the silver medal of the Worshipful Company of Fruiterers was offered for the first prize, £3 for the second, £2 for the third, and £1 for the fourth. Seven good lots were staged. Mr. S. Bremmell, gardener to H. H. Francе Hayhurst, Esq., Overley, Wellington, Salop, was a good first, showing Muscat of Alexandria and Gros Maroc Grapes (the bunches of the former being large and fairly well coloured, the latter good in every way), a fine and well netted Melon, good Royal George Peaches, Williams' Bon Chrêtien Pear, Figs, Apricots, and Nectarines. The second prize went to Mr. G. Bible, gardener to Lord Trevor, Brynkinalt, Chirk, whose best dishes were well-coloured Black Hamburgh Grapes, a beautiful Melon The Countess, and grand Barrington Peaches; the third position being occupied by Mr. J. Langley, gardener to Rev. T. M. Bulkeley Owen, Tadsmore Hall, West Fenton; and the fourth to Mr. C. Roberts, gardener at Halston Hall, Oswestry.

Silver Medal Grape Classes.

The handsome prize of £6 and the silver medal of the Fruiterers' Company were offered for the best four bunches of black Grapes, to consist of two bunches of two varieties; other prizes of £4, £3, and £2 being also offered in the same class. The coveted award was secured by Mr. G. Davies, gardener to Rev. F. Anderson, Welsh Frankton,

Oswestry, who staged Black Hamburgh, in large clusters, quite black, and Gros Maroc, large in bunch and berry and good in colour. Mr. T. Lambert, gardener to Lord Harlech, Oswestry, came in second with Gros Maroc, in very fine condition, and Madresfield Court, large in bunch and berry, but wanting in colour; the third position being occupied by Rev. T. M. Bulkeley, who staged Madresfield Court and Black Hamburgh, both large in bunch but not well coloured. Fourth, Mr. J. Skitt, gardener to Mrs. Bright, Ashfield, Liverpool.

For four bunches of white Grapes, in two varieties, the prizes offered were of the same value as those in the preceding class. Seven good lots were staged, the first prize being deservedly awarded to Mr. J. Campbell, gardener to C. E. Newton, Esq., Mickleover Manor, Derby, who had well coloured examples of Muscat of Alexandria and Canon Hall Muscat. The second prize went to Mr. J. Lambert, who staged large bunches of Muscat, rather green; fine solid bunches of Buckland Sweetwater, fairly well coloured. Third, H. B. Marling, Esq., Clanna, Lydney, Glos., the varieties staged being Buckland Sweetwater, fine in bunch, deficient in colour; Muscat, compact in bunch, colour fair. Mr. Carr, gardener to Sir O. Wakeman, Yeaton, Salop, secured the remaining award.

Other Grape Classes.

Mr. Bremmell was first for two bunches of Black Hamburgh with compact beautifully finished examples, Mr. F. Harris being second, and Mr. F. Barnes, gardener to the Duke of Westminster, Eaton Hall, Chester, an extremely close third. Fifteen lots were staged. For two bunches of Madresfield Court, Messrs. Langley, Skitt, and Barnes secured the prizes in the order named, in each case with examples showing high culture. Mr. G. Davies secured the first prize for two bunches of Black Alicante with superbly coloured clusters; the second award going to Mr. Goodacre for shapely examples, and the third to Mr. A. H. Hall, gardener to J. E. Waterhouse, Esq., Macclesfield. Nine exhibits were tabled in the class for two bunches of Gros Colman or Gros Maroc. Mr. Goodacre was to the front with handsome and superbly finished bunches of Gros Maroc; second, Mr. T. Lambert; third, Mr. F. Jordan, gardener to J. Corbett, Esq., Impney Hall, Droitwich.

Ten lots of Muscats were tabled, the premier award going to Mr. W. Neild, Holmes Chapel, Cheshire, for full heavy bunches, not well coloured; the second to Mr. W. Fyfe, gardener to Lord Wantage, Lockinge Park, for large bunches, even in berry, but rather flat; and the third to Mr. J. Campbell, who had compact bunches, fairly good in colour. The class for two bunches of white Grapes, any other variety, was not a good one, want of colour being noticeable. The prizes in each instance were awarded to large bunches of Buckland Sweetwater, and were secured by Messrs. G. Davis, J. McDonald, and R. Lawley, in the order named.

Miscellaneous Fruits.

Sixteen fine dishes of Peaches were staged. A grand one of Sea Eagle won for Mr. J. Robinson, gardener to R. W. Harley, Esq., Herefordshire, the first prize. The second went to Mr. Tyler, gardener to C. A. Jones, Esq., Bron, Hendre, for fine Barrington; and the third to Mr. B. Ashton, gardener to Lord Lathom, Ormskirk, for Royal George. Of Nectarines there were twelve dishes. The best came from Mr. F. Harris – variety Pitmaston Orange; Mr. McDonald being second; and Mr. Wilkes, gardener to Mrs. Meakin, Cresswell Hall, Staffs, third.

For six Apricots Mr. F. Bible won, and for twelve Plums, green or yellow, Mr. Pope. Twenty-one green-fleshed Melons were staged. Mr. F. Tugwood was first with an unnamed seedling; Mr. Birch, gardener to Mrs. Watkins, Shotton Hall, second with Earl's Favourite; and Mr. C. Mee, Nottingham, third. In the class for scarlet-fleshed ones nineteen were set up, the premier award going to Mr. R. Townsend; the second to Mr. J. Durnell, gardener to R. Kenyon, Esq., Oswestry; and the third to Mr. C. Bellis. Mr. Bremmell won for a single dish of Cherries.

Local Classes, Open to the County of Salop.

Two bunches black Grapes.—First, Mr. Langley, shapely bunches, good colour. Any other variety, black, two bunches.—First, Mr. Carr The same exhibitor won for two bunches of Muscats, and for the same number of any other white Mr. R. Lawley was the winner. Mr. R. Townsend was first for six dishes of hardy fruits, being followed by J. Wood, Esq., Henley House, Ludlow; and Mr. E. Walker, in the order named.

VEGETABLES.

The display of vegetables at this exhibition was one of the most remarkable that has been seen both on account of the high quality and the quantity that were staged. Magnificent examples were shown in the several classes in which the leading seedsmen offered generous awards, and in some cases the merits of the different collections were very close indeed. Not only was this excellence noticeable in the stands of our leading growers but also in those of the cottagers of the district, who deserve the highest credit for the standard to which they have attained. All kinds of vegetables were exhibited in both sections, and there can be little doubt, that taken as a whole, it was one of the finest exhibitions that has ever been seen either at Shrewsbury or elsewhere.

In some former years it has been said, and justifiably, that size was thought too much of by growers and Judges. This show, however, brought a radical change in this respect, for quality was unquestionably to the front. Of course some few coarse specimens found a place on the tables, but this was rather an advantage than otherwise, as it served admirably to accentuate the excellence of the others. It was clearly apparent that the Judges had sought for quality and made size a secondary consideration only. This we were glad to see, as there can be no question that some of the vegetables shown here and elsewhere were very much too large for the purposes for which they were supposed to be grown. It was an impossibility to get the whole of the awards that were made, and we have given therefore the prizewinners in a few of the most important classes only.

The principal class was that for nine distinct kinds of vegetables grown from seeds supplied by Messrs. Sutton & Sons, Reading. In addition to the six money prizes there was a valuable silver Jubilee commemorative cup. So good were the examples staged that the Council of the R.H.S. adjudged a silver Banksian medal to the first prize stand. There were eleven exhibitors, and Mr. C. Foster, gardener to Morgan S. Williams, Esq., Aberpergwm, Glyn Neath, succeeded in carrying off first honours. As a whole, the stand (fig. 28, page 201) was clean and even, with no coarseness in the products. It was comprised of Solid White Celery, Autumn Mammoth Cauliflower, Prizetaker Leek, Selected Ailsa Craig Onion, New Red Intermediate Carrot, Blood Red Beet, Satisfaction Potato, Perfection Tomato, and Prizewinner Runner Bean. Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury, was second with a stand almost equally as good as the preceding one. The best dishes were Sutton's Best of All Bean, Autumn Mammoth Cauliflower, Prizetaker Leek, and Satisfaction Potato. Mr. J. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, Basingstoke, was third; Mr. C. J. Waite, gardener to the Hon. W. P. Talbot, Glenhurst, Esher, fourth; and Mr. T. Wilkins, gardener to Lady Theodora Guest, Inwood House, Henstridge, fifth.

In Messrs. Webb & Sons' class for eight distinct kinds there were six exhibitors, of whom Mr. Wm. Pope was awarded first position. A silver Banksian medal, in addition to the prize, was awarded. This exhibitor staged Early Mammoth Cauliflower, Improved Banbury Onion, Defiance Carrot, Jubilee Tomato, Satisfaction Potato, Pink Perfection Celery, Duke of Albany Pea, and Eclipse Bean, all in capital form. Mr. J. Bowerman was second, his best examples being Ailsa Craig Onions, Eclipse Beans, and Progress Potatoes. The third and fourth positions were taken by Messrs. T. Wilkins and C. J. Waite in the order of their names.

For the valuable prizes offered by Messrs. Carter & Co. to growers resident in certain English counties or in Wales there was keen competition, eight collections being staged. Mr. R. Milner, gardener to Miss Talbot, Penrice Castle, Swansea, was a highly creditable first with Model Leek, Solid Ivory Celery, Autumn Giant Cauliflower, Jersey Lily Turnip, Ailsa Craig Onion, Duke of Albany Pea, Supreme Potato, Intermediate Carrot, and Perfection Tomato. A bronze Banksian medal was also accorded this collection. Mr. R. C. Townsend, gardener to Colonel R. T. Lloyd, took second place with good Celery, Onions, Peas, Runner Beans, Tomatoes, and fair Leeks, Cauliflowers, and Potatoes. Mr. J. Birch was placed in the third position, Mr. H. Taylor in the fourth. Mr. W. Prior in the fifth, and Mr. S. Bremmell in the sixth.

Mr. E. Murrell offered prizes for twelve distinct vegetables grown from his seeds, these being taken by Messrs. J. Robinson, P. C. Townsend, and J. Birch in the order named. Mr. Birch succeeded in winning Messrs. Pritchard & Sons' special first prize, followed by Mr. Bellis and Mr. J. Delamere.

In the class for a collection of Potatoes, five dishes, there were fourteen exhibits staged, Mr. C. Foster winning with Windsor Castle, Boston Q. Q., Abundance White, Reading Russet, and Tennyson coloured. Mr. Aston was second with Goldfinder, Reliance, A1, Mr. Bruce, and Reading Russet. Mr. W. Pope took the third place. There were twenty stands of three dishes staged, Mr. Foster winning with Abundance, Satisfaction, and Windsor Castle, followed by Mr. W. Pope and Mr. T. Wilkins. For the single dish twenty-two staged, Mr. C. J. Waite taking first with nice tubers of Windsor Castle.

Tomatoes were good. Mr. A. H. Hall was first with Perfection, Mr. Foster and Mr. Risebrow following in the order named with the same variety. Cucumbers were not very good. Mr. Hall staged the best brace in Diamond Jubilee, Mr. Risebrow and Mr. Wilkins following. Peas were a good class, Mr. Cuckner and Mr. Bible being the winners. French dwarf and runner Beans were also staged in goodly numbers, Mr. G. Davies winning for dwarfs and Mr. Atkin for runners. Mr. Pope won for three Cauliflowers; Mr. Abbot for Celery with fine sticks of Solid White. Parsnips, Carrots, and Turnips were staged in large numbers. Mr. C. J. Waite took first for Parsnips with fine Student, Mr. Foster won for Carrots, while Mr. Townsend was first for Turnips. Onions were well staged, Mr. Foster and Mr. Waite winning in the respective classes for spring and autumn sown.

Mr. Sydenham offered special prizes in a number of classes. In that for four varieties of Peas Mr. T. Griffiths took first place with Autocrat, The Queen, Duke of Albany, and Prince of Wales. Mr. E. Walker was second, and Mr. Wm. Leath third. For two dishes of Onions, one Excelsior and one Tripoli, Mr. Wm. Leath was first, and Mr. W. Pope second. For two dishes of nine Tomatoes Mr. Leath was successful in winning, followed by Mr. Wilkins. Mr. Pope won for Cauliflowers and Beans, and Mr. Wilkins for Carrots.

LUNCHEON—PRESENTATION TO THE HON. SECRETARIES.

Shortly before two o'clock on Wednesday the visiting members of the Royal Horticultural Society, the Judges, the members of the Committee, and other officials assembled for lunch. Lord Kenyon, as President of the Shropshire Society, occupied the chair. The Royal

toasts having been duly honoured, the Chairman, in appropriate terms, proposed "The Royal Horticultural Society."

Sir TREVOR LAWRENCE, whose name was coupled with the toast, first mentioned with pleasure that Lord Kenyon had asked him to propose him as a member of the Royal Society. He proceeded that though the elements were to some extent in a conspiracy against the Show the previous day, they must agree that the efforts that had been made to overcome the disaster which took place had been crowned with success. The visits which the Royal Horticultural Society had made during the last two years to the provinces had been made with a view to drawing nearer the ties which bound the Society in London with the societies which existed all over the country. They felt that the parent Society should encourage horticulture all over the kingdom, and by visiting York, Shrewsbury, and other places they hoped to be able to do that. With regard to the Shrewsbury Show, he offered them his very sincere congratulations. (Applause.) He had heard a great deal about the splendour of the Shrewsbury Shows, but he did not believe till he saw it that they could have got together so fine an exhibition as they had that day. (Applause.) The Royal Horticultural Society which had had its ups and downs, was very near its centenary. If they looked back to the work it had done to advance horticulture in this kingdom—particularly in the introduction of new plants and in the instruction of gardeners—they must say it had done work of enduring excellence. (Applause.) He believed there was no part of the kingdom where they could walk more than a few yards without coming across plants which had been introduced through that Society. He acknowledged the support given them by the amateurs of the kingdom, and the gratuitous services of the best horticulturists throughout the length and breadth of the land, and took that opportunity of returning them grateful thanks. With her Majesty's permission, he added, they had established this year a Victoria medal, which they believed would be of considerable value. It might not perhaps be so valuable as the two medals given by Lord Kenyon that day, which he understood could not be reproduced, and which were of very beautiful design. He believed they were designed by a lady, as was also their Victoria medal. Having thanked the local Society for the kind reception they had given the Royal Society,

Sir TREVOR LAWRENCE, on behalf of the exhibitors at the Shrewsbury Show and friends, presented each of the Hon. Secretaries (Mr. W. W. Naunton and Mr. H. W. Adnitt) with a large and handsome silver and cut glass epergne. The epergnes bore inscriptions testifying that they were presented to Mr. W. W. Naunton and Mr. H. W. Adnitt by the exhibitors and friends attending the shows of the Shropshire Horticultural Society during the last twenty-two years in appreciation of their faithful services as Hon. Secretaries. Sir Trevor added that those who knew the trouble of arranging these exhibitions would feel that after twenty-two years' service not only should these epergnes be presented, but they should be full of sovereigns as well. (Applause.)

Messrs. ADNITT and NAUNTON both suitably responded, alluding to the pleasure with which they had worked for the Society for so many years, and thanking the Committee who had arranged the presentation, and the Hon. Treasurer (Mr. O. Thomas) and the Hon. Secretary (Mr. A. Outram) for the trouble they had taken in connection with it. Mr. Naunton mentioned that there had now been twenty-three shows, and neither he nor his colleague had ever been absent one hour.

Dean HOLE, addressing the company as his brethren and sisters in the most charming of all arts and the purest of human pleasures, said they must be few who could remember, as he did, the old times at the beginning of the Victorian era—the dismal trees in tubs and lanky plants, the stoves and greenhouses with long roofs and decaying rafters and tiny discoloured panes, and within and over all flies and red spiders and mealy bugs reigning in glory. (Laughter.) In one or two of their choicest collections there were half a dozen Orchids in their green and yellow melancholy, looking at one as the Roman gladiators looked at the Emperor when they presented the compliments of dying men. (Laughter.) The queen of flowers, like the Queen of England, was just stepping on the throne of her development in beauty. (Applause.) The gardener of sixty years ago was a superior sort of man, clever, shrewd, industrious, and honest as the day; but he was the biggest tyrant and the greatest autocrat that ever breathed. (Laughter.) The fact was that nobody knew anything about gardening, and they dared not contradict him. Worse than that, they were even proud of their ignorance, and they went and stopped the growth of his plants, and excited not only his compassion but his indignation. And when he found them out he had seen this—that man would stand in the presence of the proprietor and proprietress and their guests and let them have such a lecture as made their knees knock together. (Renewed laughter.) The gardener of the present day was, for his own and other people's happiness, a very different man, though there were some terrible exceptions. He was far more appreciated than ever he was. People had sympathy with his art; throughout England his power was recognised in the preparation of things pleasing to the eye and good for food. The time came, said the speaker, in conclusion, when other things failed, but the garden never failed them, and as they grew older it became more and more the consolation of their life. He hoped the show that day might induce others to interweave with their lives that golden thread of a love of horticulture, which added so much to its pure and permanent happiness. He then proposed "Success to the Shropshire Horticultural Society," to which the Mayor of Shrewsbury eloquently responded. The proceedings terminated with the "Health of the President," and Lord Kenyon, in replying, mentioned that his medal was designed by the Countess Feodore Gleichen.

COMMENTS ON THE SHREWSBURY SHOW.

I HAVE no intention whatever to intrude into the reporter's domain in connection with the products of this truly grand exhibition, but I do feel that there is space to make some general references that may merit notice. In your recent references to the Shropshire Society mention is made of the wonderful local benefits that have resulted from the shows, and the great surplus they have produced from time to time. With the recollection of that disaster to the great plant tent full upon us, a disaster so soon and so effectively recovered from by British pluck and activity, I can but think the Society would find an object worthy of its ambition in the erection on the site of the dismantled tent of a noble pavilion, which could be utilised in winter as a concert hall or musical promenade, being at the same time a sort of winter garden; and then might be available for the purposes of the flower show as a grand plant centre when needed. What fine effects could be obtained in such ease. If on either side there could run off a long broad covered promenade, which might also be utilised for show purposes, and from out of these could run tents for the remainder of the exhibits, thus bringing the entire show under one roof as it were, what a boon would it be, and how remarkably effective the result. Without exception the grandest of all provincial shows, that of Shrewsbury, loses so much by its wide distribution. Could the finest of the exhibits be more concentrated, how much would the show gain!

The decorative groups are there so beautiful and in design largely so original that they become veritable works of art, that are alone worth travelling long journeys to see. To numbers of gardeners a sight of these groups must come as revelations of what is possible with even comparatively ordinary exhibits. Arrangers now seem to find it difficult to excel themselves. But somehow, perhaps because they seem to belong to the exhibition ideas of a past age, the big specimen plants now attract little attention. If I were to ask, Are they worth preserving? I think the majority would answer No. For one visitor who stops to scrutinise them twenty stop to study the very beautiful groups, whether in or out of competition, with the greatest interest. Compared with what used to be seen in the palmy days of Baines and Cole the finest show plants of to-day seem poor. They may be good, but the old appreciation of them is gone. The public needs something more up-to-date now to satisfy its rather exacting requirements.

The introduction of the point system in awards, and their publication for the benefit of all concerned, if giving to the judges some additional trouble, yet cannot give much extra, seeing that in relation to the two great classes concerned it would not be possible to arrive at any correct conclusions except on a pointing basis. As an apostle of a just but hard to obtain regulation, very much indeed one crying in the wilderness, I could but think, seeing that in the dessert table class for instance the total ordinary prize money amounted to £38 17s., what a splendid opportunity was here offered to make the money prizes exactly commensurate with the actual point value of the exhibits. Mr. Goodacre comes with 105½ points, and besides the Veitch Memorial medal receives £17 12s. Mr. McIndoe is but one point behind, and he receives only 12 guineas. Had the whole of the cash inclusive of the Veitch Memorial £5 been pooled and then shared according to actual point merit the cash values would have been very different.

There is an impression that this method of prize-sharing would discourage competition. That is all nonsense. Rather it would tend to stimulate it. I should like to see the Shrewsbury executive, a body that can afford so well to lead, establishing just one class on this principle, and one of six vegetables, six outdoor fruits, and six bunches of garden flowers, all distinct, and in one group, would make a capital open one for a *corpus vile*. I noticed in the cottagers' tent a couple of wonderfully pretty objects of wild flowers on tripods shown as baskets that were disqualified, but which, if admitted, would have been well first. Baskets in the ordinary acceptation of the term they were not, but rather basket-trays. Could not the words "trays" or baskets be included in the conditions next year? As to the wild flower arrangements generally, they were the handsomest I have ever seen.—A. D.

STRAWBERRY LORD SUFFIELD.

I WAS much interested with the article on Strawberries by "A Young Scot" in the "Gardeners' Domain," in your issue of the 12th, but with the judgment pronounced on Lord Suffield by the writer I do not at all agree. In our light free soil I find it to be a first-class Strawberry in every respect. The size is all that could be desired, being quite as large as Royal Sovereign, and having very few small fruits. The colour is magnificent, bright red to the very tip. But one of the best features is firmness of flesh, and it therefore does not suffer from damp so readily as many other varieties. To be pronounced coarse by any grower astonishes me, but it may be the treatment of the plants that makes all the difference in quality.

Immediately the fruit is gathered we take a spade and run it up each side of the row to cut all runners, and also run the hoe through between the rows to clear off weeds. I find little more attention is needed until November, then we give them a heavy mulch of cow manure. About the beginning of April a dusting of soot is given to check slugs, straw is then laid in between the rows, and our plants never show any signs of suffering from drought.—R. K. PATERSON, *Linlithgow*.

Notes & Gleanings

Weather in London.—Rain has fallen at frequent intervals on almost every day of the past week, and at times the showers have been very heavy indeed. Tuesday was perhaps the worst day, as it rained almost without cessation from eight o'clock in the morning until after midday. Wednesday morning was cool and dry, rain falling heavily later.

—— Gardening Appointments.—Mr. Geo. Hollingworth, for some time gardener to Lord Tredegar, Tredegar Park, Newport, Mon., has been appointed in a similar capacity to Miss Talbot, Margam Park, Port Talbot, Glamorgan, in succession to Mr. J. Muir, who, we believe, has been made assistant agent. Mr. J. Bannerman has been appointed gardener to J. Lawrence, Esq., Oakland, Kenley, Surrey.

—— Shirley, Millbrook, and Freemantle Horticultural Society. The thirty-second annual Exhibition of the above Society was held on the 18th inst. in Whithedwood Park, Shirley, Southampton, kindly lent by W. Perkins, Esq., J.P. The entries were over 600, and the exhibits were staged in two large marquees. The quality of the exhibits was high, and the attendance a record one.

—— Outdoor Tomatoes.—When visiting the well-kept gardens of R. Wingfield, Esq, Ampthill House, Bedfordshire, I was much struck with the Tomatoes Mr. Empson had planted round the outside of the several houses in a southern aspect. The plants have made splendid growth and are carrying superb crops of fruit, especially good being Chiswick Red, Polegate, Hackwood Park, and last but not least Viceroy, a variety which should be much more largely grown. In one of the houses a plant of Stephanotis floribunda was one sheet of bloom.—J. H. L.

—— National Chrysanthemum Society.—A meeting of the General Committee of this Society was held on Monday evening last at Anderton's Hotel, Fleet Street, when Mr. T. W. Sanders occupied the chair. The minutes of the previous meeting having been read and confirmed, and various correspondence disposed of, it was announced by the Secretary that a vote of condolence had been forwarded to the family of the late Mr. Robert Owen, who it will be remembered died suddenly somewhat early in the year. Owing to this sad event a vacancy on the Floral Committee was created, and it was resolved that Mr. Gleeson be apppointed to fill the vacancy. The Secretary reported as to the annual outing last month, which was described as a successful and interesting excursion. Respecting the early show of Chrysanthemums, Dahlias, and Gladioli, to be held next month, it was resolved that medals of the Society be awarded to miscellaneous exhibits in the same way as at the other shows. Twenty-five new members were elected, and the Higham Hill and Walthamstow and the Barnstaple Societies were admitted in affiliation. There was a fair attendance of members for the time of year.

—— Portulacas at Reading.—The most brilliant display of these truly lovely flowering summer annuals I have ever seen is now open to view to anyone in Messrs. Sutton & Sons' London Road Nursery, Reading. Hitherto their show of these flowers has been restricted to an 18-inch margin, just within the nursery. This year they have a border 6 feet wide and some 120 feet long farther into the nursery, literally covered with single and double varieties, and when I saw the mass on a bright sunny day recently it presented the loveliest of floral beds that could anywhere be seen. Those who know Portulacas, know also what singularly beautiful hues are found in the flowers. No matter whether double or single, although I prefer the singles, there are the whites, creams, yellows, apricots, roses, carmines, magentas, scarlets, crimsons, and others not easy to describe. Then, too, it was always a traditional aspect of the raising of Portulacas that seed be sown in shallow pans in warmth under glass, the little plants later being pricked out into other pans to give growing room, then finally transplanted into the open ground. A maximum of trouble was thus given, and oftentimes with great damping off as a result. The Messrs. Sutton & Sons have practically killed that objectionable tradition, for they sow seed in shallow drills on a warm border at the end of April, keep the surface clean and moist. If the plants be too thick they may be somewhat thinned, but if sown with care no trouble on that head will be given, and very soon one of the loveliest conceivable of floral carpets will be found.—D.

—— Veitch's Main Crop Pea.—This splendid midseason Pea has undoubtedly come to stay, and should speedily secure a place in many gardens. The plant is of robust constitution, produces heavy crops of large pods, and only attains a height of 3 feet. In fact, it supplies what we have long required—viz., a main crop Pea of dwarf habit, possessing at the same time all the good qualities of the taller growing varieties. In addition, Veitch's Main Crop withstands drought better than any variety I am acquainted with, notwithstanding the fact that the present season has put it to a severe test.—H. D.

—— Shirley Gardeners' Association.—The monthly meeting was held at the Parish Room, Shirley, on Monday, the 16th inst., when Mr. B. Ladhams, F.R.H.S., presided. Mr. S. Heaton, F.R.H.S., lecturer for the Isle of Wight County Council, gave an address on the diseases of plants. The lecturer dealt with the subject under three headings—namely, parasitic and insect attacks; second, deleterious gases in the air or otherwise produced so as to affect nutrition; and third, a redundancy or deficiency of air, light, moisture, and warmth.

—— Big Gooseberry Competition.—A novel competition, which may be regarded as an appropriate incident in this the "Big Gooseberry" season, was held last week by Messrs. Stuart & Mein, seed merchants and nurserymen, Kelso, when they awarded a handsome gold medal to the one of their customers who sent them the heaviest and biggest Gooseberry. The firm, who make a speciality of Gooseberries, invited their customers to forward the largest berries they had, a large and highly successful exhibition being the result. The champion Gooseberry was a specimen of Ringer, a deep olive-green skinned variety, weighing 22 dwt. The grower was Mr. T. E. Middleton, Radcliffe-on-Trent. Numerous specimens, weighing 17 to 20 dwt., came from the well-known prize Gooseberry growers' districts in Lancashire and Cheshire, several from Yorkshire, Nottinghamshire, Staffordshire, and one from Macduff in the north of Scotland. The heaviest berries were Ringer, Bobby, London, Lord Derby, and Queen of Trumps. Growers complain that owing to the dryness of the season berries in size and quality are hardly up to the average this year.—("Kelso Mail.")

—— Renovating Herbaceous Beds.—Many plants have such a tendency to increase by suckers from the roots and form dense mats or clumps, that the soil is often overtaxed to supply sufficient nourishment. In most cases it is best to dig up the beds, divide and replant them, selecting the younger and healthy divisions. The writer has in mind, in this connection, instances of beds of Achillea millefolium rubrum, Aster tataricus, Helianthus Maximiliani and mollis. In some cases of the larger growing kinds it was found satisfactory, says "Meehan's Monthly," to hoe out the plants in 10 to 12 inch paths through the bed, early in the summer. This relieves the plants, and the growth generally will fill out in a short time, so that the mass effect will be undisturbed. The Sempervivum, or House-leek, is a frequent example of this overcrowding. Each mature plant produces several offsets on comparatively short stems each season. As these offsets mature and develop their offsets, all parts being thick and fleshy, there is but one natural consequence. Replanting of these may be done at any time, using large or small shoots. Although having little root, the succulent leaves and stems make the transplanting perfectly sure. Thinning them out will, in most cases, answer as well as taking up the bed.

—— Securing Fruit.—I read with much interest your article on "Fruit Growing and Selling," page 164, but, to my mind, such a season as the present, of far greater importance would it be to tell your readers how to secure a crop of fruit. Personally, I am only an amateur with a comparatively small walled-in town garden, but I have within the past few months been about pretty much, not only in Ireland, but in England, and my position of almost fruitless Pears, Plums, Cherries, Nectarines, and Apricots in the open air is almost the rule wherever I went in some of the best managed gardens in Great Britain. I and many others would therefore thank you or any of your numerous readers and correspondents who could give any practical hints for securing better crops. It is not the soil, for other years my trees had heavy crops. It is not the varieties, for I have about twenty varieties of Pears, and a dozen of Plums, equally deficient, and so of Cherries. I can hardly admit it is mismanagement, for I have had good crops other years, as already stated, but I am always glad to learn. I cannot say precisely what the immediate cause of failure has been this year, but I think here there have been two main causes, if not more. 1, Root drought and imperfect nutrition last year; and 2, an unfortunate spell of frost at night, just as most of the aforesaid fruit trees were in blossom, with the result of destruction of the organs of fructification.—W. J. Murphy, *Clonmel*.

— Carriage of Produce.—Speaking at the annual meeting of the Great Eastern Railway Company, Colonel Makins, deputy chairman, said, in the course of the proceedings, that the box system for placing consumers in direct communication with the small producers of fruit, vegetables, flowers, poultry, eggs, and minor products of the farm generally, was succeeding very well. The amount of money it yields directly is comparatively small, not exceeding at present £2000; but it has the great advantage of attracting from London direct to the pockets of the small farmers and market gardeners, allotment holders, and cottagers in East Anglia a considerable sum of money. The average value of the contents of each box is about 7s. 6d., and as the number of boxes carried during the year 1896 was 60,034, the aggregate value of the produce sent to the metropolis under the box system was £22,500. During the first half of the current year the number of boxes of produce sent over the system was 55,159.

— Flora of Santa Clara.—The flora of this province of Cuba was recently dealt with in a paper contributed by Mr. Robert Combs to a recent meeting of the St. Louis Academy of Science. The author described the results of his explorations, extending from the commencement of the rainy season of one year until the close of the dry season the following spring, the territory covered lying between the entrance of the bay of Cienfugos, on the south coast of Cuba, up the bay and the river Damuji to Rodas, and extending back from the river to Yaguaramos, and almost to the Cienega de Zapato, a region including nearly all kinds of soil and condition found upon the island, except those of the mountain regions and the mud swamps. A brief statement was made concerning the origin of the Cuban flora and its affinities with that of continental Central America, rather than the geographically nearer Florida region. The paper, says a contemporary, comprised a full catalogue of the collections made, which had been determined at the herbarium of Harvard University, and of which several sets had been distributed to the larger herbaria.

— Spraying Potatoes.—During the past fortnight many fields of Potatoes have shown unmistakeable signs of blight, by the spotting of the leaves and the peculiar odour always present when attacked by this insidious disease. There has seldom been a year when timely warning was so strikingly given as the present, the earlier sorts in gardens having been severely hit as early as the 1st July; and although the later varieties remained perfectly healthy for several weeks after, it was hardly to be expected but that they also would be attacked when they reached the same stage. That was the time to spray, as prevention is better than cure; and many fields have been saved by growers having profited by this timely warning and sprayed extensively, large growers using the horse machine, and still keep going on. It is not too late to save a considerable portion of the crop by careful spraying on those fields where the disease has not caught hold of the stem, although it may be perfectly distinct on the foliage. In Yorkshire and the great Potato growing districts of the south-east coast of Scotland—about Dunbar, notably—spraying has been largely carried out—in face of the adverse decision of the Highland Society; and many fields, strongly touched, have been brought back to a healthy condition.—("Irish Farmers' Gazette.")

— Fertilisers and Feeding-stuffs Act, 1893.—The Board of Agriculture has issued a leaflet giving publicity to the provisions of the Fertilisers and Feeding-stuffs Act, which came into force on and after January 1st, 1894. The provisions of the Act, which applies to wholesale as well as retail sales, may be classified as follows:—1, Provisions relating to the warranty to be implied on the sale of a fertiliser or feeding-stuff; 2, Provisions relating to taking samples and obtaining analyses; and 3, Provisions relating to offences, penalties, and legal proceedings. *Provisions relating to the Warranty to be implied on the Sale of a Fertiliser or Feeding-stuff.*—Every person who sells a fertiliser —*i.e.*, any article sold as a fertiliser of the soil—which has been manufactured or subjected to any artificial process in the United Kingdom, or imported from abroad, is required to give to the purchaser an invoice stating the name of the fertiliser, and whether it is artificially compounded or not, and what is, at least, the percentage of the nitrogen, phosphates soluble and insoluble—*i.e.*, in water—and potash, if any contained in the fertiliser, and this invoice is to have effect as a warranty by the seller of the statements contained therein. This provision does not apply to a sale where the whole amount sold at the same time weighs less than half a hundredweight. The fuller details are comprised in a leaflet, to be had, free of charge, from the Secretary of the Board of Agriculture, 4, Whitehall Place, S.W.

— Exacum macranthum.—Mr. W. Watson, in the "Garden and Forest," says, "For many years this beautiful tropical Gentianad has been successfully cultivated at Kew, but it has not yet become a popular garden plant, although several market growers near London have essayed its cultivation. It has numerous erect stems, from 1 to 2 feet high, clothed with rich green elliptic-lanceolate leaves 3 inches long and bearing terminal many-flowered corymbs of rotate deep blue flowers nearly 2 inches across. It is a biennial and requires the conditions of an intermediate house. This year the plants at Kew are exceptionally vigorous, and this is due to their having been planted out in beds of loam in the newly erected Mexican house. I have also seen beautiful pot specimens grown along with Begonias. The plant is a native of Ceylon, where it is said to be common up to 5000 feet elevation. It is the only one of the twenty species known that possesses any merit as a garden plant."

— Wireworms.—The Zoologist of the Royal Agricultural Society has been engaged in conducting a series of "pot experiments" to ascertain the efficacy of "mustard dross" as an antidote to wireworms, and has arrived at the following general conclusions:—(1) The dross is obnoxious to the wireworms, and fatal to them if they remain in it; (2) sown with the seed it keeps off the worm in the earliest and most vulnerable stage of the plant's growth; (3) if used too plentifully it delays the germination of the seed, but there would be no likelihood of this with the quantities which the cultivator would probably use; (4) experiments on the small scale do not indicate that it would be of any use as a top-dressing when the crop is up, as it has a burning effect on the plants themselves; (5) it seems eminently likely to be useful, if drilled with the seed, in cases where wireworm is to be anticipated, as after grass or Clover in land much subject to wireworm; (6) it is very light, and would have to be mixed with ashes or drilled on a calm day; (7) quantities equivalent to 2½ cwt. per acre have given distinctly beneficial results in the pot experiments.

— American Peaches.—The Maryland Peach crop, especially that on the eastern shore, was seriously injured by a frost on the 20th of April, which killed a large portion of the fruit buds in the tidewater section of the State. But it is true also that the curculio has done an uncommon amount of injury, as the great number of specked Peaches in the New York market indicates. Peach growers have never felt the necessity of combating the curculio, as Plum growers are compelled to do. And certainly they have not yet taken ordinary precautions against this danger. Last year, says an American contemporary, the Peach crop was unusually large, and the overloaded trees produced much small and inferior fruit, which was allowed to remain in the orchard. This gave the curculio an unusual opportunity, and Professor W. G. Johnson, the State entomologist, suggested to the growers last autumn that it would be wise policy to destroy as many of the small Peaches as possible, so as to prevent the larvæ of the curculio from entering the ground for pupation. There is no doubt that if this had been done the crop would have been less seriously injured. The fact that Professor Johnson predicted this danger ought to lead Peach growers to listen more carefully to expert counsel in the future.

— A Beautiful Cemetery.—The pretty little cemetery at Harton is now looking its best, and every evening during the past month the grounds have been crowded with visitors, who have not been backward in expressing their appreciation and admiration of the happy results achieved by the superintendent, Mr. B. Cowan. It is barely seven years since the cemetery was opened, and the transformation brought about is really wonderful. During that short space of time the trees have grown prodigiously. There is not a weed to be seen anywhere, the paths are the picture of tidiness, and the whole place gives evidence of the amount of care bestowed upon its welfare. The collection of alpine and herbaceous plants is considered by connoisseurs to be one of the best in the district, while the display of East Lothian Stocks is very fine. The carpet bedding has never looked better; the summer bedding is beautiful; and the likeness of her Majesty designed on a carpet bed is a strong feature of the place. It is an artistic combination of hardy dwarf plants, shaded to show a very pleasing contour of the face; it is easily perceptible, and has attracted during the summer thousands of admirers. To the ordinary visitor the place has more the appearance of a gentleman's private park in design, the trees being so arranged round the burial plots as to shut out the sight of the graves. Mr. Cowan's arrangements, from an educational point of view, must be of immense advantage, for every tree, plant, shrub, and flower is correctly labelled in English and Latin.—("Newcastle Daily Chronicle.")

HARDY FLOWER NOTES.

Autumn is with us as we write—a time of grain and fruit and flowers—Dame Nature's season of bounty. In the fields the ripe corn is falling before the reaper. In the orchards the Apples wax ruddy in the autumn sun. In the gardens we rejoice in the colouring of the showy flowers of the time. We need this bright colouring now. The leaves have put off the bright green of their youth, and have assumed a deeper tint; a more sober hue. Many of our flowers have gone, but welcome successors have come. We miss the flowers which, from their supporting arch behind the house, reminded us of the passage in "The Garden That I Love," in which the Poet Laureate tells us:—

> "Those clustering Roses fancy hath baptised
> Maids-of-the-Village; and adown they hang,
> Like to a waterfall you see far off,
> That foams, but moves not."

Its "daily litter of fallen petals" has ceased, and we have lost its beauty for the year. Other and more frequent-flowering Roses we have still, but the "Maids-of-the-Village" will smile upon the year no more. The Ayrshire Roses on the house front are over, too, but from among their leaves the deep purple flowers of Jackman's Clematis present themselves—scentless, but beautiful companions. The Delphiniums are over for the time, but the Phloxes delight us with their bright flowers. Some of the Sea Hollies are past their best, but Eryngium planum stands conspicuous in the border pleasing all with its blue-tinted globes and stems.

The Orange Lilies no longer show us that the perennial Sunflowers cannot rival the depth of their colouring, but the Tiger Lilies proclaim a combination the Helianthuses do not possess. Dahlias are aglow; needing all the rich variety shown by the autumnal annuals to counterbalance the effect of their formal globes or pointed petals. Besides the Tiger Lilies there are not many other bulbous plants yet in bloom. Chief among them is the Gladiolus, although, strictly speaking, its root-stock is not a bulb but a corm. Is there any flower more beautiful in its season? Does any other flower owe more to the hybridiser's art? As we look upon those stately spikes with their noble flowers of the most exquisite colours, shades, and markings we are more than pleased—are delighted—with the combination of beauties they give.

Veronicas with flowers of blue, purple, white or pink raise their clustered spires among the other border flowers, and the Sweet Peas—dwarfer than usual this year—please us with their sweet-odoured bright or soft tinted blooms. Tall Globe Thistles lure to their pearly-white balls the honey and humble bee.

Yet with all this variety there is a warning signal upraised. It comes from the earlier Starworts or perennial Asters whose first blooms give us a feeling of regret. They tell us of the wane of the days, though even now the little Anomatheca or Lapeyrousia cruenta displays its carmine flowers with their blood red spots not far away, as if telling us to beware of dwelling too long upon those premonitors of decay.

These Asters have some allies less known and comparatively little seen. Some of these are almost or quite worthless in the garden, and others have merits which give them value. Among the latter is Boltonia asteroides of L'Heritier, a plant of rather tall, but not ungainly, growth. Works of reference tell us that it was introduced in 1758, and that it comes from North America—a vague localisation, which, unfortunately, I cannot make more definite. In this light soil Boltonia asteroides grows about 4½ feet high, but this height is exceeded in some gardens. I cannot say that I regret this shortcoming in height, as it is unaccompanied by any loss of beauty. Unless "cabin'd, cribb'd, confined" by undue tying this Boltonia is a rather elegant plant. The entire, lanceolate leaves are of a pretty shade of green, and the plant possesses a light and informal appearance. This is heightened by the character of the flowers, which are what is called "flesh-coloured," and are freely produced in a panicle.

It is one of the numerous Daisy-like autumn flowers so plentiful later on, but not as yet so numerous as to make it unwelcome. B. asteroides is readily increased by division in spring or autumn, and will grow well in almost any soil or position. It appears to take kindly to a little shade, and its flowering is thus prolonged.

Among the Bellflowers now in bloom are two of the Symphyandras. These are allied to the Campanulas, but differ from the true Bellflowers by their anthers being connate. S. pendula, which grows freely on the rockwork here, is a troublesome plant with many. It thrives well with a little shade, and, although not showy, is generally appreciated. It is a true perennial in my garden. Another species grown for some years is S. Hoffmanni, a native of Bosnia. So far as my observation goes this is of biennial habit, but it produces and ripens seed so freely that there is never any want of self-sown seedlings to keep up the succession. I have met with it under the name of S. Kaufmanni, but this is an obvious error, and the name of Hofmanni is that recognised at Kew. Like S. pendula, it is not a showy plant. It is of erect habit, and here only grows about 1 foot high. It forms a neat, bushy plant, producing a considerable number of drooping, white, rather funnel-shaped flowers. It can be raised from seed, which is obtainable from some seedsmen.

On former occasions I have referred to Olearia stellulata, the Starry Daisy Bush. Less seldom seen, although scarcely so pretty, is O. Haasti, which forms a desirable dwarf shrub for the rock-garden or border. Haast's Daisy Bush comes into bloom later than the Starry one, and looks very different with its glossy leaves with whitish under surfaces, and its smaller flowers. It is hardier than O. stellulata, and forms a very neat bush, freely covered in the end of July and beginning of August with cymes of white flowers. It is not difficult to grow in light soil and with a south or west exposure, and is easily propagated from cuttings.

It is raining heavily as these lines are written, and the brilliance of the flowers is dimmed by the rain and chastened by the clouded skies. Yet these cannot deprive us of the pleasures of the flowers. The Montbretias, with their crimson or golden flowers, seem as oblivious of the unpropitious elements. The Water Lilies on the pool are nearly all closed, but a flower of Nymphæa carnea is open far enough to show its exquisite colouring. With the flowers mentioned before, and with others which are in bloom, we can content ourselves till the dark clouds roll away and the sun comes out to give fresh beauty to the flowers and new pleasure to their owner.—S. Arnott.

EXHIBITING GRAPES—The SPLICING SYSTEM.

Various methods are resorted to in growing Grapes, in these days of keen rivalry, with the object of producing the best and most imposing results. There is the extension system, the spur system, the grafting system, the express system, but there is nothing like the splicing system for producing "big" bunches quickly. Talk about the decadence of gardening, your "Traveller" is quite behind the times. We have in these days youths so ardent that they can do in an hour or two what the "old" gardeners took years to accomplish—*i.e.*, get a first prize card attached to their exhibits at a great national show, but only by recourse to this system. This feat was accomplished last week at the Crystal Palace, and in a manner that surpassed most previous efforts. The artist, however, unlike most artists who accomplish something out of the ordinary way, did not seem anxious to receive credit for his skill. He not only made no complaint about his work being imperfectly displayed, but his modesty was so great as to impel him to hide it. Its true character had to be "dragged out," so to say, and so far as can be learned the honour of the discovery rests with Mr. James Hudson of Gunnersbury.

Mr. Hudson is a very observant man, and if he find anything unusual he generally also finds a way of getting to the bottom of it. During a quiet stroll round, and with more time at his disposal than the judges had, he observed a barrel-shaped bunch of Grapes in the Palace Show. This striking him as abnormal, his curiosity was so far incited as to tempt him to look behind the curtain. This was formed of a little wadding for the preservation of the stem of the bunch, and a covering of tissue paper for the sake of appearance.

Drawing aside the curtain with a tenderness that may be imagined, he found the stem well secured to the stand—a bit of thoroughly good workmanship in that respect. There was no loose looping about it, such as a coil or two of tape, but it was more after the binding of the handle of a cricket bat or a fractured limb. It almost suggested, in fact, that the operator might have been attending ambulance classes conducted under the auspices of some technical education committee.

But the bandages did not look quite right to the inspector, and he seems to have fingered them till he found an "end." Pursuing his investigations he discovered another, and still another. These proved to be the stalk ends of "shoulders," which in the course of nature had issued from other bunches of Grapes, and hence, from the operator's point of view, had grown in the wrong place. A transference was therefore effected, with the result that the bunches on the Vines were made smaller, while those off them, and for the "boards" were made larger. One little addition appeared to suffice for one bunch, but another needed two, and a third even three, extra shoulders to give it the desired size. The judges, upright honourable men, thinking no evil, and pressed for time, attached to the collection which contained these imposing Grapes the "first prize."

So well had the splicing been accomplished that even the exhibitor of the collection did not discover what his young man had done till the mechanism was pointed out to him in the show the next morning. He was naturally much annoyed. If all had gone well with the Grapes he would, no doubt, have found out the handiwork on their arrival home, when, it may be expected, he would have returned the prize, which, under the circumstances, he did not receive.

Such instances as this are rare. It is a case of zeal overcoming discretion, and it is hoped that the ardent youth will have gained a lesson that will deter him from again indulging in the splicing system for the quick production of barrelled shaped bunches of prize Grapes.—On-looker.

SEASONABLE HINTS ON FLORISTS' FLOWERS.

As the summer draws towards its close, and the shortening days tell us that autumn is upon us, there are many things which call for the gardener's thought and care, no matter what may be the special portion of horticulture to which he directs his attention. Some are now thinking about bulbs—what blanks have been made, and what bulbs will be required to make up the deficiency; others are bent upon propagating, and are cutting their "Geraniums" and other plants, so as to have them ready for the ensuing spring; but perhaps no one is more deeply interested than the grower of what are popularly known as florists' flowers, nor does it at all follow that the directions for one season are applicable to another. The weather changes so much in our fickle climate, that the conditions of the plants and the operations necessary for keeping them in good health vary from year to year.

We have no doubt had a very strange season, the cold drying winds of May and the drought time which we have experienced have told upon some plants, but as the flowers of which I write are mostly grown under protection many of these adverse circumstances can be guarded against; the plants can be protected from rough winds and drenching rains, and without being coddled can be preserved from evil influences. As in duty bound, whether as regards alphabetical order or the charms it exercises over those who grow it, I take first

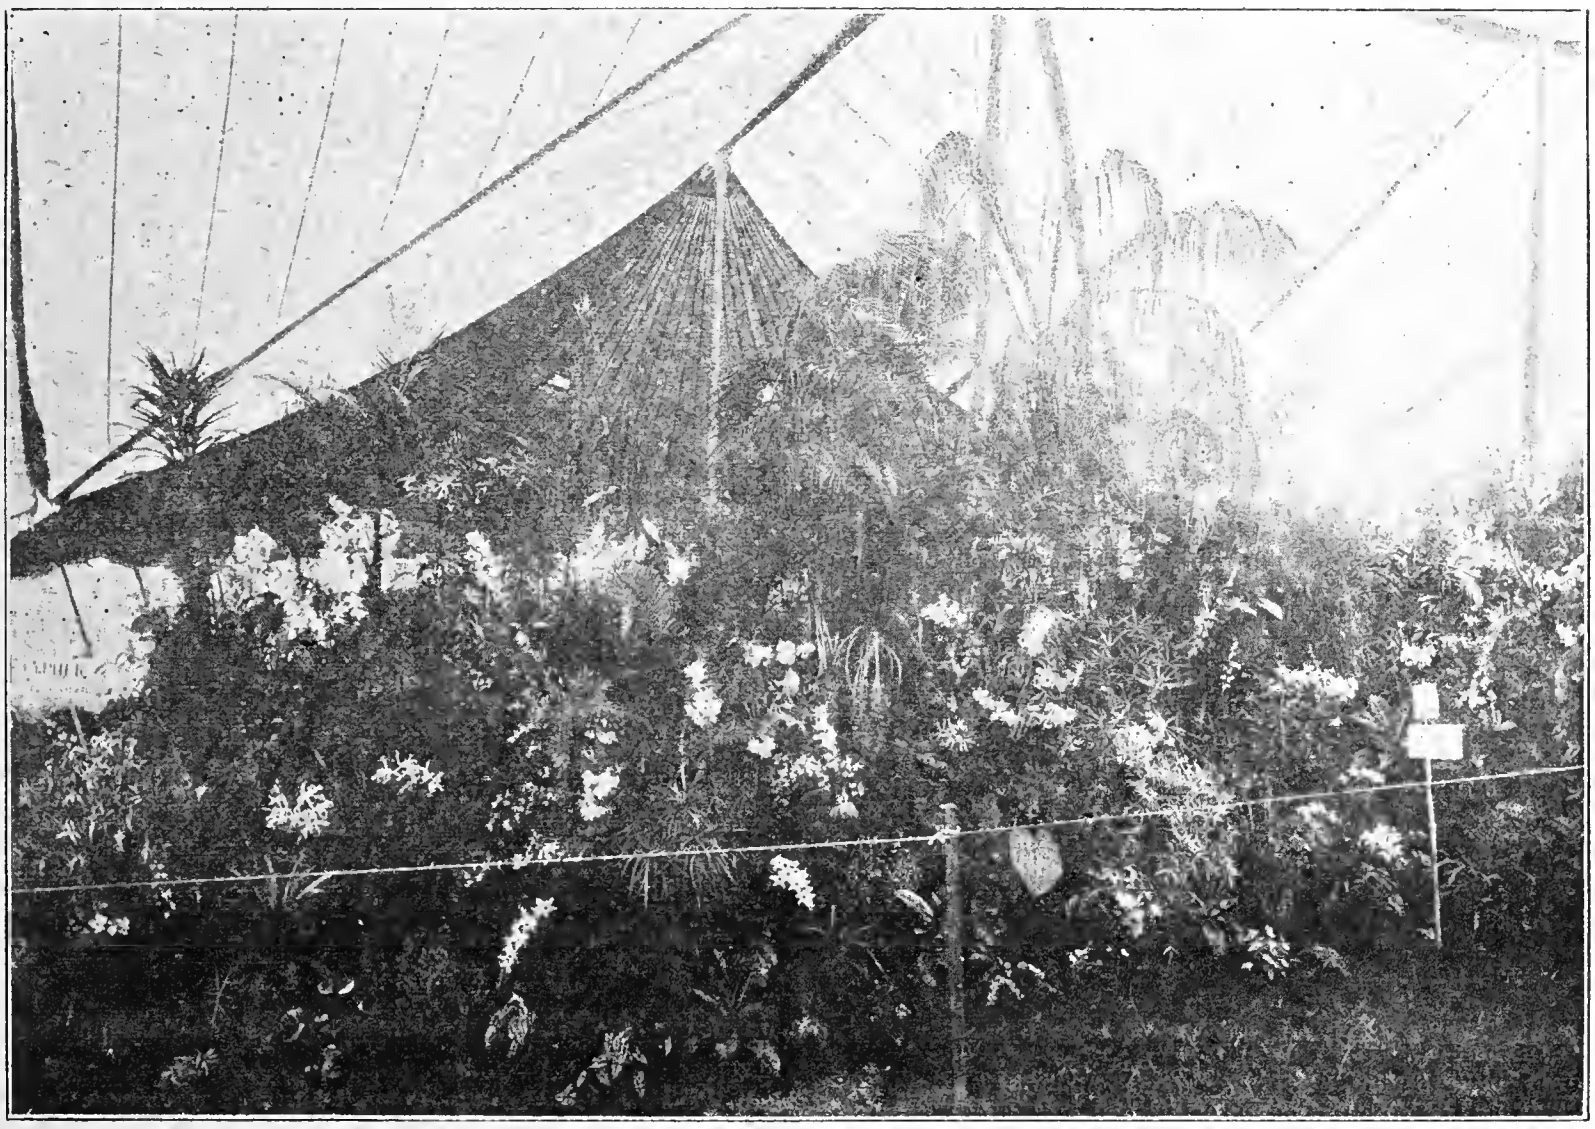

FIG. 27.—MR. J. CYPHER'S GROUP OF PLANTS. (*See page* 188.)

THE AURICULA.

I think, upon the whole, the summer has been favourable for these plants; it is true we have had some hot days, but the hot weather has not been continuous, and consequently I think the plants, at least as far as my own are concerned, look very well, are free from aphis, and few of them have perished during the summer, as they often do. It will be necessary soon to see that they are placed in their winter quarters; some have houses, other frames, and others pits in which to keep them. Wherever they are placed care must be taken that the lights are sound and free from drip. The Auricula will stand a good deal even of frost, provided the soil is dry, and nothing is so injurious to them as a drip, and, of course, if frost enters the place where they are housed it lays hold much sooner of a sodden soil.

The plants ought now to be carefully looked over, all dead foliage removed, and the plants brushed with a camel's-hair pencil if there be any signs of aphis; but when they are housed in their winter quarters it would be well to give them fumigations, so as to kill any that might be left. I do not think we need be so much afraid of the woolly aphis, which gave us such a scare a few years ago; in fact, I take little notice of it now, except it be round the collar of the plant, whence I am careful to remove it. I used at one time to take it away from the fleshy roots by turning the pot upside down on the hand; but this I have long since ceased to do, and I do not find that the plants show any sickly appearance. It used to be said that they turned their heads on one side, as if they were suffering; but I do not see this even in plants which are very full of it. I have, therefore, of late contented myself with getting as free of it as I can at the potting time, and not troubling myself afterwards.

The Auricula in one respect is unique; while other florists' flowers increase their numbers of varieties yearly, it is only now and then that an Auricula comes into commerce of sufficient merit to replace the older kinds, and so if one is asked, "What variety shall I add to my collection?" it is very difficult to name any. Thus if we take green-edged, perhaps the following may be regarded the best grown, bearing in mind that it is always a very limited class:—Prince of Greens, Rev. F. D. Horner, and Colonel Taylor, to which perhaps may be added Abbé Lizst, raised by Mr. James Douglas, although this is at present expensive. Monarch I thought would have taken a leading position, but it has deteriorated since it was exhibited as a seedling. Two of these are poor growers, Prince of Greens and Colonel Taylor, the most useful of the section being undoubtedly Rev. F. D. Horner. When we come to grey-edges there is a greater choice, and although George Lightbody was raised many years ago by Mr. Headly of Cambridge, there is not one variety raised since which can compare with it. Richard Headly, Lancashire's Hero, George Rudd, Conservative, and Traill's Beauty (sometimes), are all good and useful flowers. Then in white edges we have Acme, Heep's Smiling Beauty, Mrs. Dodwell, and John Simonite, the last scarce and difficult to grow. Selfs.—A more prolific class than any other, and if seed be sown a greater number of seedlings may be selfs, although the seed may have been saved from edged flowers, yet after all very few first-rate kinds have been added of late years; Heroine, Mrs. Potts, Black Bess, and Sapphire being, however, all first-rate varieties. Of the older ones Lord of Lorne, C. J. Perry, Mrs. Douglas, and Mrs. Sturrock are serviceable both for exhibition and stage.

This will now be a good time to add to the collection any varieties that may be desired, as they need not be sent in pots, but if turned out and put into paper envelopes without disturbing the soil and potted on arrival, will have time to recover themselves before the winter begins. I have said nothing about the Alpine section because I do not grow them. There are some very handsome flowers amongst them, but somehow or other I never took to them, and "I am too old a dog to learn new tricks." And so with regard to Fancies, I was very much taken with some that I saw exhibited at the Drill Hall last spring, and almost decided to have some, but on thinking it over my conservative instincts were too strong,

and I came to the conclusion it was better to continue the old ways and not have anything to do with them, however varied and pretty they might be.

Carnations and Picotees.

The exertions of Mr. Martin R. Smith have led to a great change in the cultivation of these plants. The success of his cross fertilisation has been very manifest. Though it has somewhat tended to lessen the estimation in which the old florist varieties were held, they have never lost their charm to me, although I quite agree that as far as the decoration of the garden is concerned these new and varied forms with their wonderful shades of colouring are more effective. The autumn of 1896 was an unfavourable one for them, and it was difficult to obtain good layers. Many, perhaps, are independent of these and raise their seedlings year by year, while others have probably by this time completed their layering. As soon as they are rooted they should be potted off, if possible, singly in small pots, so as to be ready to put in the frames for the winter, for I do not advocate the plan of planting them out in the autumn. It may succeed, but a severe or very wet winter is likely to do them much injury. and I would always advise they should be kept under cover for the winter. One of the most remarkable things about the new race is the number of yellow varieties which are produced. Formerly we had only two or three worth growing, but now with every collection of seedlings we get some. Since the rains which we have lately had I find the grass much better fitted for layering ; it was very harsh and wiry before, but it is now soft and pliable, and I do not think any time has been lost by putting the operation off.

Gladiolus.

There is not much to be done now beyond securing the blooms and enjoying their beauty, but those who wish to grow from seeds should take the opportunity of cross fertilising the blooms, selecting for that purpose the best flowers that they have, but also those that form the greatest contrast. There is no flower more easy to hybridise, and I may add there is no flower the humble bee delights more in rolling in, therefore a careful hybridiser will strive to be beforehand with him. At the same time he must remember that some of the finest flowers that we have have come from natural and not artificial fertilisation. On the whole I think the season has been a favourable one for these flowers.

Pansies.

The droughty seasons which we have lately experienced in the south have not been favourable to the growth of these plants, for they much delight in moisture and cloudy skies. The few that I can grow are in pots ; the plants have been cut down, and have now to be divided and placed in small pots for the winter. I know that it will be said this is a lazy plan, and I plead guilty to the charge ; but then I do not grow for exhibition, nor can I house a large number, so that this is sufficient for my wants.

Roses.

I think that it is a very good plan, instead of leaving all the pruning for the spring, to cut out those growths which have flowered, and from which nothing is to be expected next year, as it gives freer scope for light and air, and the plants are not so liable to be injured by high winds, and for this reason very long shoots ought to be partially shortened and have a stake put to them.—D., *Deal.*

IXORA NOTES.

Few stove plants are more valuable both for exhibition and decorative purposes than Ixoras. As large specimens with rich deep green foliage and noble heads of flowers they have an imposing effect, while as smaller plants with from one to half a dozen trusses few plants can excel them during their period of flowering. Ixoras are purely tropical plants, and the imported species are almost exclusively from tropical Asia. An Asiatic name has, therefore, been appropriately given to the genus, Ixora being a Malabar idol, to which the flowers of Ixora stricta (as it was originally named, but now known as coccinea) are offered by the natives.

Ixoras can be easily propagated by cuttings. Take a short-jointed half-ripened cutting about 6 inches long and insert it firmly in a small thumb pot in a compost of peat, leaf soil, a little fibrous loam, and a good admixture of silver sand. Plunge the cutting pots in bottom heat in a moist well-heated stove or propagating house, and not many days will elapse before roots are emitted. When these reach the sides of the pots transfer them to pots a little larger, and eventually into 5-inch pots, using the same sort of soil as described for the cuttings. Healthy plants in 5-inch pots are of great use for table decoration while medium-sized plants with six or seven trusses of flowers on them are very valuable for many purposes of decoration. The next shift should be into a 6-inch pot. Future shifts must be at the discretion of the grower, according to what size plants are required, but large shifts should never be given, which often result in sour soil and unhealthy plants. A little liquid manure may be given occasionally when the plants are established. Do not give the plants too much water in the winter time, and avoid drip from the roof, which is fatal to good foliage. During the growing season afford plenty of heat and syringe twice a day, the pots if possible being half plunged in a hotbed. Any shoots threatening to steal strength from the others should also be stopped to give two or three shoots instead of one. If fly, or thrips, or mealy bug appear there must be smoking and sponging at once.

This treatment should continue, with a little shade from very bright sun, until September. The pots should then be raised out of the hotbed, the plants placed near the glass and in full light ; and though syringing may be resorted to at times, it should gradually be discontinued, and water at the roots also lessened, but never so as to cause the plants to flag. The object is to ripen the shoots formed. During October and November the water must be lessened, and the temperature may fall then and on to February to 60° and 55°, the roots just kept healthy and no more, and care taken of the leaves by syringing and sponging on a fine bright day. The rest is thus given at the dull season, as the flowers are much more pale when produced in winter. About March, or earlier, the plants may be moved into a higher temperature by degrees, and at first the pots partially and ultimately three-parts plunged in a sweet hotbed, with openings below the pot to secure drainage. The temperature may be gradually raised to 75° and 80° with air, and of course waterings at the root will be more needed as the temperature rises, and the syringe must be pretty well used before the bloom trusses show. Then a drier atmosphere should be given and the plants be lifted out of the bed as the flowers open and kept cooler and drier to preserve the bloom.

Ixoras cannot be grown in a low temperature. On this point a good authority has written as follows :—"I would particularly allude to this high temperature and moist atmosphere in summer as essential to success, as I have had several complaints that the Ixoras cannot be managed in a warm greenhouse temperature—about 50° in winter, and very airy in summer. It is waste of time attempting such plants under such circumstances. I have given them up for a time because I have not enough heat for them. Those who can command a rather dry atmosphere of from 55° to 65° in winter and a fermenting bed in spring and summer, securing a bottom heat of from 80° to 85° and 90°, and a top temperature of from 70° to 85°, and 5° to 10° more in sunshine, with abundance of atmospheric moisture, will no doubt succeed with these lovely plants, which are well deserving all such attention."—L.

ISLE OF WIGHT.

The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Ventnor on August 7th. Dr. Groves presided over a fair attendance of members and friends. Mr. C. Orchard, F.R.H.S., read an excellent paper on "The Progress of Horticulture in England During her Majesty's Reign." The subsequent discussion proved interesting and profitable. Mr. W. W. Sheath, Macrocarpa Gardens, Ventnor, was awarded the Association certificate for an excellent group of miscellaneous plants. Ten new members were enrolled.

Shanklin.

The eighteenth annual summer Show of the Shanklin Horticultural Society was held by permission of Mr. Spartali in the beautiful grounds of Rylstone, which overlook the far-famed Shanklin Chine, on August 18th. The quantity and quality of exhibits exceeded and surpassed those of any previous year. The meteorological conditions were favourable, and the attendance was very large. This is unquestionably the largest and best Show in the Garden Isle. The Judges had a difficult task to perform, the competition being very keen. Dr. Dobbs judged the honey, and expressed a wish that it were possible to give every exhibitor a prize, as all were really worthy of something. There was an excellent show of Lord Suffield Apples. The Shanklin Society again won the sash and counties' championship, offered by Messrs. Cannell, for an exhibit of fruit, flowers, and vegetables.

Mr. W. H. Geddes secured the I.W. Horticultural Improvement Association certificate for a good collection of Sweet Peas. The floral decorations were very fine. The principal exhibitors at the Show were Messrs. F. A. Hill, S. Banks, A. Richards, C. H. Snook, W. A. Kent, F. Bastiani, B. Roach, G. H. Kent, and G. Witty.

Niton.

The third annual summer Show of the Niton Society was held on August 18th, in the charming grounds of The Orchard, by permission of Lady Mary Gordon. Many of the exhibits staged showed high-class culture. The I.W. Horticultural Improvement Association certificate was awarded to Mr. H. Jacobs for a collection of vegetables. The principal exhibitors were Messrs. G. W. Creeth, W. Cotton, H. Jacobs, A. Humber, F. Niblett, A. Salter, C. Long, W. Hayles, and J. Niblett.

Freshwater.

This show was held on August 18th in Farringford Park by permission of Lord Tennyson. The exhibits were not so numerous as in previous years ; but all round the standard of excellence had improved, and with care in staging and labelling the Show could be made still more interesting and profitable to those attending. The I.W. Horticultural Improvement Association's certificate was awarded Mr. A. W. Kime, F.R.H.S., gardener to Colonel Crozier, J.P., Westhill, Freshwater, for three bunches of Grapes. Amongst the principal exhibitors were Messrs. J. Martin, F. Banham, B. Grist, W. Morey, J. Covey, H. Fry, G. Wheeler, J. Collis, and W. Stephens. The bee tent proved a great acquisition to the Show, and much interest was taken in the lectures and practical demonstrations conducted by the Rev. Mr. Medlicott, Swanmore Vicarage, Bishop's Waltham, and his assistants. It is certainly greatly to be regretted that in a small place like the Isle of Wight there should be three shows held on the same day. It is to be hoped that next year this will be avoided. - S. H.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—AUGUST 24TH.

THE meeting at the Drill Hall on the above date was a very small one indeed, neither the floral, Orchid, nor the fruit section being largely represented. The superb spike of Grammatophyllum from Burford Lodge attracted almost as much attention as the remainder of the exhibits put together.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Messrs. G. Bunyard, J. H. Veitch, A. F. Barron, W. Pope, A. H. Pearson, A. Dean, G. Miles, H. Balderson, G. Norman, R. Fife, and F. Q. Lane.

Mr. O. Thomas, Royal Gardens, Frogmore, staged a handsome new seedling Melon, which resulted from a cross between Duchess and Beechwood. It was named Frogmore Scarlet. It resembles the old Beechwood somewhat closely. Mr. Corbett, gardener to the Rev. Marquis of Normanby, Mulgrave Castle, staged Tomatoes Mulgrave Castle and Royal Sovereign. Mr. J. McIndoe, gardener to Sir J. W. Pease, Hutton Hall, Guisborough, sent Japanese Plum Burbank; and Mr. W. Kemp, Barnes, Cucumber Covent Garden Favourite.

Upwards of two dozen fruits of Melon Middlesex Hero were exhibited by Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, who also showed a new variety named Thames Bank. Mr. J. Robinson, gardener to W. Lawrence, Esq., Elsfield House, Hollingbourne, arranged a collection of vegetables, comprising highly creditable examples of Onions, Savoys, Carrots, Tomatoes, Potatoes, Beet, Cabbages and Beans (silver Banksian medal).

Mr. A. H. Rickwood, gardener to the Dowager Lady Freake, Fulwell Park, was represented by a good collection of fruits. Amongst others were noticed Peaches Goshawk, Grosse Mignonne, Early Louise, Barrington, Dr. Hogg, and Hale's Early; Apples Lord Suffield, Lord Grosvenor, and Keswick Codlin, with Plums, Morello Cherries, Currants, Pears, and three bunches of Black Hamburgh Grapes (silver Banksian medal).

Messrs. G. Bunyard & Co., Maidstone, sent a large collection of Nuts, comprising twenty dishes of obs and Filberts. There were, besides others, Garibaldi, Dawson's Prolific, Géant des Halles, Cosford, Bergeri. White Filbert, Webb's Prize ob, Purple Filbert, Kent Cob, Atlas, and Frizzled Prolific Filbert. Mr. G. Elliott, gardener to Captain McDonald, Hurst Side, West Molesey, exhibited fifteen bunches of Grapes, all in capital condition (silver Knightian medal). Messrs. T. Rivers & Son, Sawbridgeworth, sent boxes of Plum Monarch, Green Gages, Golden Transparent, and Late Transparent, with two bunches each of Gradiska and Directeur Tisserand Grapes.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair), with Messrs. O. Thomas, C. T. Druery, H. B. May, R. Dean, G. Stevens, J. F. McLeod, C. Jeffries, J. D. Pawle, J. Walker, G. Nicholson, J. Fraser, H. J. Jones, R. M. Hogg, and J. Fraser.

The most conspicuous exhibit in the floral section was an immense group of Caladiums arranged by Messrs. J. Laing & Sons, Forest Hill. The plants included well-grown examples of Michel Buchner, Louis Van Houtte, Baron Adolph de Rothschild, Flammant Rose, Princess of Teck, B. S. Williams, Ibis Rose, George Berger, and many others. The same firm also had a handsome exhibit of beautifully coloured Crotons (silver-gilt Flora medal).

Messrs. R. Wallace & Co., Colchester, exhibited a large collection of hardy flowers of fine quality. Liliums, Gladioli, Montbretias, Watsonia Ardernei, and many others (silver Flora medal). P. Purnell, Esq., Woodlands, Streatham, staged a group of miscellaneous foliage and flowering plants, comprising Ferns, Crotons, Hydrangeas, Begonias, Fuchsias, and others (silver Flora medal). Messrs. J. Veitch & Sons, Ltd., Chelsea, sent an interesting collection of Ericas, including E. vulgaris Alport, cinerea alba, vulgaris monstrosa, v. cuprea, v. florepleno, v. Hammondi, v. aurea, and others (silver Banksian medal).

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. De B. Crawshay, H. J. Chapman, W. H. White, J. T. Gabriel, W. H. Young, E. Hill, T. W. Bond, W. Cobb, A. H. Smee, A. Mason, and H. M. Pollett.

Messrs. F. Sander & Co., St. Albans, exhibited a few Orchids, comprising Lælio-Cattleya Sanderæ, L.-C. Rose Measures, Cattleya Gaskelliana, and one or two others. A silver Banksian medal was given to Messrs. J. Veitch & Sons, Ltd., for a small group, including several Cattleyas, Lælio-Cattleyas, and Cypripediums Janet and Melanthus. Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, sent Lælio-Cattleya Janet, Cymbidium species, and a spike of Grammatophyllum speciosum. For this plant the Orchid Committee gave a gold medal and a first-class certificate.

CERTIFICATES AND AWARDS OF MERIT.

Dahlia Marjorie (C. Turner).—The form of this Show Dahlia is excellent. The colour is yellowish buff, shaded with rose (award of merit).

Dahlia Hypatia (C. Turner).—If rather dull in colour this Pompon is of splendid shape. The shade is dull terra-cotta (award of merit).

Dahlia Vesta (C. Turner).—A pure white Pompon of good quality (award of merit).

Dahlia Phryne (C. Turner).—A charming Pompon of which the yellow petals are edged with bright red (award of merit).

Dahlia Night (J. Stredwick).—This is an intensely dark variety of good form (award of merit).

Dahlia Amber (J. Stredwick).—A beautiful variety of the Cactus section. The colour is yellow, the other petals being flushed with rose (award of merit).

Ficus radicans variegata (W. Bull).—A handsomely silver-variegated form of the type (first-class certificate).

Goodyera Rollisoni (W. Bull).—The foliage of this plant is very handsome. The central portion of the leaf is dull velvety green, and the edging is yellow (award of merit).

Grammatophyllum speciosum (W. H. White).—Flowering for the first time for upwards of forty years, the spike of this plant attracted attention from everyone. The spike is about 7 feet high and the flowers very numerous. The colour of the flowers is brown and gold (first-class certificate).

Lælio-Cattleya Andreana (H. J. Chapman).—A beautiful hybrid, with narrow white petals and sepals delicately flushed with rose. The lip is long, narrow, and of a rich maroon colour (award of merit).

Lælio-Cattleya Juno (N. C. Cookson). A lovely bigeneric hybrid. The sepals and petals are delicate rose, the former being delicately suffused with yellow at the tips. The lip is crimson purple (award of merit).

Melon Frogmore Scarlet (O. Thomas).—This Melon is not only handsome in appearance, but of splendid flavour. It has a great depth of luscious flesh (award of merit).

REMINISCENCES OF BODORGAN.

ON the main line from Chester to Holyhead, about fourteen miles distant from the latter station, lies the ancient village of Bodorgan, where we alighted on our way to visit the Welsh seat of Sir George Meyrick, Bart. On the high road leading from Bodorgan Station we called to inspect the ancient church of Llangadwaladr, the present vicar of which told us the structure was originally built in 508. Since then this ancient edifice has, however, been several times restored, and a few of the historic features carefully preserved, including a notably inscribed stone of the seventh century, as well as a beautiful seventeenth-century window, the rich colours in same being beautifully blended and striking in appearance.

The gardens, were, however, our *rendezvous*, and under the guidance of Mr. Gray, Sir George's head gardener, we hastened on over a distance of some two miles to what proved to be a veritable paradise. No less an area than 8 acres are devoted to the cultivation of flowers, fruits, and vegetables; and everywhere evidence of skilful and successful culture was to be seen. In the extensive vegetable quarters, which were clean and tidy throughout, we noticed, in addition to many of the old standard varieties, several novelties under trial, the rule evidently being to have the best of everything.

Summer bedding is not carried out on an extensive scale, owing to the bleak and exposed position of many of the flower beds, the majority of which were filled with a choice collection of dwarf Conifers, the appearance of these showing that the soil and situation suit their culture admirably.

Old-fashioned herbaceous flowers are, however, extensively grown, and we noticed with pleasure that an additional large border, running the whole length of the garden, had recently been planted with a choice collection of these from the famous nurseries at Chester. The garden walls are well covered with a general collection of hardy fruits, as well as some healthy-looking specimens of evergreen shrubs, including a particularly well-furnished example of the Maidenhair Tree (Salisburia adiantifolia). The glass houses, thirty in number, contain carefully selected collections of Orchids, Crotons, Coleus, Begonias, and other plants, including a large number of Adiantums, all in the picture of good health.

The vineries and Peach houses are, however, the chief attraction in the way of "glass," and these contained some beautifully finished bunches of Madresfield Court, Lady Downe's, and Muscat of Alexandria, several of which have since figured in the prize lists at Liverpool, Chester, and other shows. At the time of our visit a long range of Ewing's, now old-fashioned, wall glass protector was being converted into Peach houses, which will give Mr. Gray still further scope in this direction.

The pleasure grounds abound in fine collections of Cedars, Pines, evergreen and flowering shrubs, and nowhere have we seen any of these make such rapid growth as they do in this genial Anglesey soil. Particularly worthy of notice are the Araucarias, several of which have attained a large size, and are at present bearing cones. This is not altogether a rare occurrence here, as Mr. Gray pointed out, with some amount of pride, to several healthy young specimens which had been "bred and born" in these beautiful grounds. Fine examples of Photinia serrulata, Forsythia viridissima, Garrya elliptica, Weeping Hollies, and Rhododendrons, the latter showing enormous yearling growths, all call for special mention. Splendid deciduous trees are also plentiful, many of which, even to the Hawthorn, being thickly covered with long-bearded species of grey lichen, giving them a somewhat weird-looking appearance.

The mansion, which is approached by a carriage drive nearly a mile in length, is substantially built on an elevated spot overlooking Maltreath Bay, on the coast of the Irish Sea. The interior is furnished in excellent taste, and contains several valuable family paintings, by eminent artists, as well as ancient historic relics. From the terrace commanding views of Snowdon, Llanfairfechan, Carnarvon Bay, and other popular resorts in North Wales are to be seen, the whole outlook being one of striking grandeur.

A hurried visit to the seashore brought a most enjoyable and profitable day much too suddenly to a close; but pleasant reminiscences of this beautiful Anglesey home still linger with us.—GEORGE PAXTON.

MEDEA AND MARÉCHAL NIEL.

I AM gratified to find my estimate of Medea supported by such authorities as Mr. A. Piper and Mr. W. Easlea on page 151 of the *Journal of Horticulture*. Judging from what he says of it in his catalogue (in which he does not always follow the raisers' descriptions), Mr. Frank Cant, who grows it magnificently, has an equally high opinion of the value of this Rose. This rosarian describes it as follows, "Lemon yellow, with canary yellow centre; large, very double, and perfect globular form; a good grower and free bloomer; it promises to be first-class." And I think that the promise of what Mr. Cant writes at the end of his estimate has been amply redeemed. I recently showed a superb bloom of Medea to a successful cultivator of Maréchal Niel, and while he insisted on the greater depth of colour possessed by the queen of Noisettes, he admitted that Medea "had a more vigorous constitution; firmer and stronger petals, and greater substance."

It is, as "D., *Deal*," very clearly indicates, its delicacy of petal and peculiarly pendulous habit that impose on Maréchal Niel when grown in the open garden, its greatest limitations. I have invariably discovered that of all existing Roses of its special character it is the most susceptible to the influence of rain. Only in a very exceptional season is it capable of unfolding its marvellous capabilities. What "W. R. Raillem" has said regarding its so-called perpetuality is very interesting as indicating that, with adequate protection during the winter season and careful, judicious pruning, its period of bloom may be considerably prolonged. Nevertheless, I still venture to question if it can expressively be termed a perpetual bloomer, like Madame Hoste, Medea, or Marie Van Houtte.

Unlike Mr. A. Piper, I am disposed to give Medea a higher place in my estimation than Perle des Jardins. The latter is, of course, a deeper yellow, if that is any merit from an artistic point of view. For my own part I much prefer the complexion of Medea, deepening as it does from pale lemon in the outer petals to the richest canary yellow in the centre, with a most exquisite external suggestion of carmine. It has also a much finer form and habit than Perles des Jardins, and rarely appears, like that variety, with divided blooms.

In the special contribution which created this controversy I made no comparison of Medea with Maréchal Niel, no allusion whatever having been made to the latter variety, which I have never regarded, by reason of the limitations to which I have alluded, as adapted for the special purpose of garden cultivation.—DAVID R. WILLIAMSON.

NOTES FROM STONELEIGH ABBEY.

A RECENT call on Mr. H. T. Martin, who took charge of these gardens about six months ago, found him comfortably settled in his pleasant home among the sylvan scenes of "leafy Warwickshire." The garden is a good one, and has long been noted for the extensive and successful culture of fruit and vegetables. These things Mr. Martin continues to maintain in good condition, as well as to make steady improvements in other directions. Two new features introduced are a couple of hundred Chrysanthemums grown on the large bloom principle, and the modern method of growing Onions, a grand bed resulting. They were planted about a foot apart, and the large shapely bulbs show that their wants have been well attended to.

Now for a word about the Chrysanthemums. They are certainly the tallest plants that I have met with this season, and have evidently been grown throughout without a check. Both wood and leaves are wonderfully strong, yet apparently hard, and likely to ripen well. This will, of course, depend to a great extent upon the weather we experience from the present time till November. There is just a doubt in my mind as to their ripening properly, for the situation at Stoneleigh is not an ideal one for Chrysanthemum growing, lying somewhat too low to secure the necessary exposure. Of this, however, we may be certain, that Mr. Martin's past experience with "the queen of autumn flowers" will enable him to handle them in a skilful manner.

Vine-growing is at present conducted under considerable difficulties, but it is probable that in the near future matters may be improved by a re-arrangement of the borders, and the system of planting. A promising stock of decorative plants is being worked up, and I noticed among them some of the best varieties of Crotons and Draæenas, all looking clean, healthy, and colouring well. Gooseberries grown as cordons are one of the features of Stoneleigh, and are alone worth going a long journey to see; from top to bottom they are loaded with fruit, and I am told that the crop seldom if ever fails when grown on this system.

We should, no doubt, have spent much more time in examining various crops, debating methods of culture, and having generally a good time of it, but for the fact that we were reminded we had yet to partake of the cup of tea which Mrs. Martin had so thoughtfully provided. This and many other kindnesses we thoroughly enjoyed, and then set out for a pleasant homeward drive towards the stately towers of Warwick Castle.—H. D.

MUSCAT OF ALEXANDRIA GRAPES SHANKING.

INFORMATION WANTED.

I HAVE a small house of Muscats under my charge which were planted six years ago, after being fruited one year in pots. On my taking charge two years later I found them in a very unsatisfactory condition. The leaves were thin, pale in colour, and sickly looking, while the few bunches that were on them had shanked badly.

Having ascertained that they were planted in an old border, which is an outside one (and which was originally occupied by Roses, drawn through under the sill and trained to the roof the same way as the Vines), I decided to lift them the following autumn and re-make the border. In doing this I found the site properly drained, and after wheeling all the old soil out, its place was taken by new compost—a mixture of one part turf cut off the limestone, one part sandy loam, and one part horse and pig manure, to which was added some old mortar, burnt earth, and wood ashes. After being made firm the roots were laid out and covered about 6 inches deep with soil; the next year the Vines were much improved in health, and good crops of Grapes followed, but this year the berries have shanked almost wholesale.

An examination of the border revealed the fact that the soil is full of Elm roots, which come under the garden wall from some trees growing outside. Would it be that these hungry feeding roots have impoverished the soil, thus causing the Grapes to shank? I am anxious to find the cause, also a remedy. There is a Lady Downe's about one-third of the way along the house, and this never loses a berry by shanking, yet the Muscats on each side of it are as bad as they can be.—R. M.

BRAMLEY PARK.

THIS, the charming estate of Colonel Ricardo, is situate in the pretty and quaint village of Bramley, which is about four miles below Guildford. The house, which is of the Italian order, lies somewhat low relatively, as much of the surrounding ground runs high. It is a handsome structure, approached by a broad serpentine drive, and has at one end a very fine span conservatory that is always kept wonderfully gay with flowers. But the other day when seen the dominating feature was Campanula pyramidalis, huge plants splendidly grown, both white and blue. Fuchsias also were plentiful and good, and numerous other plants, flowering and foliage. The lawns have several flower beds filled with the usual summer plants, all looking exceedingly gay, and there are plenty of fine trees and clumps of shrubs, Rhododendrons growing most luxuriantly.

But the great floral feature of the place is the herbaceous garden. This was some years since, when Mr. H. Paddon, the present gardener, came to Bramley, little better than a swamp. Getting permission to convert it into a garden the large lakes near the house were cleaned out, and the sediment used to fill the hollow. Gradually large borders, paths, and grassy glades were formed and planted, and nearer the lower half is full to the utmost of hardy herbaceous and bulbous plants in rich profusion, and in huge clumps, furnishing a wonderful wealth of bloom, whilst the upper half is planted with Dahlias, Stocks, Fuchsias, Cannas, Asters, and other similar tender or half-hardy flowers.

This garden was completed in 1887, hence it is known as the Jubilee Garden. On its north and east sides Cupressus Lawsoniana was planted to form a dense shelter, as also a blind to houses beyond, and these have grown so well that they tower up 18 and 20 feet in height, making a very perfect as well as a pleasing break. This garden, thus evolved from a piece of very unsightly waste, is indeed a fine feature at this place. In the kitchen garden hardy flowers are grown in great abundance, and they lend much of beauty to the surroundings.

In one greenhouse, some 28 feet long, Allamanda Hendersoni, trained 5 feet wide all along the roof, is a marvellous sight, being literally a mass of bloom. It flowers for some eight months, furnishing many thousands of blooms in the time. Fuchsias are in this house blooming with exceeding profuseness. It was quite a treat to see these plants so freely used, as in so many gardens gaudy Begonias and similar things have elbowed them out. Outside fruit on Apple, Pear, and Plum trees is rather scarce, but some Apples are very fine, and it is easy to understand that when springs are favourable in this low-lying, moist situation the fruits must be fine indeed. Grapes are good generally—so, indeed, is everything else.

The great glass house feature is the Peach house, a lean-to 52 feet by 15 feet. This house has the front border planted with trees on the cross method. There are twelve of them at about 4 feet apart, each old tree being some 12 feet long by 5 feet high. On several the fruit crops are wonderful, notably on Royal George, at each end, the crops being astonishing, the fruits fine and richly coloured. This is, indeed, one of the best general Peaches in cultivation. Besides these there are Barrington, Crimson Galande, Walburton Admirable, Salwey, Noblesse, Prince of Wales, Alexandra Noblesse, and Dymond; and Violet Hâtive Nectarine. Then on the back wall, furnishing it fully from top to bottom, are Royal George Peach, again a splendid crop; Elruge Nectarine, also a great crop, the fruits of intense colour; Gros Mignonne and Noblesse Peaches. A couple of old riders will be removed in the winter.

Mr. Paddon thinks that while fruits grown on cross-trained trees may not always colour so well as on trees trained close under the glass, yet more fruits are obtained in this way, and it is possible to have greater succession in variety, which where there is but one house is very important. This Peach house would do credit to any garden in the kingdom.—A. D.

HORTICULTURAL SHOWS.

BOSCOMBE.—August 17th and 18th.

This, the second exhibition held in connection with the Boscombe Carnival in Lady Shelley's Park, was a great success. Those interested in horticulture are greatly indebted to A. Beckett, Esq., of Boscombe, to whose spirit and enterprise they have been privileged to witness the best summer exhibition ever held in this neighbourhood. Summer shows have never been a great success in Bournemouth, but this, in connection with a four-days carnival and other attractions, helped to draw an immense concourse of people, estimated to number about 30,000 on Wednesday, the second day of the show.

The Park offers every facility for such a gathering. It is situated in the centre of Boscombe, the eastern portion of Bournemouth, close to the main thoroughfare, and surrounded with Pine and other trees, with ample room for everyone. Mr. Beckett invited a committee of nurserymen and gardeners to manage the horticultural department of the carnival (of whom Mr. J. Spong, gardener to the Dowager Countess Cairns, was the secretary) and gave them a free hand to offer such prizes as would insure some good exhibits. The result was very satisfactory, as good entries were received for the majority of the classes.

£45 was offered for a group of plants arranged for effect—£20, £15, and £10. Seven exhibits were arranged down the centre of a large marquee, 200 by 40 feet, each exhibitor being allowed a space of 15 feet square, with ample room between each group, and in every case they filled the space of 225 feet. The Judges were some time in coming to a decision, but eventually Mr. J. Cypher secured the premier position. All the seven groups were of excellent merit, and the Judges were empowered to award two extra prizes. For twelve stove or greenhouse plants, not less than six in bloom, there were five noble exhibits. Here again Mr. Cypher secured the first prize, and all being of exceptional merit two extra prizes were awarded.

In the fruit classes were some good exhibits, but unfortunately some were damaged in transit, and only second and third prizes were awarded in the collection of nine varieties. Nine collections of vegetables were staged for the three prizes offered in the open division for nine varieties, and an extra prize was given, Lady Theodora Guest being first, and Sir J. W. Kelk second with grand exhibits.

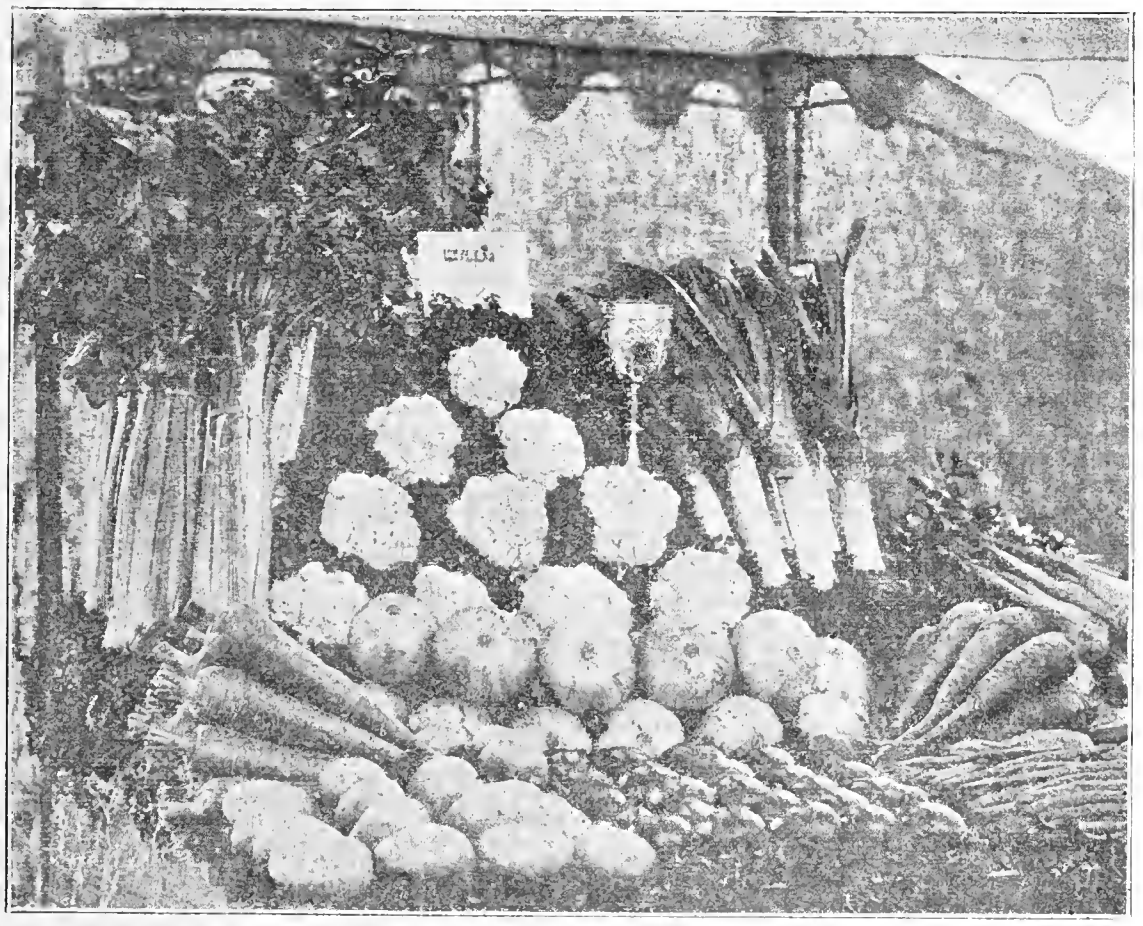

Fig. 28.—Mr. Foster's Collection of Vegetables. (*See page* 192.)

For a collection of Dahlias, with any foliage, arranged for effect on a table space of 10 by 4 feet, only two stands were staged, Messrs. Keynes, Williams & Co., Salisbury, being an easy first. For the time of the year they were a splendid exhibit, his four stands of doubles, twelve each, were simply perfect. Between each stand of doubles were Pompon and Cactus varieties, arranged with their own foliage, rising from the tables to a height of about 2½ feet. The centre stand contained some new varieties, to be sent out in 1898—viz., Britannia, Keynes' White, Mary Service, and Primrose Dame. Varieties, 1897—viz., Bridesmaid, Cycle, Ensign, Starfish, and The Queen, with Fusilier, Harmony, Earl of Pembroke, all the above being Cactus varieties. The other two central stands containing Pompons and Cactus in mixture. Shower bouquets were a fine exhibit, there being nine exhibitors of two, one bridal and one ball, Mr. F. Bailey of Southampton securing the first prize.

In the non-competitive exhibits, Mr. M. Prichard, of Christchurch, had a fresh exhibit of herbaceous flowers of the newest and best. Amongst them were noticed the new double Rudbeckia Golden Glow, and a new decorative Perennial Grass, Stipa gigantea, and Eryngium alpinum, a fine Sea Holly with soft spines. He had also a rather large arrangement of rockwork, representing an Alpine garden, containing about 100 kinds of suitable alpines and perennials, the whole being greatly admired. Mr. C. H. Ratsch, of Christchurch and Bournemouth, had also a stand and group of plants, the most noticeable being a French basket, with large handle, mounted and tastefully arranged, and two specimen Palms, Mr. Tidy, of the Victoria Nurseries, Mr. J. J. Swaffield, the Exotic Nursery, Messrs. G. Watts & Sons, the Palace Nurseries, Bournemouth, and Mr. T. K. Ingram, the Parkstone Nurseries, had each stands and groups of plants. Mr. J. Hobbs, gardener to Lady Shelley, also had a group of miscellaneous plants, the most noticeable amongst them being some extremely fine Cockscombs, and also two fine dishes of Prince of Wales Peaches. In the classes open to those within an area of twenty miles from Boscombe, some capital examples of cultivation were shown, and with thirty-eight classes for cottagers they occupied three other marquees, which were connected together, and of a total length of 180 feet.

A slight mishap occurred on Thursday evening, the large horticultural tent being blown down, but, fortunately, all the exhibits were cleared except two groups belonging to local exhibitors, and they were rather badly damaged. The following prizes were awarded in a few of the open classes:—

Group of miscellaneous plants for effect.—First, Mr. J. Cypher, Cheltenham; second, Mr. T. Wilkins, gardener to Lady Theodora Guest; third, Mr. W. Vause, Leamington Spa; fourth, Mr. W. Peel, gardener to Miss Todd, Sidford Lodge, Shirley, Southampton; and fifth, Mr. E. Wills, Shirley, Southampton. For twelve stove or greenhouse plants, not less than six in bloom, Orchids excluded, Mr. J. Cypher was first, showing Latania borbonica, Cycas circinalis, Kentias Belmoreana and Fosteriana Crotons Chelsoni and montefontainensis, Statice intermedia (a cross between profusa and Holfordi, not yet in commerce) Ixora Prince of Orange, Phœnocoma prolifera Barnesi, Erica Marnoekiana, Stephanotis floribunda, and Rondeletia speciosa. Mr. T. Wilkins was second, Mr. W. Vause third, Mr. E. Wills fourth, and Mr. W. Peel fifth. The successful competitors in the class for one stove or greenhouse plant in bloom were Messrs. J. Cypher, W. Vause, and W. Peel. One stove or greenhouse foliage plant.—First, Mr. W. Peel; second, Mr. Wilkins; and third, Mr. J. Cypher.

For six Caladiums Mr. Wilkins was a splendid first with C. Luddemanni, C. Automne, C. Aida, C. Mdlle. A. Bleu, C. Dr. Lindley and C. Chantini. Mr. W. Mitchell, gardener to J. W. Fleming, Esq., Chilworth Manor, Romsey, was second, and Messrs. G. Watts and Sons, Bournemouth, third. Mr. J. Cypher was first for four Crotons, distinct, with beautifully coloured plants of gloriosa, Flambeau, augustifolius, and Chelsoni. Mr. T. Wilkins was second, and Mr. W. Vause third. In the class for twenty-four table plants, in or out of bloom, pots not to exceed 6 inches diameter.—First, Mr. E. Wills; second, Mr. T. Wilkins; third Messrs. G. Watts & Sons.

Cut flowers were well shown. For twenty-four bunches of cut flowers, stove or greenhouse, separately staged in glasses, with Fern or other foliage, on a table space 15 square feet, Mr. T. Wilkins was first with a bright and light arrangement; Mr. G. Hall, gardener to Lady Ashburton, Melchet Court, Romsey, second, and Mr. W. Vause third.

There was only one collection of hardy flowers, annuals and shrubs excluded, this being sent by Mr. M. Pritchard, who took the first prize. Collections of Dahlias with any foliage, arranged for effect in a table space 10 by 4 feet.—First, Messrs. Keynes, Williams & Co., Salisbury; third, Messrs. G. Watts & Sons, Bournemouth. For two shower bouquets, one ball and one bridal, Mr. F. Bailey was first, Mr. St. Julian Arabin, Southampton, second, and Mr. C. H. Ratsch, Bournemouth, third.

In the class for fruit for a collection of nine kinds, Pines excluded, Mr. H. Higgs, gardener to G. H. M. Ricketts, Esq., Crommore Lodge, Christchurch, took the second prize; and Mr. G. A. Inglefield, gardener to Sir J. W. Kelk, Bart., the third. For three bunches black Grapes J. W. Fleming, Esq., was first with Black Hamburgh, splendid in bunch and finish, but not thinned enough. Mr. T. Boote, gardener to Mrs. F. Ricardo, Burchommage, Christchurch, was second: and Mr. W. Cheater, gardener to Sir Wm. Pink, Shrover Hall, Cosham, third. Three bunches white Grapes.—First, J. W. Fleming, Esq.; second, Mr. G. A. Inglefield: and third, Mr. G. Hall. Mr. H. J. Harvey, gardener to A. B. Sheridan, Esq., Frampton Court, Dorchester, was first for six Peaches, followed by J. W. Fleming, Esq., and Mr. G. A. Inglefield. One Melon.—First, Mr. H. J. Harvey; second, Mr. W. George, gardener to Canon Twells, Bournemouth: and third, Mr. J. Hayes.

For a collection of nine distinct kinds of vegetables Mr. T. Wilkins was first with a splendid exhibit, containing Autumn Giant Cauliflower,

Lyon Leek, and Ailsa Craig Onion, New Intermediate Carrot, Giant White Celery (grand), Perfection Tomato, Windsor Castle Potato, Ne Plus Ultra Runner Bean, and Autocrat Pea. Mr. G. A. Inglefield was second, and Mr. J. Hayes third. For twelve Tomatoes first, Messrs. G. Watts & Sons second, Mr. T. K. Ingram; and third, Mr. C. H. Ratsch.

EASTBOURNE.—August 18th.

Compton Place is an ideal spot for a flower show. This season it was an immense success both as regards exhibitors and attendance. Mr. J. Warren, Handcross Park, Crawley, was well to the fore in stove and greenhouse plants, all being good specimens, and a few of extra merit. He was in front of Mr. T. Portnell, gardener to Sir A. Lamb, Bart., Battle, for eight stove and greenhouse plants, Lapageria rosea splendens and Allamanda Hendersoni being extra good. Mr. Portnell turned the tables in a class for six plants, but was again forced into second position for eight variegated and ornamental foliaged plants. Mr. Warren was well ahead of Mr. Tugwell, gardener to Miss Swift, Beechwood, for eight exotic Ferns, but Mr. Tugwell won for six of the same. The brightest coloured Croton (Sunset) we have seen was in Mr. J. Warren's lot of eight, who also had some good Crotons in his winning exhibit of six ornamental foliaged plants.

Groups of Ferns were numerous and good, Mr. A. McBean, gardener to Miss Wragg, Bracmer, winning from Mr. T. Fuller, gardener to J. Hooke, Esq., Arundel House, Eastbourne. Mr. J. Warren won for six table plants, Mr. Portnell for six pyramidal Fuchsias, and Mr. G. Holding, gardener to Rev. H. V. Shorcland, Eastbourne, for good Zonal Pelargoniums and Coleus.

Fruit was good, especially Grapes and collections. Mr. Tugwell, gardener to Miss Swift, was well ahead in a class for three bunches of blacks with Black Hamburgh. Eight competed here. He also won for three of any white with Muscat of Alexandria, and with Black Hamburgh in the class for a single bunch of any variety. Mr. W. F. Thomas, Wannock, Polegate, was first for collections both of indoor and outdoor grown fruit.

Mr. J. Warren again led Mr. T. Portnell for twelve varieties of stove and greenhouse cut flowers. Roses were fairly good, Mr. Will Taylor, Hampton, winning for thirty-six varieties. Mr. T. D. Young, Eastbourne, followed. In the amateur division R. E. West, Esq., Wray Park, Reigate, was ahead for twenty-four and for twelve varieties. Seven competed in the class for three stands of table decorations, Mr. Sherrard, Hailsham, just beating Miss Smith, St. Leonards-on-Sea. Mr. T. D. Young was successful in floral designs, winning for a superb anchor lying upon a large mirror, for both bridal and ballroom bouquets, and for shoulder sprays and buttonholes.

The chief non-competitive exhibits were from Messrs. J. Cheal and Son, Crawley, Dahlias; Mr. J. Charlton, Tunbridge Wells, Dahlias and herbaceous cut flowers; Mr. F. W. Thomas, Polegate, fruit; and groups from Mr. H. May, Compton Place Gardens, and Messrs. G. F. Scott and Co., Ceylon Nursery, Eastbourne.

DUBLIN.—August 19th.

The Royal Horticultural Society of Ireland contributed, by the autumn Show, held on this date, amongst the greenery of Merrion Square, their quota to the gaieties now dominant in the Milesian Metropolis. Comparatively small as was this Exhibition, it was decidedly fresh and bright; well arranged, too, as far as the limits of one day allowed for staging, judging, clearing up, and clearing away; and last, not least, that capricious gentleman—the clerk of the weather acted exceedingly well as against some very bad behaviour indulged in for the ten days previous.

Probably no prettier scene, in its way, was ever witnessed in Dublin than the decorations provided in compliment to the Royal visitors, and from Merrion Square, looking citywards down Nassau Street, where a thousand flags, banners, and bunting fluttered bravely in the breeze, a charming *coup d'œil* was afforded. The remark made that Dublin had for the nonce outdone itself in the decorative way elicited the information that the citizens instead of carrying out individual notions had put all these arrangements into the hands of a London firm, hence the continuity of effect and harmony of design. However, the "London firm" had naught to do with supplying the hearty cheers of welcome accorded to their Royal Highnesses the Duke and Duchess of York, who, preceded by a prancing cavalcade of Hussars, drove up to the north entrance, with the Viceregal party strong in numbers and happy looking at the loyal greetings they shared with their distinguished guests.

One may be pardoned, surely, for digressing somewhat from the direct subject, such visits to our flower shows, as well as to our shores, being all too few and far between; and although another public function in the way of opening the Countess Cadogan's Textile Exhibition delayed the horticultural visit to a late hour, the Royal visit was, undoubtedly, the attraction which thronged the greensward of the Square with a patient multitude, which 3s. admission (unless furnished with a ticket) was no preventive. Flora and Pomona must, however, have their turn, and they were in some ways worthily represented.

Looking round the plants non-competitive groups were as usual a feature, Glasnevin Botanic Gardens contributing a good lot of plants, some handsome, others curious, and all interesting, including such things as a superb Croton Reidi, to my mind the king of its kind; a flourishing plant of the distinct Nepenthes Burkei excellens, and some of the most curious of the Cacti being dispersed through a well arranged stand of the "rich and rare." Various trade groups comprising small, fresh, decorative plants also helped to furnish the large marquee, in which the competing exhibits were not strong in numbers. Amongst the latter, for twelve foliage and flowering plants Mrs. McComas was awarded the first prize, L. G. Watson, Esq., an old exhibitor, being placed second. For six similar plants, Mr. Colohan, gardener to F. Millar, Esq., led, and for exotic Ferns, Mr. Watson's grand plants, including a fine Todea superba, as usual triumphed; Miss Wallis (gardener, Mr. Kenny) following Mr. Millar, who took second. For Tuberous Begonias (plants), six doubles, the prizes were taken by the enthusiast, Mr. O'Connor, gardener to R. H. McComas, Esq.; the veteran, Mr. Mackenzie, gardener to Mrs. Pease, and Miss Wallis respectively; the prizes for single varieties being competed for and won by the same exhibitors in the same order. Mrs. Pease, Mrs. McCann, and J. Millar, Esq., took first, second and third for six Zonal Pelargoniums. Ivy-leaved varieties were best from Mrs. Pease, and second best from J. Millar, Esq. Sir Roger Palmer showed the best specimens exotic; Mr. T. Byrne, gardener to Geo. Drimmie, Esq., having the best specimen Orchid. Mr. T. Goff, Mrs. McCann's gardener, in a well-filled class for six Coleus in variety, had six matchless beauties which captivated the eye of the most critical of the critics; the Right Hon. J. Meade, LL.D., and Mrs. Pease being second and third.

Stands of cut blooms bring one first to the Dahlias, of which the Show and Fancy section was probably not so strong a feature as usual in Dublin. In the class for thirty-six, in twenty-four varieties, Lord Ashbrook, The Castle, Durrow (gardener, Mr. McKellar), was first; Mr. McLennan, for Lord Carew, Castleborough, being second. Mr. Rigg showing the best twenty-four in twelve varieties for Lord Cloncurry; Mr. McKenna, gardener to the Lady Emily Howard, Bury, second; third, W. F. Darley, Esq. (Mr. Leonard, gardener). Cactus Dahlias were well shown, noticeable among the stands being Gloriosa, and the rich, dark satiny Matchless; Lord Carew, Lord Cloncurry, and Lady E. H. Bury taking the honours respectively. Lord Cloncurry had the best stand of twenty-four Roses in twelve varieties, and also the best stand of twelve; E. D'Olier, Esq., sending from Knocklin, Bray, the best stand of twelve Teas. Gladioli were sparsely shown, H. Jervis-White, Esq., having the first prize stand of twelve spikes. Twelve varieties of Zonal Pelargoniums were awarded first, second, and third to Lord Ashbrook, Geo. Drimmie, Esq., and Mrs. Pease.

A challenge cup, value 10 guineas, presented by Lady Ashtown, to be won three times before finally claimed, for forty-eight blooms of Begonias, half double, half single, went to Lord Ashbrook, Mrs. Pease being second; leading honours in a smaller class of double varieties going to the same exhibitors, also for a similar class of single varieties. Passing over some few classes for Asters and Marigolds, that enthusiastic amateur, H. A. Smallman, Esq., came second to Lord Cloncurry for six bunches of Carnations, who took the lead in the larger class of the same popular flower, Surgeon-General Beaumont being second here, with B. Philipson, Esq., of Dalkey, third. The prize for twelve bunches of Eckford's Sweet Peas, presented by the eminent raisers, was carried off by Mr. Mitchison, gardener to the Hon. Col. Crichton. Nurserymen's classes for Dahlias and Roses were led off by Messrs. Campbell of Blantyre, N.B., and Dicksons of Newtownards, the first having the best Dahlias, whilst, it goes without saying, that the great Irish Rose growers held front rank on their own ground among the Roses, their forty-eight being in fine form for the season.

Some few classes are unavoidably passed over, though a passing notice must be given to the fine stands of Begonia blooms and the grand display of Carnations not for competition. The Begonias from Cork, 400 blooms being staged by Hartlands, were a marvel of size, colour, and freshness; and from Mr. Watson of the Clontarf Nurseries came a goodly array of his grand Carnations, which were well represented and took honours at Chester previously. Mr. R. Jameson of the Sandymount Nurseries was a bit squeezed at one end of a tent with a good group of miscellaneous plants, and Mr. Ramsay's portly manager looked well satisfied in showing off his well-grown plants from the Ball's Bridge Nurseries.

Fruit must be briefly surveyed. Lord Holmpatrick's prize for six bunches of Grapes in three varieties went to the Lady E. H. Bury; Robt. Tedcastle, Esq., of Marlay, second; third, T. Bradshaw, gardener to the Marquis of Downshire. In the first and second prize stands Cooper's Black was conspicuous by superbly coloured high-finished bunches, being far and away the best black Grape shown. Other classes in the Grapes were fairly well filled, Muscat of Alexandria generally lacking colour. First for a collection of twelve dishes of fruit was taken by the Lady E. H. Bury; Mr. W. Bradshaw, gardener to Sir David Harrell, K.C.B., coming second, the Marlay collection third. Good Peaches from E. D'Olier, Esq., gained him first prize. Good-looking specimens filled the Melon classes, the best green-fleshed coming from the Marquis of Downshire; scarlet, Lady Bury.

For the best twelve varieties of vegetables Lord Carew staged a fine tray, which included samples of Carrots and Parsnips as seldom seen on this side. Potatoes were not a strong feature, Sir James Mackey's prize for twenty kidneys and twenty rounds going to the Right Hon. I. M. Meade. Doubtless the indefatigable Secretary, G. M. Ross, Esq., concluded his hard day's work with the satisfied feeling that "all's well that ends well," for ere another day had dawned came a deluge, and one regretfully appends to the recent satisfactory notes sent from here upon things generally a qualification proceeding from inclement weather which, unless a change comes quickly, cannot but be regarded as serious.—K., *Dublin.*

CRYSTAL PALACE.—AUGUST 20TH AND 21ST.

THE twelfth great National Co-operative Flower Show, under the auspiees of the Agricultural and Horticultural Association, was held in the Crystal Palace on the above dates. This exhibition has usually been favoured with fine weather, but this year, during the opening day, rain fell almost incessantly. This was unfortunate, as it would doubtless militate against a very large coneourse of visitors. We shall deal in our report with Section II., which was confined to members or eustomers of the Assoeiation or their gardeners and employés, the exhibits being staged and adjudicated upon on Friday ; Seetion I., for amateurs and eottagers, being staged on Saturday. This year there was a notable departure in the plaee of staging, this having hitherto been done in the centre transept, whereas this season it was in a splendid marquee that had been ereeted on the terrace. It was the more unfortunate that rain should fall, as many people who entered the Palace would not venture even such a short distance to see the show.

So far as numbers were concerned there was an appreciable falling off ; indeed, in some of the classes there were no entries at all. This was especially noticeable in the classes for collections of vegetables, which, as a rule, make a very fine display. Only in one class were there any exhibits. While quantity was less, we are inclined to the opinion that amongst the fruit and vegetables, especially the latter, the quality was decidedly higher. There has often been at these shows a coarseness that ought not to be seen ; but on this occasion size had not apparently been such a desideratum with the growers. All the green Cabbages, however, were far too large for the table, and it is hoped that next year these will have come down to reasonable dimensions, when the table qualities will be decidedly enhanced. The display of Potatoes was magnificent, and we doubt if a finer collection has ever been seen at one of these shows. Plants were not of particular merit, but some charming flowers were noticed.

The class for a collection of vegetables in ten distinct kinds grown in the Southern district was won by Mr. C. J. Waite, gardener to the Hon. W. P. Talbot, Glenhurst, Esher. The produce represented included Leek Giant, Carrot New Red Intermediate, Cauliflower, Beet Blood Red, Celery Mammoth White, Onion Ailsa Craig, Searlet Runners, Tomato Perfection, Cucumber Telegraph, and Potato Satisfaction. Mr. A. Basile, gardener to O. L. Powells, Esq., Woburn Park, was second. His Potatoes, Peas, Marrows, and Celery were good. Mr. R. Wadham, Steeple Aston, was third ; and Mr. J. Holton, Oxford, fourth.

The competition in the Onion classes was keen, and some splendid bulbs were staged. Mr. R. Chamberlain, Reading, was first for spring sown with fine Ailsa Craig ; Mr. A. Basile for White Spanish ; and Mr. C. J. Waite for winter Onions. In each class nine bulbs had to be shown. The last named exhibitor staged grand Parsnips, the roots being clean and straight. Peas were not particularly well staged, almost all being old, and many of the pods not filled. Mr. C. J. Waite won the single dish of One and All Exhibition Marrows, and Mr. A. Basile for a dish of any other variety.

The dishes of Runner, French, and Longpod Beans were very numerous and excellent in quality. The first prizewinners in the respective classes were Messrs. J. Holton, who was to the front in the Runner and French Bean classes ; Mr. R. Chamberlain in the Longpod ; and Mr. G. Palmer, Oxford, for Broad Windsor. There were fourteen exhibits of Tap-rooted Beets, Mr. C. J. Waite winning. For Turnip-rooted, in which there were about eighteen exhibitors, Mr. R. Wadham took the premier award. Green Cabbages were far too large throughout. Mr. A. Basile won with three immense heads, which, however, were clean and fresh. Nearly all others were coarse. Mr. J. Martin, Horsham, had three grand Red Cabbages, as had Mr. C. J. Waite, who took second place.

Potatoes were excellent, and made one of the best features of the Show. There were eight exhibitors of six varieties, the first prize going to Mr. A. Basile, who showed Satisfaction, Supreme, Up to Date, Flour Ball, Windsor Castle, and International. Mr. J. Holton was a fair second, and Mr. R. Webster, Bromley, third. Mr. J. Holton took first for a single dish of white kidney, while for coloured kidneys Mr. R. Wadhams was first. The best white rounds came from Mr. C. J. Waite, and Mr. J. Holton the best coloured rounds.

Mr. J. Holton staged superb One and All Intermediate Carrots, as did Mr. R. Wadham the ordinary Intermediate. Mr. J. Holton's Long Red Surrey Carrots were splendid. Cauliflowers were not very grand. Mr. A. Basile was first for three with nice heads. Mr. J. Holton staged fine Red and White Celery, taking first in each case. Herbs were numerously and well staged by several competitors.

Culinary Apples were largely shown. For three dishes Mr. A. Basile was first with splendid specimens ; Mr. A. Galvin, Sittingbourne, having the best dessert varieties. Mr. T. Osman secured the first prize for a collection of open air fruit, and was closely followed by Mr. R. Wadhams.

Mr. C. J. Waite had the best black Grapes, and Mr. Taylor the best white. Peaches and Nectarines, Pears, Plums, Gooseberries and Currants were largely staged. Amongst the prizewinners were Messrs. C. J. Waite, A. Basile, A. Galvin, W. Taylor, R. Wadham, J. Humphrey, and J. Holton.

The second day was the industrial day, the products representing the devotion and skill of the wage-earning community in various parts of the country. The display, as a whole, was altogether creditable and commendable. Vegetables, with the exception of one or two kinds, were splendid, and competition great in most of the classes. Potatoes, Carrots, Parsnips, Shallots, Onions, Peas, Beans, and Celery, in fact nearly all kinds, would be hard to surpass. Turnips were, perhaps, a little weak, and Cabbages too large and coarse, but taking the display as a whole it was decidedly meritorious.

Plants and flowers were never so well represented at these Shows before, and marked improvement was apparent in the arrangement of flowers. Still there were many examples of close packing, as if some of the earnest competitors had tried to crowd the greatest possible number into the smallest possible space. When they find, however, that this is not the way to win prizes improvement will follow, as it has done in numbers of instances.

An effort is being made to encourage flower culture among children attending schools. During the past spring the Council of the Association commenced by offering prizes for the culture of pot plants to the children in twenty-seven London schools. No less than 1627 competitors entered, and the results were exhibited before the recent breaking up for the holidays. So much interest and enthusiasm was shown that Mr. Edward Owen Greening, at whose instance the experiment was made this year, hopes to see a great development of the movement in future years.

The exhibition, which filled a marquee 500 feet long by 40 feet wide, on the Terrace, was highly successful, and the courtesy of the several officials beyond praise.

NATIONAL CARNATION AND PICOTEE SOCIETY

(NORTHERN SECTION).

THE annual exhibition of the above Society was held at the Royal Botanical Gardens, Old Trafford, Manchester, on Saturday, August 14th. Considering the excessive heat which prevailed a few weeks ago the blooms were remarkably good, and taken altogether the exhibition was a grand success, comparing favourably with those held in previous years.

For twelve flakes and bizarres, dissimilar, Mr. T. Lord, Todmorden, was first with fine flowers of George, Master Fred, Gordon Lewis, J. S. Hedderley, Bruce Findlay, Magpie, Mrs. Rowan, Robt. Houlgrave, Admiral Curzon, Mrs. T. Lord, Guardsman, and Thaddeus. Mr. J. Edwards second ; Mr. Geo. Thornley third ; and Mr. H. Geggie fourth.

For six bizarres and flakes, dissimilar, Mr. C. Head, Hebden Bridge, was first ; Mr. C. F. Thurstan, Wolverhampton, second ; third, Mr. J. Lees ; fourth, Mr. J. Whittaker. In the class for twelve selfs, not more than two flowers of any one variety, Mr. T. Lord, Todmorden, was first with Germania, Nero, Mrs. T. Helliwell (a grand new coral pink self), Germania, Albino, Ruby, Mrs. Fred, Joe Willet, Topsy, Lady Agnes, Vesuvius, and Mr. T. Helliwell ; second, Mr. Joe Edwards, Blackley ; third, Mr. Wm. Kenyon ; fourth, Mr. L. B. Bleackley. Six self Carnations, not more than two flowers of any one variety, Mr. C. F. Thurstan, Wolverhampton, was first ; Mr. E. Shaw, Moston, second ; Mr. A. R. Brown, third ; Mr. D. Walker, fourth ; and Mr. Ed. Kenyon, fifth.

In the class for twelve Fancy or yellow ground Carnations, not more than two flowers of any one variety, Mr. A. R. Brown, Birmingham, was first with grand flowers of Voltaire, Mrs. A. Tate, Voltaire, Stadtrath Bail, The Gift, Eunomia, Monarch, Virgo, Janira, The Dey, Virgo, and Mr. Nigel ; Mr. C. F. Thurstan, Wolverhampton, second ; third, Mr. D. Walker, Kilmarnock ; fourth, Mr. T. Lord ; fifth, Mr. J. Edwards. Six Fancy or yellow ground Carnations and Picotees, with not more than two flowers of any one variety.—First, Mr. F. Steele, Hanley, with Monarch, President Carnot, Ladas, Monarch, Stadtrath Bail, and Ladas ; second, Mr. J. Brocklehurst ; third, Mr. W. Kenyon ; fourth, Mr. J. Lees, Premier Carnation, Mr. J. Whittaker, Royton, with Robt. Houlgrave, S.B.

Single blooms were admirably shown, and the awards were made as follows :—Searlet bizarres.—First, Mr. T. Lord, with Robt. Houlgrave ; second, Mr. L. B. Bleackley, with Robt. Houlgrave ; third, Mr. Geo. Thornley, with Robt. Houlgrave ; fourth, Mr. Jas. Turner, with George ; and fifth, Mr. H. Geggie, with seedling. Crimson bizarres. First, Mr. T. Lord, with Master Fred ; second, Mr. J. Edwards, with Jos. Lakin ; third, Mr. T. Lord, with Master Fred ; fourth, Mr. J. Edwards, with J. S. Hedderley ; fifth, Mr. Geo. Thornley, with Edith Annie. Pink and purple bizarres.—First, Mr. T. Lord, with Edith Annie ; second, Mr. Jas. Etherington, with Mrs. Barlow ; third, Mr. T. Lord, with Sarah Payne ; fourth, Mr. Jas. Etherington, with Mrs. Barlow ; fifth, Mr. Joe Edwards, with Ellis Crossley, Scarlet flake.—First and second, Mr. T. Lord, with Sportsman ; third, Mr. Ed. Kenyon with Guardsman ; fourth, Mr. Jas. Turner, and fifth, Mr. Joe Edwards, both with Sportsman. Rose flake.—First and second, Mr. Joe Edwards, with Mrs. Rowan and Mrs. Gunn ; third, Mr. A. R. Brown, with Tudor ; fourth, Mr. T. Lord, with Mrs. T. Lord ; fifth, Mr. J. Whittaker, with Cristagalli. Purple flake.—First and second, Mr. T. Lord, and third, Mr. Joe Edwards, with Gordon Lewis ; fourth, Mr. J. Edwards, with Jas. Douglas ; fifth, Mr. J. Lees, with Billy Henderson.

In the important class for twelve blooms, distinct, Mr. T. Lord, Todmorden, was first with finely developed blooms of Mrs. Sharp, Lena, Mrs. Coldridge, Brunette, Amy Robsart, Nellie, Somerhill, Little Phil, John Smith, Muriel, Thomas William, and Morna ; Mr. W. Kenyon, Bury, second ; third, Mr. Joe Edwards ; fourth, Mr. E. Shaw ; fifth, Mr. Jas. Turner. For six blooms, distinct, Mr. C. Head was first, with Brunette, Mrs. Sharp, Thomas William, Muriel, Nellie, and Mrs. Wilson ; Mr. C. F. Thurstan, second ; Mr. J. Lees, third ; Mr. Ed. Kenyon, fourth ; Mr. F. Steele, fifth ; Mr. J. Whitaker, sixth.

In the classes for single blooms there were some fine flowers shown. For heavy edged red, Mr. T. Lord was first and second with John Smith and Brunette ; Mr. E. Shaw, third and fifth, with Morna, and Mr. W. Kenyon fourth, with Mrs. Wilson. Light edged red.—First and fifth

Mr. J. Edwards, with Thomas William; second, Mr. C. F. Thurstan, with Mrs. Gorton; third and fourth, Mr. T. Lord, with Thomas William and Mrs. Gorton. Heavy-edged purple.—First and second, Mr. J. Edwards with Polly Brazil; third and fourth, Mr. T. Lord, with Muriel, and fifth, Mr. C. F. Thurstan, with Amy Robsart. Light-edged purple.—First, Mr. T. Lord, with Somerhill; second, Mr. C. F. Thurstan; third and fifth, Mr. J. Edwards; fourth, Mr. E. Shaw, all with Mary. Heavy-edged rose, scarlet, or salmon.—First and fifth, Mr. T. Lord, with Mrs. Sharp; second, Mr. C. Head, with Mrs. Sharp; third and fourth, Mr. W. Kenyon, with Mrs. Sharp and seedling. Light-edged rose, scarlet or salmon.—First and fourth, Mr. T. Lord, with Favourite and Nellie; second, Mr. J. Edwards, with Nellie; third, Mr. C. F. Thurstan, with Nellie, and fifth, Mr. W. Kenyon, with Favourite. Premier Picotee, Mr. C. Head, Hebden Bridge, with Nellie, light scarlet edge.

THE YOUNG GARDENERS' DOMAIN.

Strawberries.

With reference to "A Young Scot's" article on page 155 I notice he does not mention Elton Pine, a late Strawberry, that does remarkably well with us, it being loaded with a large crop of bright coloured fruit.

Our soil is of a clayey nature, which seems to suit it admirably, some of the beds having been planted four years, and are still bearing large crops of fruits. The fruit is rather acid for table use, although excellent for preserving. We commenced picking from the plants during the last week in July, and are still gathering large quantities from August 14th.

Speaking to a large grower of Strawberries in this locality he said Elton Pine was a failure with him, his soil being much lighter. Royal Sovereign did well, especially after the first year,

Some gardeners say it goes patchy or blind in Scotland; it did with us, but I cannot say if all the layers were taken from fruiting plants, which may account for some of the blindness. Vicomtesse Hericart de Thury does remarkably well, bearing heavy crops of large fine-flavoured fruit.

We commenced to pick on early borders from John Ruskin on July 8th, followed by Noble and Royal Sovereign. The nights have been very cold all the season, even after hot days, and made everything very late.—A. C. W., *Balcarres.*

The Means and Modes of Propagating Plants.

(*Continued from page* 107.)

Mention has been made of bulbs, tubers, and tuberous roots, but their nature has not been exactly explained. A bulb may best be described as an underground bud, which it is in point of fact. Its name is obtained from the Greek *bolbos*, meaning a globular root. The coronal of fibrous roots by which the bulb derives its nourishment from the soil are produced annually, dying with the leaves when the year's work is done, and the bulb takes its period of rest. While in activity the bulb takes in a store of sap, which has been elaborated in the leaves, and after the resting period leaves and blossoms are produced under favourable conditions.

Bulbs are not all alike in form. Some, like the White Lily (Lilium candidum) and many others of the tribe, are formed of scales that loosely overlap each other, and are easily detached. In Hyacinths and Onions they are in closely packed layers. In other plants, such as the Crocus and Gladiolus, the corm is neither in layers nor scales, but solid. The Cyclamen is another familiar example of this kind of corm. All these different forms vary in their mode of reproduction. In the Gladiolus cormlets form round the base, and may be grown into perfect plants. The scales of bulbs will also produce bulblets. In the Crocus a new corm forms on the top of the old one when its flowers have perished and its long grass-like leaves decayed.

Bulbous-rooted plants may be propagated by seeds as well as by offsets and bulblets; tuberous plants also are propagated by seeds as well as by means of their tubers. With such plants, however, propagation by seed leads to the production of new varieties, while propagation by bulb or tuber must of necessity be resorted to in order to insure the maintenance of the same variety. Thus new varieties of the Potato are produced from seeds, the result of cross fertilisation, but if any variety raised from seed exhibits qualities which render its preservation and increase desirable, this must be effected by buds from its tubers. Tubers are expansions of underground stems studded with eyes or buds, and stored with starchy or feculent matter, which affords nourishment to the buds until their root growth is sufficiently advanced to admit of their deriving support direct from the soil.

The Turnip, Parsnip, Carrot, Beetroot, and Radish should be termed tuberoids rather than tuberous roots; they resemble tubers in many points, but they are not reproduced from offsets cut from them, but wholly from seed. Propagation by natural methods are six in number—namely, (1) by seed; (2) by germs or offsets; (3) by slips; (4) by division of the plant; (5) by runners; (6) by suckers; and under each method a special mode of treatment is necessary. Thus in propagation by seed it is requisite to use seed the vitality of which is unimpaired. Seeds retain vitality for one or two years only under ordinary circumstances. It is better to sow seed saved during the previous season, or at the utmost not more than two seasons old. If it be desired to preserve the vitality of seed for a longer period than two years, it is necessary to keep it in airtight receptacles. In addition to age, due regard must be had to soil, season, and other circumstances.—C. W. M.

(To be continued.)

HARDY FRUIT GARDEN.

Destroying American Blight.—The white cottony substance now evident on Apple trees infested with this pest encloses the living insects which work so much damage to the stems, branches, and young shoots Persistent effort is required in order to exterminate the pest. Its presence now being easily detected, it is a suitable time to go over the trees and endeavour to destroy as many of the insects as possible. They are very active now, and most probably increasing rapidly before resting for the winter, during which time they are very inconspicuous; but the damage committed remains visible in the form of excrescences and swellings round the wounds or cracks. It is there that the insects secrete themselves.

Dress the trees only at the parts infested, using methylated spirit or petroleum. Dip an old half-worn painter's brush in the oil, shaking it partly dry so that the oil does not run down the bark when applied. Brush well into the crevices so as to reach as many insects as possible. Slender shoots in the upper parts of trees infested with blight may be cleansed to a great extent by forcibly applying water from a garden engine. In the winter a petroleum and softsoap emulsion may be applied as a dressing in a more thorough manner than can be safely carried out now.

Protecting Ripening Fruit.—*Trapping Earwigs.*—Peaches and Nectarines ripening on walls are liable to attacks from earwigs, which soon disfigure the fruit. Traps should be laid for them, and these may consist of lengths of Broad Bean stalks about 9 inches long. Lay them between the branches in the vicinity of the fruits. Examine them every day, blowing out the insects and destroying them.

Wasps.—It is necessary to guard choice fruits against wasps. Where the number is limited, and the size and quality of the fruits are worth it, each may be protected in the safest manner by enclosing in a muslin bag, tying securely. The next best method is to enclose the whole tree with netting of fine mesh or thin tiffany. Wide-necked bottles of beer, sugar, and water hung among the branches will attract both wasps and flies. Wasp nests may be destroyed by pouring tar down the holes. Another remedy is to thoroughly saturate a piece of rag with strong turpentine, attach it to the end of a stick, and thrust into the hole, which should be closed with a heavy lump of turf.

Woodlice.—These insects are partial to ripe fruit. They lodge in holes in the walls, and are encouraged by the presence of rubbish or dead leaves. Prevent all accumulation of such, also maintain the ground at the base of walls moist, which is a deterrent.

Netting Small Fruit.—To preserve ripe fruit of Gooseberries, Currants, and Morello Cherries as long as possible the trees must be netted over for preventing the access of birds. In wet weather the trees ought also to be protected from rain.

Gathering Early Fruit.—Keswick Codlin, Hawthornden, and Duchess of Oldenburg Apples may be gathered and stored carefully in cool quarters. Any fruits that do not part readily from the trees when lifted should be left a little longer. Citron des Carmes, Green Chisel, and Williams' Bon Chrêtien Pears require gathering immediately they can be easily detached from the spurs. By keeping them in a cool, dark place for a week they finish well and are of good flavour. If allowed to ripen on the trees they are frequently mealy, and consequently not properly appreciated, as it otherwise would have been.

Fallen fruit must be gathered up daily, utilising the soundest for immediate use, destroying the half decayed. These fruits are usually infested with the Codlin moth grub, which is the cause of their falling in calm weather. Grub-eaten and bruised fruit will not keep. In utilising them it is necessary to remove the infested parts only, and the other portions will be found perfectly wholesome.

Raspberries.—The canes which have borne fruit this season ought now to be cut down, as well as the weakest of the present year's growths. Leave four to six of the stronger canes to each stool for next season's fruit bearing. By the removal of superfluous material now the growths retained have every opportunity of receiving the full benefit of light and plenty of air, which will accelerate their ripening. The firmer, harder, and browner in colour the canes become, the better they are for producing fruit.

When grown in lines, a little thinning out may be necessary, dispensing with the weaker. Sufficient growths must be left to furnish the wires or trellis when trained in. Suckers springing up at a distance from the main crowns dig out, unless wanted to increase stock. The best of them may then be left until planting time in late autumn, just as the leaves are falling.

After pruning in the above manner, fork up the strong weeds, and hoe down the smaller. Loosen and break up with a fork hard trodden portions of ground, but avoid digging near the stools, which destroys the fibrous roots. A dressing of rich manure laid on the surface will have its nutriment gradually washed into the soil by the rains. It will also act beneficially in multiplying the fibrous roots and attracting them to the surface, where every endeavour should be made to retain them by giving attention of this nature each year.

FRUIT FORCING.

Vines.—*Early Forced Vines in Pots.*—These for starting in November must not be allowed to become dust dry at the roots; let the soil be kept moderately moist; but, on the other hand, excessive moisture is most inimical, as it causes the tender rootlets to decay, and the buds start very indifferently in consequence. The Vines will now be at rest, the wood ripe, the laterals cut close home, and the canes shortened to about 6 feet, more or less, according to the situation of the plump eyes. Whilst the cuts are dry dress them with styptic or patent knotting to prevent trouble from bleeding. They should be kept in a cool airy house.

Earliest Forced House.—It is not necessary to wait until all the leaves have fallen before pruning matured Vines for early forcing, but the wood must be brown and hard, and the leaves turning yellow. The pruning will cause the Vines to rest quickly and thoroughly. If in good condition they will afford bunches quite large enough when pruned to a couple of buds of the base; but if the Vines are weak from overcropping or a long course of forcing, the spur shoots may be left a little longer with a view to large bunches. When this method is adopted take shoots from as near the base as possible when growth commences. These should not be allowed to carry any fruit, but be stopped at about the sixth leaf, and the laterals at the first leaf, and subsequently as produced. Such shoots are sure to form good buds; the extra foliage will tend to invigorate and support the fruit on the other shoot, which can be cut away in due time in favour of the one for fruiting the following season. This alternate system of fruiting neeessitates keeping the shoots further apart for development and exposure to light and air. If the Vines are grown on the extension system it will only be necessary to cut back to plump buds on well-ripened wood, being guided by the space at command, for there must be no overcrowding. It is important that the Vines be thoroughly cleansed, and the house also. The woodwork should be washed with softsoapy water and a brush, the glass with clear water, limewashing the walls, placing a handful of flowers of sulphur in each pailful of water.

Wash the Vines by means of a brush with sulphate of iron, 1 lb. to 1½ gallon of water. It is good against most fungoid enemies of the Vine. Any weakly Vines, or those in an unsatisfactory state, may be improved by removing the soil down to the roots, and substituting fresh loam with a sixth part of old mortar rubbish, a fifth of sweetened horse droppings, and about a stone (14 lbs.) of crushed bones to each cartload of loam. Lift any roots available for the purpose, laying them out upon the fresh compost, and cover them about 3 inches deep. If long and bare of fibres they may be notched on the under side at about 18 inches distance apart, so as to induce the emission of fibres. This is best done over the whole extent of border before the leaves fall. It is a mistake to allow Vines to become very dry at the roots. Comparative dryness is desirable, yet great injury is done by allowing the soil to become dust dry. Where old lights are at command they may be used for throwing off heavy rains from outside borders, otherwise do not use any covering for the present.

Young Vines.—Those that have made strong growths, and are late in ripening, should be assisted with fire heat, maintaining a minimum of 65°, and a maximum of 75° by those means, continuing it until the wood is ripe, accompanied with free top and front ventilation. Discourage any further growth by keeping the laterals well in hand, removing them as they appear, but be careful not to cause the principal buds to be forced into growth by too close stopping.

Late Grapes.—These are now colouring and ripening rapidly, but many are a long way from being properly finished, which, in almost all cases, is due to the late starting of the Vines. Late Grapes require a long time to perfect, hence there is nothing like letting them have August and early September for this purpose, as then the days are generally bright and the nights comparatively cool, so that the Vines get rest more or less, and thus finish heavier crops than it is possible to perfect earlier in the season. Keep the laterals well thinned, letting the main leaves have plenty of light, but a little lateral extension where it does not interfere with that favours root action and better supplies of nourishment. A good spread of foliage over black Grapes is an advantage, especially Hamburghs, but Muscat of Alexandria colours better with the light shining between the laterals, and similar remarks apply to white Grapes generally. Direct exposure to powerful sun, however, is not advisable, as these Grapes are somewhat liable to become brown when the sun acts powerfully upon them whilst wet or covered with an imperceptible dew. Avoid large reductions of foliage at a time, as this gives a sudden check, and may result in shanking, or even prejudice the ripening process, but attend to them frequently for pinching. Maintain a night temperature of 70° to 75°, falling 5° to 10° during the night, increasing to 80° to 85° by day, up to 90° in the afternoon, accompanied with a free circulation of air in the early part of the day, and a moderate amount day and night—always enough to insure a circulation.

Make the most of the next month or six weeks in case of Grapes that are late in ripening, for when the days are short ventilation cannot freely be practised, and unless Grapes have a moderate amount of air moisture when ripening they do not swell freely but are liable to shrivel, particularly Muscats, and it is not the moisture that causes Grapes to crack and spot, but the confined atmosphere—moisture condensed preventing evaporation from the surface of the fruit. Grapes well advanced in ripening may have the atmospheric moisture reduced; those only colouring should have only a moderate amount of moisture to assist their swelling, not neglecting to apply water to the roots, but it will hardly be further needed by outside borders, whilst it must be given to inside borders as required.

When the Vines are heavily cropped, and not colouring so well as desired, the Grapes should be given time, not pinching them for due supplies of nourishment, and not very closely restricting the laterals, though there are few of these when the crops are heavy; but some superphosphate and nitrate of potash (two parts the first to one part of the latter) act well, using 3 to 4 ozs. per square yard, and washing in moderately. Let the night fall to 60°, or even lower; but use fire heat in the daytime so as to maintain a temperature of 70° to 75°, and even at night allow a little air, so that when the sun falls upon the house in the morning the atmosphere will move and the Grapes warm equally with it, thus avoiding deposition of moisture on the berries. This is serviceable; but the thing is to feed earlier, and get material into the Vines and Grapes for changing at the proper time into jet black or golden amber colour, keeping free from red spider and not overburdening the Vines.

Pines.—*Potting Rooted Suckers.*—Suckers obtained from the summer fruiting plants will soon be ready for potting. It is well to divide the plants. The strongest should be shifted into their largest pots as soon as ready, employing 10 or 11-inch pots, according to the variety, affording them a position near the glass in a light, airy house, keeping the plants gently moving during the winter. Those so started will be readily excited into fruit next May or June, and will afford a good successional supply of fruit in late summer or autumn. In other plants suckers from the summer fruiters not large enough to shift into the fruiting pots winter best in 7 or 8-inch pots, transferring them to larger as soon as ready in spring; which, with suckers of Smooth-leaved Cayenne that were started last March, will afford a successional supply of Pines through the winter months.

Re-arranging Pine Plants.—A re-arrangement of the plants should now be made in order to separate the fruiting from the non-fruiting plants, as many of those that were started from suckers of last summer's fruiting plants will have fruit swelling. Those plants not fruiting will have completed their growth, and should have air very liberally for the next six weeks, when the temperature exceeds 80°, maintaining the bottom heat steady at 80°, and all plants well established—that is, well rooted, should have a bottom heat of 80° to 85°, but recently potted suckers, or those which have not roots well established in fresh compost, should have a bottom heat of 90°, steadily maintained to insure speedy rooting.

Fruiting Plants.—Those swelling off their fruits should have moderate atmosphere, but not a large amount, or it may enlarge the crowns unduly, and excess at the roots causes the fruit to become black at the centre. Admit a little air at the top of the house early in the morning, so as to allow of any superfluous moisture escaping before the sun's rays act powerfully upon the fruit. Any fruit it is desired to retard should, when fairly coloured, be removed to a rather shady house, admitting abundance of air.

THE BEE-KEEPER.

FEEDING BEES.

It is beneficial to the bees to be supplied with their winter stores as early as possible in the autumn. In fact the closer we imitate Nature in this respect the better it will be for the welfare of the bees in the future. In their natural state, directly a surplus of honey is obtained, it is stored in their combs and sealed over. It may be in the spring, when the honey is obtained from the early fruit tree blossoms, or at midsummer from the White Clover, or in the autumn from the Heather. But from whatever source it is obtained, the bees, if not interfered with, will seal it over directly it is in a fit condition.

Honey treated in this manner will keep in good condition for several years. In feeding bees artificially, I have proved how beneficial it is to have all stocks fed up as early as possible in August. If feeding is delayed till after the middle of September, and a cold spell of wet weather sets in, although the bees may store the syrup provided for them, they will not seal it over, and this is often the cause of dysentery. Bees which are left to take their chance in some hollow tree, or in the roof of an old building, I have observed, are seldom found to have this disease.

It is advisable to examine all stocks before placing the feeders on them, as some will probably require more than others. Usually those that have been used for extracting purposes, require more feeding than those worked for comb honey. The reason for this is, that whilst extracting is going on, the bees, in their anxiety to fill the supers, are constantly carrying the honey from the brood nest for that purpose; whereas with sections of comb honey, they are allowed to remain on the hive till well finished, and unless closely watched the bees become short of storage room in the supers. The honey is then stored and sealed over in the outside combs of the brood nest. It is then allowed to remain, and there is often sufficient in such hives to provide ample stores for a strong colony until the following spring.

MAKING SYRUP.

Syrup for autumn feeding should be made of the consistency of good honey. If made thin, such as is recommended for spring feeding,

it would be too watery, and a great amount of moisture would have to be evaporated before being in the right condition for sealing over. Syrup for autumn feeding is best made in the proportion of 7 lbs. of sugar to 3 pints of water. This should be placed over a clear fire and kept constantly stirred until it boils. It should then be taken off, and will be ready for use as soon as cool enough.

During the boiling process add a little vinegar and salt. The former will prevent the sugar candying, which it is liable to do if kept for any length of time before being used, or if it has been boiled too long. The plan which I practise, and which I recommend to bee-keepers who have numerous colonies of bees, is to place 2 cwt. of sugar in a large copper and boil it all at once. This is a great saving of labour, and the syrup is quite as good as when boiled in smaller quantities.

Pure cane sugar should always be used. In my apiary I always use the best granulated; bees invariably winter well on it. Beet sugar is sometimes substituted for the above; but by dealing with a house of good repute the various sugars may be depended on. The vessel from which the syrup made from cane sugar has been poured will not contain any sediment, which is not the case when Beet sugar has been used, as there is often a blue sediment left after the syrup has been poured off, and when such is found steps should be taken to obtain the sugar from another source.

QUANTITIES OF STORES REQUIRED.

Opinions differ somewhat as to the amount of stores necessary to carry a strong colony safely through the winter. There is, however, a vast difference in the number of bees contained in the various colonies, and it is only fair to assume that the greater the number of bees the more stores will there be required. But in actual practice I have found that in an extra strong colony the bees have not consumed any more stores than one of ordinary strength, the extra number of bees keeping up the warmth of the hive, so that less food was required.

Some bee-keepers are successful in wintering a small number of bees on four or five standard frames, or in small straw skeps. In that case much less stores are required. A strong colony should have at least 20 lbs. of stores, but 28 lbs. would be an advantage, as it is better to err on the safe side, and provide too much than too little. Bees should be fed in the evening when all is quiet in the apiary, as robbing is very prevalent at this season.

FEEDERS.

A good feeder is a necessity for autumn feeding. For spring feeding an inverted bottle, or a small feeder of any description holding 1 lb. of syrup, will answer the purpose admirably. But for autumn feeding it is much better to have a rapid feeder, so that a strong colony may be given the required quantity of syrup in a short space of time. For this purpose I have found nothing better than the Canadian feeder. This is very simple in construction, being made of a number of slats of wood, which are fixed into a frame, and then placed in a tin-lined box. The bees gain access to the food through openings on each side underneath, and are prevented from escaping by a wooden lid. This may be slipped along when a further supply of food is necessary, which may be poured into the receiver at the end without inconvenience to the bees. They may be made of any size, but those holding 12 lbs. of syrup I have found the most useful. The Canadian feeder may be obtained from Messrs. Geo. Neighbour and Sons, 127, High Holborn, London, or from any dealers in bee appliances who advertise in the *Journal of Horticulture*.—An English Bee-keeper.

—— Tropical Botanical Station.—There seems some probability that Jamaica may be selected by the American Commission for the site of the proposed Tropical Botanical Station. Profs. MacDougal and Campbell have restricted themselves in their tour of investigation to that island, and have expressed themselves as well satisfied with the conditions of the rich and varied vegetation there found. The Director of the Botanical Department, Mr. W. Fawcett, is prepared to render every assistance in the furtherance of the object.—("Nature.")

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," 8, *Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Moving Seedling Briars Budded in July (*An Amateur*).—It is hardly safe to move them until the latter part of September, and only then if the weather be moist, keeping them out of the ground as short a time as possible. We have, however, moved similar plants at the middle of the month, and by watering and shading for a few days had an excellent result. Of course, the early part of November is the better time, but under the circumstances we should not hesitate to move them, lifting carefully, during the first moist weather in next month.

Insects on Stems of Cucumber Plants (*H. W. P.*).—The "insects" are members of the scorpion family (Scorpionidæ), and belong to the sub-family of false scorpions (pseudo-Scorpiones). It is Chelifer Geoffroyi and perfectly harmless to vegetation, indeed it lives on mites and young woodlice, being very useful in keeping down root-mite (Rhizoglyphus echinopus), a common cause of Cucumber plants, becoming sickly and even dying off, as the saying is, without cause. For this pest use soluble phenyle, 1 part in 96 parts soft water, or 1 gill ($\frac{1}{4}$ pint) to 3 gallons of water, applying as in an ordinary watering.

Pear Leaves and Insects (*G. S.*).—The leaves are eaten by the larvæ or caterpillars, commonly called slug worms, of the Pear sawfly (Selandria atra). Dust the tree on the upper side of the foliage with freshly burned lime, using no more water in slaking than necessary to cause it to fall to a fine and apparently dry powder, using when cool. The creatures may throw off the first coating of the lime, like a slug; but if repeated in about half an hour the second dressing burns them without any injury to the foliage. This old-fashioned dressing is better than dusting the leaves with tobacco or hellebore powder, as there is nothing in it to interfere with the use of the fruit; but the others are very objectionable, though efficacious, when there is any fruit ripening, or near thereto, as unless washed off by rain it is not useable. Similar remarks apply to soluble petroleum in solution, also tobacco water; otherwise these are very effectual. We, however, advise the lime.
